THE DIET IN TYPHOID FEVER.[1]

BY MORRIS MANGES, M.D.,

PROFESSOR OF GENERAL MEDICINE, NEW YORK POLYCLINIC; VISITING PHYSICIAN TO MOUNT SINAI HOSPITAL, NEW YORK.

IN view of the unanimity which prevails among medical writers on the subject of the diet of typhoid fever, it may seem surprising that this subject requires any discussion at all. That this unanimity is so marked among authors in all countries may be attested by a perusal of even the latest editions of the text-books and systems of medicine. Indeed, so accomplished a clinician as Chantemesse, in the celebrated "Traité de Médecine" of Charcot and Bouchard, dismisses the whole subject of the diet in typhoid fever in five lines. Nearly all writers are agreed in maintaining that the diet during the febrile stage shall consist either of milk alone or some preparation of it, beef-juice, or tea, or bouillon, gelatins, meat peptones, somatose and similar preparations, eggs, various gruels and broths, and alcohol; also a few vegetable- and fruit-juices. But on one point they are one and all unanimous, that under no conditions shall solids in any form be allowed to the febrile typhoid patient, and that even in the administration of liquid foods especial care shall be taken that these be chosen with reference to their blandness and to the amount of residue which is left after they have been digested in the stomach. One writer has even gone to the extreme of stating that even milk itself ought not to be allowed, since this is a good culture medium for the typhoid bacilli, and hence he has recommended preparations of malt, since it has been shown that the typhoid bacilli do not thrive in this medium.

As to the diet after defervescence, writers are again quite unanimous in stating that no solids of any kind should be administered until at least seven to ten days have elapsed after the establishment of a normal temperature; and when the fluid diet is departed from at this stage, the utmost care should again be exercised in the selection of bland articles of nourishment. It is true that a few writers, among whom we may mention Peabody of this city, have recommended that meat be administered as soon as the temperature reaches the normal line, yet such has been the fear of the febris carnis that these teachings have for a long time stood alone. The fact remains, therefore, that the general consensus of opinion is that the patient in typhoid fever shall be kept upon a liquid diet as long as there is the slightest possibility of the existence of ulcerated areas in the intestinal tract.

But there is another side to this question. The observations which have been reported, it is true, do not include a very large number of cases; yet they have been conducted on such careful lines that they are well worthy of attention. Of these recent publications I may mention that of A. J. Barr,[2] of Leeds, England, who reports his observations upon cases of typhoid fever in which the patients were fed with bread and butter, minced meat, and ordinary mixed diet, even though they had a temperature of 104° F. So far from doing the patients any harm, he even claims that they were benefited thereby. His observations were based on thirty-one cases, of which only three ended fatally; and to these three patients he had never been able to give solid food. He lost no case in which early full feeding was adopted, and his own mortality was not so great as the average mortality of the hospital (that is, of the Leeds General Infirmary). Relapses occurred in two of the thirty-one cases (six per cent).

Much more striking is an elaborate report that comes from Russia. Bushuyev, being fully convinced of the desirability of feeding patients with typhoid fever as fully as possible, concluded to have a comparative test made of this method, and arranged with his colleague, Sartsievich, that all the cases of typhoid fever which were admitted to the hospital in the year 1896-97 should be compared from this standpoint. Accordingly on the one division only milk (two quarts every twenty-four hours), one or two eggs soft boiled or in Stokes' mixture, were allowed to the patient, while on the other the full diet, the details of which will be stated below, was given. The results were as follows:

	Bushuyev	Sartsievich.
Whole number of patients.........	80	74
Recovered	72 (90 p.c.)	65 (87.8 p. c.)
Average day of illness on entrance in the hospital.	7.5	5.8
Average day of entrance to division..................	8.4	8.3
Day on which recovery was complete.....................	49.5	55
Number of days spent in hospital.	42	49.2
Days of fever in hospital........	18.9	22.3
Dismissed incapable of duty.....	6 (8.3 p.c.)	10 (15.4 p.c)
Died......	8 (10 p.c)	9 (12.1 p.c.)
Average day entrance to hospital.	8.5	5.8
Average day of entrance to division....	9.1	8.4
Day of death (average)	28.6	26.7
Number of days between entry and death...................	20 1	19.4

Bushuyev argued that those who objected to feeding based their objections not so much on the insufficiency of the digestive juices as the danger of hemorrhages. He argued that the changes which result in perforation rarely come on suddenly, but occur gradually; furthermore, that the lesions are so far removed from the stomach that by the time the foods, even those hard to digest, reach these areas, they are so far changed that one can hardly imagine that they could injure the intestines. Wholly indigestible substances such as fruit seeds or skins, which might injure the gut, are as a rule so rolled up in mucus or intestinal contents as to be harmless. Autopsies on cases of typhoid fever on the thirtieth day or later, in patients who had been liberally fed, showed that the intestines were in the same condition as under ordinary typhoid diet. That the cause of perforation is not the character of the food, but the nature of the ulcer, is asserted by Bushuyev, since one never hears of perforation of the tuberculous ulcer due to food. He also absolutely states that he knows of nothing to support the view held by some, that injury to the intestinal walls by solid food might provoke a re-entrance of the bacilli, and increase the frequency of relapses.

---

[1] Read before the Metropolitan Medical Society, November 28, 1899.

[2] British Med. Jour., 1897, vol. i., p. 125.

From the table of supplies open to him, Bushuyev devised the following plan for feeding typhoid patients, which he carried out for two years:

7 A.M. Tea with roll.

8 A.M. 400 c.c. of soft (liquid) oatmeal, barley, or wheat porridge with butter.

9 A.M. One or two boiled eggs, soft or hard, as the patient desires.

10–11 A.M. A glass (200 to 220 c.c.) of milk with roll, one-half a cutlet, and a bit of boiled meat (160 to 168 gm.).

12–12:30 P.M. A plate (220 c.c.) of chicken soup or a bowl of ordinary soup, sometimes with a bit of chicken from the soup, and a small cup of kisel (a sort of sour jelly); rarely a little preserved fruit.

3 P.M. Tea with a roll.

6 P.M. A cup of chicken or beef soup; semolina pudding or milk; a bit of chicken.

8 P.M. Milk with a roll.

During the night: Coffee or tea with milk two to four times; coffee with cognac.

For dinner or supper the white bread may be replaced with black (with the crust), and the soup by a thick wheat gruel. Many patients prefer boiled meat to cutlets, and the ordinary soldier's soup to hospital soup and gruel. The milk is generally boiled; occasionally it is given in the form of junket. As to beverages, the patients were allowed cold water, boiled or unboiled, cranberry juice, milk of almonds, small amounts of beer, and kvass. The cranberry juice was particularly grateful to the patients. In addition the patients received from one to three ounces of wine in the morning, and every two hours half an ounce of Stokes' mixture.

Bushuyev naively states that had he had a greater variety of articles of food he could have excited the appetites of the patients, so that in some instances they might have eaten more. As it was, some complained of insufficiency of bread. He was also unable to give the patients as much milk as he wished.

During the year 1897 under this diet he lost twenty-six out of three hundred and eighteen patients, or 8.2 per cent. During the years 1888 to 1897, the deaths from typhoid fever at the military hospital at Kiev varied between 10 and 19.3 per cent. The mean average in ten years was 12.4 per cent., three hundred and fifty-eight deaths in twenty-eight hundred and eighty-seven patients. Thus in 1897 with a mixed diet the death rate was materially less than for the ten years previous.

He declares enthusiastically that under this treatment the general condition of the patients was far better than that of those kept on exclusively fluid diet. The common complaints were scarcely ever heard. At meals the patients were uncommonly wide awake, and even those that were ill sat up in bed, begged for food, and ate with much satisfaction Only a few had to be fed by nurses. If one observed the patients at mealtime, he wholly forgot that they were seriously ill, with temperatures above 39° C. (102.5° F.). The visitors in the ward at meal-times were amazed "by seeing almost no typhoid-fever cases."

He states further that during the first hours in the ward the patient lies in a motionless condition, failing to answer questions and refusing food; but if one succeeds in some way or other in persuading him to eat a bit of meat or cutlet, or an egg, he begins immediately to show some interest in the surroundings. In a few days, often within a day, no trace of the typhoid condition remains. Unfortunately, it is impossible to persuade all typhoid-fever patients to eat. Attempts at forced feeding cause vomiting. Every care should be directed toward stimulating the patient's appetite, and to avoid disgusting him by what is brought before him.

When the patient enters in an unconscious condition he should be given as much of a liquid diet as he can take without vomiting, and if it be impossible to feed him by the mouth, he should be fed through the nose with a tube.

The tongue and lips remain in relatively good condition; there are no unpleasant gastric or intestinal symptoms. The bowels are often constipated, and pea-soup stools occur only in cases fed with milk and bouillon.

As regards complications, it is to be noted that intestinal hemorrhage is not more frequent during a solid diet than under exclusive liquids. Thus Bushuyev did not lose a single case from intestinal hemorrhage.

In 1897, among three hundred and eighteen cases there were only four instances of hemorrhage, *i.e.*, 1.7 per cent., whereas in the statistics of others it varies from two to ten per cent. Of the four patients with hemorrhage, two died, and it is to be noted that of these four patients only one received solid diet, two entering the hospital in so serious a condition that they had to have forced liquid feeding, and the other was that of a physician who preferred to be fed upon liquids. Perforation occurred in the last two years only once in five hundred and nine patients; that is, .19 per cent. The other authors estimate it from 1.25 to 3.04 per cent. General peritonitis occurred only twice.

The loss of weight in these patients was less than that which occurred in those on a more restricted diet The general condition was so good that they preferred as a rule to walk to their tubs and to the closet. Long before the end of the fever they got out of bed, and there was much difficulty in making them lie down. In summer they went out into the garden almost on the first day of the febrile condition.

Dr. Thayer, whose abstract of this paper in "Progressive Medicine," 1899, vol. i., p. 328 et seq., I have quoted so liberally, in commenting on it states that both reasoning and the figures are such as to make us reflect. He adds that if a more liberal diet than that afforded by the purely liquid regimen could be assimilated, the patient's strength would hold out materially better, and in diphtheria and pneumonia or febrile tuberculosis we endeavor to feed the patient as fully as possible on a simple, easily absorbable, and nourishing diet; but in typhoid fever we are restrained by a vague fear that any departure from the customary regimen is for some reason or other dangerous.

Thayer believes that indiscretions of diet may produce sudden rise of temperature with alarming symptoms, but he has never seen anything to show that this is more common in typhoid fever than in any other similar condition.

The only other elaborate reports which have recently been published on the use of solid foods in typhoid fever are those of Dr. F. C. Shattuck, of Boston, which were published in 1897, and the recent address of Dr. R. H. Fitz, of Boston. Shattuck's line of argument is very similar to that of Bushuyev, and his results are equally striking. He was led to take up this line of treatment as a result of having accidentally fully fed a number of typhoid-fever patients, the true diagnosis of which was not made until some time afterward. These results were so strikingly favorable that he was led to adopt a fuller regimen in the treat-

---

[1] Jour. Amer. Med. Assoc., July 10, 1897, p 51.

ment of his cases at the Massachusetts General Hospital. The statistics which he reports are most satisfactory.

Shattuck, after arguing against the fallacy of the old doctrines of depletion in acute febrile disorders, urged that although typhoid fever was a self-limited disease, yet its long duration rendered it necessary that, inasmuch as we could not directly attack the cause of the disease, our duty was to support the patient's strength to the utmost by maintaining nutrition at the highest level. We have no fear of feeding febrile patients in other diseases, and he calls attention to the forced feeding in the suppurative fevers, whether tuberculous or not. Furthermore, he says that no matter how we feed a patient there will be intestinal peristalsis, and the waste products must pass over the ulcerated areas. Furthermore, he does not accept the old idea that relapses are due to dietetic errors alone, but that nervous excitement, undue fatigue, etc., also cause rises of temperature; nor does he believe that these factors can cause fresh infection by bacilli. Thus for twelve years, from 1886 to 1897 inclusive, three hundred and eighty cases were under his treatment. From 1886 to 1893, two hundred and thirty-three were upon exclusively milk diet, with a mortality of ten per cent.; from 1892 to 1897, one hundred and forty-seven were upon a more liberal diet, with a mortality of 8.1 per cent. Shattuck admits that the number of his observations is small, and that other factors in the treatment, such as the introduction of hydrotherapy, may have had something to do with his better results; but one factor remains, namely, that the more liberal diet at all events did no harm. Shattuck does not advise eating everything, but he insists that we should treat the patient and not the disease, that we should feed him with reference to his digestive powers and not with reference to the fever, and furthermore, that there is no increased danger of irritation from food which leaves no irritating residue, and which cautious trial shows is digested without disturbances. His diet includes:

1. Milk, hot or cold, with or without salt, diluted with lime water, soda water, Apollinaris, or Vichy water; peptogenic and peptonized milk; cream and water (*i.e.*, less albumin); milk with white of egg, buttermilk, koumyss, matzoon, whey; milk with tea, coffee, or cacao.
2. Soups—beef, veal, chicken, tomato, potato, oyster, mutton, pea, bean, squash; carefully strained and thickened with rice (powdered), arrowroot, flour, milk or cream, egg, barley.
3. Mellin's food, malted milk, carnipeptone, bovinine, somatose.
4. Beef juice.
5. Gruels—strained corn meal, crackers, flour, barley water, toast water, albumen water with lemon juice.
6. Ice cream.
7. Eggs, soft boiled, raw, egg-nog.
8. Finally, minced lean meat, scraped beef; the soft part of raw oysters; soft crackers with milk or broth; soft puddings without raisins; soft toast without crust; blanc mange, wine jelly, apple sauce, and macaroni.

In the admirable address[1] at the recent general discussion on typhoid fever at the last meeting of the New York State Medical Association, Dr. R. H. Fitz, of Boston, presented the statistics on typhoid fever at the Massachusetts General Hospital, extending from 1821 to 1899. In the course of this address, among other things, he directed especial attention to the influence of diet upon the course of typhoid fever, upon the general mortality, the occurrence of hemorrhage and of perforation:

"For the thirty years from 1839 to 1869 the diet of the patients was liquid, the fluids often containing some farinaceous ingredients. From 1869 to 1879 beef tea and beef juice were largely used in addition to the milk, and from 1879 to 1899 the liquid portion of the diet has been chiefly milk. Between 1893 and 1898 the patients under the care of Dr. Shattuck [namely, the cases which have been referred to above] have received, in addition to the milk, minced meat, raw and soft-boiled eggs, macaroni, soft crackers, toast, and puddings. Patients under the care of Dr. E. G. Cutter, during a like period, have been fed on skimmed milk, buttermilk, eggs and milk, albumen water, chicken broth, and beef juice with barley water. The mixed foods were so strained as to be freed from solid particles. During the thirty years of liquid farinaceous diet, the average mortality was 14.1 per cent. In the milk and beef-tea decade it was 16.6 per cent., although in the immediately preceding liquid farinaceous decade it was 15.9 per cent. From 1879 to 1899, among those patients using milk as the principal article of food, the mortality was 14.6 per cent., which was about the same as during the period of liquid farinaceous diet. The mortality was only 11.3 per cent., however, among the patients between 1893 and 1898, who were fed upon the liquid and soft solid diet prescribed by Dr. Shattuck. This mortality compares very favorably with that of 15.1 per cent. noted among the patients using a largely milk diet, and with a 16.6 per cent. mortality occurring among patients taking strained, starchy, and proteid fluids. As regards the occurrence of hemorrhages, it was noted among patients living on a milk diet in 10.6 per cent.; among those fed on proteid and amylaceous fluids it was sixteen per cent., while it was only nine per cent. among the patients living upon fluids and soft solids. The inference from this comparison is that a diet of soft solids not only does not provoke an intestinal hemorrhage, but also rather lessens the tendency to this complication. On the other hand, the strained mixed diet may increase somewhat the frequency of the hemorrhages.

"The frequency of perforation could be noted with sufficient accuracy to permit comparison, only in the cases reported within the past thirty years. From 1869 to 1879 the average frequency of this occurrence was 1.1 per cent.; from 1879 to 1889 0.3 per cent., and from 1889 to 1899 1.6 per cent. These differences are so slight as to make it doubtful if dietetic treatments have had any effect in modifying the frequency to these grave complications of typhoid-fever patients. Of ten patients with perforation, between 1893 and 1897, five, or 2.8 per cent., were using a largely milk diet; two, or 1.8 per cent., the strained liquid diet; and three, or 3.4 per cent., were fed upon liquid and soft solid diet.

"As to frequency of relapses, careful thermometric records having only been made at the hospitals since 1869, it is possible to make comparisons only since then. It is to be noted that the frequency of relapses has increased from 8.7 per cent. of the decade from 1869 to 1879 to 13.6 per cent. in the next decade, and 11.3 per cent. in the last decade, namely, 1889 to 1899. This frequency may possibly, as has frequently been maintained, be due to hydriatric treatment of the disease.

"It is to be noted that relapses were rather more frequent among patients living upon a largely milk diet, since among them the ratio of relapses was 13.1 per cent.; it was 11.1 per cent. among patients living upon strained proteid and amylaceous diet, and 10.2 per cent. among the patients fed upon fluids and soft solids." Fitz, therefore, in his conclusions maintains that a considerable variety in the diet may be permitted not only without detriment, but also with possible benefit to the patient.

---

[1] Boston Med. and Surg. Jour., Nov. 23, 1899. I am indebted to Dr. Fitz for his courtesy in sending me advance sheets of his paper.

My own experience in this field is, I regret to say, more limited than I would like. There are many reasons for this small number, one being that the number of typhoid-fever cases is usually small during the greater part of my service at the Mount Sinai Hospital (*i.e.*, February 1st to August 1st), and, furthermore, I did not begin this plan of treatment till the middle of May. This year's epidemic, also, was peculiar both in the comparatively small number of cases and its severity. Never have I seen such a series of bad cases; the tendency to complications was unusually great, among which pneumonia was the most prevalent. This is shown in the hospital statistics of the cases of typhoid fever treated this year up to November 24, 1899:

Total Number 90.		Full Number. Per Cent.	Number on Liquid Diet, 82. Per Cent.
Total deaths........	11	12.2	13.4
Total relapse........	14	15.5	14.5 (12 cases.)
Total perforation....	4	4.4	4.88
Total hemorrhage ...	3	3.3	3.5

Mortality of hospital for 1896, 7.6 per cent.; for 1897, 9.57 per cent.; average mortality, 1893–1897, 11.09 per cent.; average per cent. of relapse, 1893–1897, 8.42.

The percentages for the series of eight cases on fluids and soft solids are not given, as it is scarcely justifiable to present any results based on such a small number. It is to be noted, however, that there were no deaths, hemorrhages, or perforations. The two relapses will be discussed later on.

This series, as stated, included only eight cases, four males and four females, the ages of whom ranged from sixteen to twenty-five years. The plan of treatment was that ordinarily pursued at the hospital, *i.e.*, a minimum amount of medication, usually including only dilute hydrochloric acid and stimulants, unless some special indications should arise. Plunges at 90° to 80° F. or cold packs were the routines for high temperatures. The majority of the cases were of the severe type, as their subsequent course proved.

The diet allowed was the soft diet of the hospital. This includes soft boiled eggs, milk, milk toast, custard, strained jellies, chicken, rice, farina, strained oatmeal and other cereals, softened soda crackers, baked potatoes. One and all the patients relished their food, although I must confess it at first seemed somewhat uncanny to see these patients sitting up in bed, trays in front of them, and with contents rapidly disappearing. That they digested the food was proven by the constant supervision of the stools; it is also to be noted that diarrhœa was not present in any larger proportion than is usual in this disease. In several of the cases there was constipation; two of the patients had two or three soft stools daily. The tongues were always moist, whether they were coated or not. In other words the food was tolerated in every way, and that it was absorbed was manifest from the fact that, as a rule, these patients emaciated less rapidly than the others who were under liquid food treatment at the same time. The better nutrition of these patients was also demonstrated by blood counts which were made for other purposes on two of them, both of which ran severe courses; one of them was complicated by pharyngeal diphtheria. On the twelfth day there were 4,280,000 erythrocytes, and 12,000 leucocytes. In the other case, in the fifth week, the examination showed 5,087,000 erythrocytes, although the temperature was still elevated.

There were no deaths, although according to the high average mortality of the hospital for this year we should have expected at least one death. This is remarkable in view of the severity of the cases, diphtheria, pyelitis, mastitis, and a marked psychosis being among the complications. There were no hemorrhages, since we can eliminate the few drachms of blood which were once reported in one case. Perforation and indeed all peritoneal symptoms were absent. Likewise there were no thromboses.

Relapses were reported in two cases. Of these one occurred three weeks after the patient's discharge from the hospital, and can therefore hardly be attributed to the increased diet. The other relapse was that of a robust domestic, who had a mild primary attack, but who subsequently had two severe relapses. It is to be observed that in her first relapse she was fed on milk alone. This apparently did not prevent her having the second relapse.

Whether this high percentage of relapses (twenty-five per cent.)—which, it is to be observed, is higher than the average of the other hospital cases for this year—is a coincidence or not, I will not discuss, since it would be rash to draw conclusions from eight cases. The larger statistics of Fitz and Shattuck demonstrate that relapses are less under full diet than they are on a liquid régime. On the other hand, if we eliminate the one case in which the relapse occurred three weeks after discharge from the hospital, as we are justly allowed, then the percentage would be twelve, which would be close to the hospital average.[1]

Having thus presented the leading facts which have thus far been presented on this side of the dietetic question, let us review the grounds on which the necessity of a liquid or soft diet in typhoid fever has been so generally emphasized, so that we may see the practical reasons pro and con. In no other way can any definite conclusions be reached. The subject is deserving of discussion, even though all the text-book writers are unanimously opposed to any change. For a long time many were opposed to the bath treatment; to-day it maintains its popularity even though statistics show that hemorrhages and relapses are probably more frequent under this treatment than they ordinarily are. The benefits from the treatment far outweigh the disadvantages of the method. In medicine nothing is fixed, and progress is alone possible by constant revision, even of that which at the time is universally accepted.

The fundamental principle is that typhoid fever is a general infectious disease, the chief and most important feature of which is the lesions in the intestines; and since these lesions are accompanied by an ulceration more or less deep of the intestinal walls, every effort should be made to secure the utmost possible rest for the gut, both in the nature of the food residue which passes through the involved intestine, and the amount of distention to which its walls may be subjected by undue fermentations.

The extent to which these views now prevail in the minds of some of the very best authorities may be inferred from the statements made by some of them that constipation is the ideal state, and that the bowels should be moved as little as possible. But it is to be answered that typhoid fever is something more than an intestinal lesion. The bacilli can be found in the blood as early as the fifth day, and are in the spleen and other organs at an even earlier period. Later on they may be found in almost any part of the body. This has been well shown by Keen, in his elaborate synopsis on the various parts of the body in which Eberth's bacillus has been found.[1] This list includes the blood, the endocardium and endocardial vegetations, the walls of the arteries and veins, thrombi, muscles, the connective tissues, the skin, the synovial sheaths of tendons, joints, the bones, the brain and spinal cord, thyroid gland, parotid gland, orbit, middle ear, lungs, pleura, peritoneum, liver, the gall bladder and bile, the spleen, the mesenteric glands, the kidney, the urine, ovaries, testicles and epididymis, and even in the placenta and fœtus.

---

[1] In the discussion a number of cases of typhoid fever were reported in which the patients were, for some reason or another, fed upon solids throughout the whole course of the disease. Among these was one narrated by Dr. Leszynsky: the patient, being the wife of a doctor, thought she knew all about feeding, and insisted upon a diet of tongue and ham sandwiches, etc. She could not be dissuaded, her chosen diet was regularly given to her; the course of the disease was uneventful. Dr. Kubin stated that while he was house physician of the German Hospital scraped ham was often allowed without any bad effects. Dr. Koplik said that at Bellevue Hospital Dr. Alonzo Clark and Dr. Delafield not infrequently permitted scraped meat. I may add that during a recent conversation with Dr. Janeway on this topic he told me of a patient at Bellevue Hospital who insisted on being fed on corned beef and cabbage, no harm resulted, since his case pursued the ordinary course.

In his most recent paper on the diagnosis of typhoid fever, Osler[2] lays special stress upon the necessity of recognizing the general infection in typhoid fever, since it is the failure to recognize this that so often leads to errors in the early diagnosis of this disease. Thus the toxæmia from which the patient suffers is not alone due to the poisons which are produced by the bacilli in the intestine, but is due to those which are elaborated in the other organs.

Furthermore, typhoid fever is not alone due to the typhoid bacilli, but it is a mixed infection in which the colon bacilli, staphylococci, streptococci, and other micro-organisms play a most important part; hence the fever in the early stages of typhoid fever is entirely due to the typhoid infection, but in the later stages there is the added factor of the mixed infections which occur in the ulcerated areas in the intestines and elsewhere. Moreover, not a few cases have been reported in which the most careful examination at autopsies has failed to find the slightest involvement of the intestines.[3]

Another important fact which must not be overlooked is this: that the severity of the intestinal lesion cannot be inferred from the amount of diarrhœa. The deepest ulceration may be accompanied by constipation, and furthermore a marked catarrhal condition of the mucous membrane with only moderate ulcerations of Peyer's patches may be accompanied by an unusual number of intestinal evacuations. The difficulties attending this question may be inferred by the following quotation from Hare:[4]

"The consensus of opinion seems to be that diarrhœa is usually more active in serious cases. Whether this is an instance of purging as an effort of elimination, a favorite theory of those who are fond of using purgatives and so-called intestinal antiseptics, with the idea that by so doing they eliminate poisons and prevent their formation, or whether it is a manifestation of severe ulceration of the bowel with an associated catarrh, is difficult to determine. Ord agrees with the view that diarrhœa is usually associated with ulceration, and his opinion has been confirmed by the autopsies he has seen. Peabody states the case exactly opposite to this view. That Ord's view is not correct seems proved by the fact that advanced ulceration is often found in cases which have not had diarrhœa, and cases of marked diarrhœa are seen in which the autopsy does not reveal much intestinal ulceration. In Bryant's case diarrhœa was active, yet no intestinal lesions were found. In all probability diarrhœa is neither indicative of a severe nor a slight attack in many cases, although if it is violent the exhaustion produced by the discharges may seriously imperil the patient's chance of recovery."

Finally it is urged, but by no means proven, that administration of solids necessarily increases diarrhœa or tympanites. The contrary is often true. Bushuyev and Shattuck especially note that many of their patients were constipated; in my own cases on solids the same was frequently reported.

The opponents of the administration of solid food forget that, no matter how carefully the diet is regulated, the intestinal contents must pass over the ulcerated areas; that peristalsis must take place. Its advocates argue that the former lose sight of the fact that fortunately the favorite site of the lesions in the intestines is the ileum, especially its lower part, less frequently the jejunum and the colon, hence food even of a solid nature must have been fairly well digested before it reaches this part. The other arguments advanced have been sufficiently referred to in the statement from Bushuyev given above. If any further details are needed upon this question as to whether peristalsis is especially injurious, one may recall the various procedures of the so-called eliminative treatment of the disease.

The point upon which special stress must be laid is that typhoid fever is a general toxæmia, and it is to this rather than to any particular lesion that we must direct our attention and regulate our diet. Barr has urged that ulcerations in the intestine are like ulcers elsewhere, and that they will heal much more rapidly when the blood and the tissues are well nourished. The disease being one of long duration, the patient is enabled to combat it far better if his general nutrition has been kept at the highest point possible under the circumstances. That this plan is feasible is shown by the results narrated by Barr, Shattuck, Fitz, and Bushuyev. My own limited experience confirms it. The general mortality is decidedly less under liberal diet that on liquid or restricted soft foods, as the statistics already given sufficiently prove, so far as statistics in so variable a disease as typhoid fever will enable one to judge.

The second ground of contention is the presence of the fever. Those in favor of liquid diet maintain that the digestive secretions are lessened, and hence the quantity of saliva, gastric juice, pancreatic juice, and bile is entirely insufficient to digest anything but the simplest foods. Furthermore, the lack of appetite prevents the administration of anything except liquids; even the patient's appetite is not a safe guide, for he may simulate hunger under the false impression that his recovery will be facilitated if he takes a large quantity of nourishment. Thus the fact is emphasized that it is one thing to introduce food into the body, but that it is quite another to digest and assimilate it. But, say the opponents of these views, we feed other fevers no matter what their nature may be, whether they be the prolonged fevers of tuberculosis, of suppuration, or other conditions; indeed, we make it a point to do everything which we can to get the patient to take the maximum quantity of nourishment. Be these views as they may, all are agreed that there is such an enormous waste of the body albuminoids and fats that we must strive as far as possible to replace these lost tissues in the diet, and at the same time we must seek to protect the remaining tissues from too rapid destruction. The general consensus of opinion is, that this can be amply provided for by increasing the quantities of liquid food, our guides being the amount of residue which is found in the stools, the general condition of the nutrition of the patient, and the state of his mouth, etc. That this is not fully accomplished is shown by the marked emaciation which always accompanies typhoid fever. Voit has shown that the caloric value of three or four

[2] New York Med. Journal. November 11, 1899.

[3] Biggs (Med. News, November 11, 1899) has well shown the fallacy of calling this disease enteric fever.

[4] "Medical Complications and Sequelæ of Typhoid," February, 1899, p. 121.

pints of milk daily is not sufficient to feed and replace the waste in this disease. Furthermore, no food produces more virulent toxins than does milk. Every pædiatrist is emphatic in directing attention to this important point in the treatment of gastro-enteric disorders in children. The imperative need for more nourishment is only too frequently attested by the pitiable cries for food so often uttered by these patients, even before defervescence. Although the diet allowed by Bushuyev is that of an enthusiast who has gone to the other extreme, yet the fact that his patients thrived on it proves that an increased diet may not alone be eaten by this class of patients, but may also be fully digested and assimilated.

The third point of contention is the danger of hemorrhage. So far as the limited number of cases quoted above will permit any judgment, it must be confessed that it would seem that the administration of solids has not increased the frequency of hemorrhage. Indeed its frequency is distinctly less in the series of Bushuyev, Shattuck, and Fitz. Thus Bushuyev had only four cases in his series of three hundred and eighteen, *i.e.*, 1.7 per cent., but of these one only had solid food, thus reducing the percentage to 0.3 per cent. Fitz reports nine per cent. of hemorrhage of those upon fluids and soft solids, as opposed to sixteen per cent. among those on liquids. There were no hemorrhages in my own cases. On the other hand, so eminent an authority as Curschmann[1] reckons dietetic errors among the exciting causes of intestinal hemorrhages.

Fourth, the danger of perforation does not seem to bear any relation to the character of the food administered, at least so far as the statistics which are available will permit any judgment. Nor indeed is this surprising, for perforation is due to the nature of the lesion, to the progressive ulceration rather than to anything else. It has repeatedly been shown that perforation bears no relation to the severity of the general symptoms. It is true that a gut which is unduly active in its peristalsis, and is unduly distended by gas, will be much more apt to rupture under these conditions than when they are more favorable. As this subject has already been sufficiently gone into, it need not be discussed at any greater length here.

Fifth, the subject which is apparently much less difficult of determination from statistics is the occurrence of recrudescences of fever and relapses from the administration of food. Yet in a disease which is as protean in its manifestations as typhoid fever, in which the collected statistics even of enormous numbers of cases show such great variations in the frequency of relapses, in which the epidemics from year to year present the most varied phenomena, one must be reserved in passing judgment. We do not yet know why one case relapses and the other does not. The *post hoc* and *propter hoc* must be carefully kept asunder; for undue mental excitement or even fatigue, the administration of drugs (Hare mentions the occurrence of recrudescences after full doses of strychnine), the change from one liquid to another, as has been claimed by West, and many other occurrences may cause relapses. Hence in a given case one can never be certain that the relapse which occurs has been due to the administration of food. Still the general consensus of opinion is that, in a large number of cases, relapses or recrudescences or fever have resulted directly from dietetic errors. Every physician who has had an extensive experience with typhoid fever has encountered numerous such examples. I am sure that every year I have seen cases of relapses which have apparently resulted from errors of diet. The most striking case of this kind which I can recall is that of a boy whose fever most persistently remained elevated. Search as we would, we never could find any cause for its protracted course. The death of the patient in the neighboring bed soon brought his fever to an end. It was then that we learned that this patient was surreptitiously supplied with fruit, cakes, etc., on visiting days, and taking pity on his neighbor he passed it over to him. Many of the relapses of this kind are due to another factor; *i.e.*, the patients are so famished that they ravenously devour what they can lay hands on, often doing so surreptitiously. Bread, fruit, and sponge-cake are the especial offenders in the case of hospital patients.

But is there any evidence to show that indiscretions of diet produce rises of temperature with unpleasant symptoms more frequently in typhoid fever than in other conditions? I can fully indorse Thayer's statement[1] already quoted, that "an indiscretion of diet may produce such symptoms in any condition of severe physical exhaustion," and that he "has never seen anything to suggest that it is more common in typhoid fever than in any other similar condition." Neither does Shattuck believe that relapses are due solely to dietetic errors. It must be distinctly remembered that relapses occur even on a strict milk diet. It is possible that relapses may take place more frequently under full feeding, just as they are reported more frequently in the Brand treatment. The question is one which is very difficult of solution, and time and a larger experience can alone solve it. The only available statistics are those of Fitz already quoted, *i.e.*, that relapses occurred in 13.1 per cent. on a milk diet, in 11.1 per cent. on a strained, proteid, and amylaceous diet, and in 10.2 per cent. on fluids and soft solids.

As to the question of the diet in convalescence, it follows that those who believe in full feeding have already solved it before defervescence has occurred. If the patient has been kept on liquids, my own experience inclines me to allow solids gradually at the earliest possible moment, the guides being the patient's general condition, the presence of hunger, clean tongue, and the absence of sloughs or much mucus from the stools.

The question of radical increase of diet may also come up at other times. Among these I may mention the unduly prolonged persistence of fever. Not a few of these cases are cases of inanition or starvation, the bodily and mental phenomena of which are not recognized as such, but are reckoned among the typhoid phenomena. A careful consideration of all the features of the case, and more especially an examination of the blood, will often reveal the true condition.

The most marked example of starvation which I have thus far encountered occurred in a case in private practice this spring. After having been for some time under the care of another physician, the bad condition of the patient led to a change of her medical adviser. I found the patient, a wildly maniacal woman, aged thirty years, with fever of 104.5° F.; pulse, 140; respiration, 38. Feeding was utterly impossible on account of her mania. There was no other recourse except to feed her by means of the stomach tube. This was easily effected with the aid of a gag. Within twenty-four hours the effect was almost magical: all the symptoms, especially the mental changes, were decidedly improved. Investigation of the diet on which the patient had been fed before I assumed charge showed that the nourishment which she had received was absolutely liquid, and of the most meagre character. I may add that the subsequent course of the case was most prolonged and complicated, and yet she recovered in spite of eighteen profuse hemorrhages, a lobar pneumonia, and saphenous thrombosis.

[1] *Loc. cit.*, p. 332.

In this connection I may be pardoned if I refer to the use of the stomach tube in typhoid fever. While there have not been many occasions on which its use has seemed necessary to me, yet I have never had occasion to regret its use. The indication has been uncontrollable vomiting. Careful lavage of the stomach, and the introduction of small quantities of predigested food while the tube was *in situ*, have given satisfactory results. We do not hesitate to use the tube in cases of strangulated intestines, after laparotomies, etc. Why should we hesitate to use it in typhoid fever, if the indication should arise? It need scarcely be added that such a procedure should be entrusted only to those who by constant practice are able to pass the soft stomach tube with the least amount of discomfort to the patient. At such a time and place the bungler ought to recognize his proper sphere.

There is still another point of which experience has taught me to recognize the value, *i.e.*, the importance of allowing intervals in which nothing at all is permitted to enter the stomach in patients whose feeding has been rendered difficult from fermentations, vomiting, etc. This is especially frequent when the diet has been entirely liquid; the stomach is ceaselessly deluged with liquids; its motility and secretion being diminished, its burden cannot be effectually disposed of; stagnation results with its coincident fermentation, and the familiar vicious circle is established. Rest to the organ is the simplest and best way to remedy this distressing combination.

In conclusion I would state that I have not touched on many other points in the dietetic treatment of this disease. This was done advisedly, since I believe I have presented enough to show the paramount need of physicians paying more attention to the diet in these cases. At present it is entirely too stereotyped, or it is not regulated at all, the simple direction being given to feed the patient on milk! If only a fraction of the energy which is now wasted in prescribing needless drugs were devoted to intelligent personal supervision of the diet, the patient would gain much; if another fraction of this same energy were given to securing proper disinfection of the stools, urine, bedclothing, etc., the patient's family and the community at large would be greatly benefited; and if still another fraction of this energy were devoted to a study of the diagnosis of typhoid fever, the profession at large would be spared the humiliation of being so frequently and so justly scourged for its ignorance on this most important topic. And, as a corollary, the patient's stomach would be spared many a task, and it would be left in condition to digest something more than the emasculated slops which are now tendered under the guise of many of the so-called foods!

Finally, I must add, lest I may perchance be misunderstood, that I do not advise that each and every patient be placed upon these less restricted diets, nor that every article of diet may be allowed. The question has not yet been sufficiently studied to justify one in giving any sweeping directions. Enough material has, however, been gathered by such trustworthy clinicians as Fitz and Shattuck to justify physicians, especially those who have the advantages of hospital services, in giving an extended trial to the more liberal feeding of typhoid-fever patients.

Rectal Adenomas.—According to Beach (*Philadelphia Medical Journal*, December 16, 1899, p. 1195), rectal adenomas may be hard or soft. They contain the constituent elements of the mucosa and submucosa. They may be benign or malignant. Benign in origin, they may become malignant. Early recognition, made possible by the newer methods of inspection, is of first importance.

TWO CASES OF TUMOR PRESSING UPON THE CAUDA EQUINA; REMOVAL; RECOVERY.[1]

By B. SACHS, M.D.,

PROFESSOR OF MENTAL AND NERVOUS DISEASE IN THE NEW YORK POLYCLINIC; CONSULTING NEUROLOGIST TO MT. SINAI HOSPITAL, ETC.

In the cases to be reported herewith, the symptoms pointing to intra-vertebral tumor were slight, yet definite enough to warrant prompt surgical interference. In both cases the neoplasm was found and successfully removed. The patients have been relieved of the distressing symptoms. In both the chances of life are far better than if the malignant tumor had been allowed to go on growing indefinitely.

Case I.—The first patient was seen by me September 23, 1899, in consultation with Dr. J. A. Wyeth, who will publish the full surgical details in his series of spinal cases.

Colonel J——, fifty-six years of age, married, a man of robust constitution, has been suffering for the past eighteen months from severe pains in the right thigh and leg, associated latterly with sudden and severe spasmodic contractions of the thigh muscles. He had been shot in the Civil War, the bullet passing obliquely through the upper portion of both thighs and out. His pains were suspected to be connected, possibly, with this old bullet wound, or to be of the ordinary neuralgic type (sciatic and crural). Anti-neuralgic measures had been employed by various physicians in the South without benefit to the patient, who was finally referred to Dr. Wyeth for further treatment. At the time of my first and the only examination prior to the operation, I was struck by the cachectic condition of the patient, by the violence of the pains, and by the frequent severe spasms of the muscles of the right thigh; these spasms being preceded, as a rule, by excruciating pain. The entire right thigh and leg were somewhat wasted, but the muscular power was in keeping with the amount of muscular tissue preserved. The patient could not state whether this condition had been developed during the past two years, or whether the limb had been wasted in consequence of the bullet wound, thirty-five years ago. As there was little if any paralysis, I was inclined to accept the latter theory, and did not allow the general atrophy of the muscles to interfere with the localization of the lesion. The pain, as described by the patient, was neuralgic in character, not markedly affected by the position of the limb, but was much more persistent than in ordinary neuralgias, and radiated from the lumbar region of the spine into the posterior portion of the entire extremity as far as the toes, and occasionally would go into the anterior aspect of the thigh. In walking, the lower portion of the spine was rigid and appeared to be a functional rigidity due to pain. The spinal column was not very sensitive at any part. Deep pressure upon the spinous processes of the second and third lumbar vertebræ produced some pain. On pressing even lightly at a point about one inch to the left and between these vertebræ, pain was excited, and this pain radiated down the leg in the same fashion and was exactly like the pain which the patient experienced at other times. This statement was made so positively that it had great weight, in view of the very moderate development of all other symptoms. The suspicion of a neoplasm involving the cauda equina was strengthened by the objective disturbances, however slight, of sensation. There was a distinct diminution, not a loss, of tactile pain and temperature sense in the posterior and upper inner portion of both thighs; pulling of the hair, slight pricks of a pin, blowing of breath upon the skin could not be readily distinguished; but more intense stimuli could be perceived. The right knee jerk was absent, the left normal and lively; both Achilles-tendon reflexes could not be elicited; there was no ankle clonus; the scrotal reflex of the left side was greatly increased; all other deep and superficial reflexes were about normal. The vesical and rectal reflexes were not impaired. The heart and kidneys were normal.

---

[1] Read before the New York Neurological Society, December 5, 1899.

The persistent neuralgic pains and the slight objective disturbances of sensation, though they had lasted nearly two years, formed a scanty basis upon which to rest a diagnosis of tumor; but the presence of a new growth was rendered more probable by the severe spasmodic contractions of the thigh muscles and by the production of pain exactly like those of which the patient complained, from pressure near the second lumbar vertebra. Moreover, the site of this painful area tallied perfectly with the portion of the spinal axis to which the objective sensory symptoms had to be referred. The absence of the right knee jerk and the atrophic condition of the muscles of the thigh and leg would have pointed to a lesion nearer the second lumbar segment; but these symptoms were accounted for by the old bullet wound. In the absence of vesical and rectal disturbances, and because of the strictly unilateral character of the symptoms, although the disease had lasted nearly two years, preference was given to the cauda equina, rather than to the lumbar segments, as the site of this lesion. That the neoplasm was extradural was also probable, for an intradural growth would surely have produced symmetrical symptoms referable to the cauda equina, and if intradural, the symptoms would be more symmetrical; the sensory and motor symptoms in the case were taken to be irritation symptoms of the anterior and posterior roots. At the conclusion of my first examination I urged Dr. Wyeth to operate at once for the removal of the growth which he was to find under the second or third lumbar vertebræ. The operation was undertaken on October 1st. A large incision was made from the third lumbar vertebra upward. Upon dissecting away the muscles from the median line, a small bulging mass was observed on the left side between the second and third lumbar vertebræ. The mass appeared so vascular that Dr. Wyeth exercised the greatest precaution not to injure it while removing the laminæ of the exposed vertebræ. Upon exposure of the spinal canal, a tumor, of the size of a small walnut, adherent to the dura and to the inner surface of the bones, was in evidence. This was removed in blunt fashion, without injuring the soft parts; the lamina had, however, been invaded by the disease. A microscopical examination of the mass proved this to be an alveolar sarcoma. The surgeon removed as much as was practicable of the diseased bony tissues, but whether or not the line of demarcation between healthy and diseased tissue had been reached could not be stated with certainty.

On the fifth day after the operation I had an opportunity of examining him. He was out of bed, and, for the first time in many months, was free from pain and able to walk about with comfort. The spasmodic movements of the limbs had ceased, and the most careful testing failed to reveal any objective sensory disturbances. It was evident, therefore, that these symptoms were due entirely to pressure of the tumor upon the strands of the cauda equina. The knee jerk has not returned, but this I hold to be due to the injury of years ago. The patient made an excellent recovery, returning to his home in the South a month after the date of the operation. He was free of pain, had full use of his limbs, and was evidently none the worse for the removal of two laminæ. It is, of course, possible that the patient may some day suffer a relapse —possibly from a deposit in some other organ—but he has been cured, apparently, of the spinal disease, and, if Bruns is right, a recurrence of the spinal affection need not be feared.

Case II.—In the second patient the difficulties of diagnosis were far greater and the disease was more advanced.

A. A——, thirty-two years of age, was admitted October 9, 1899, into Mt. Sinai Hospital, in the service of Dr. Alfred Meyer, who was kind enough to place the patient under my care. His father died of pneumonia; his mother is living and healthy. There was no history of any previous infection, and, according to his own statement, the patient has been moderate in all his habits. Ten years ago he was supposed to have pulmonary tuberculosis, and Dr. Loomis advised his going to Colorado. The patient spent two years in California, and evidently recovered from the disease which threatened his life.

The patient remained well until one year ago, when he began to feel shooting pains in the back and legs. They were most marked every second or third night. During the past six months the attacks of pain became more frequent, occurring during the day-time as well as at night. About six or seven months ago he noted a girdle sensation about the level of the umbilicus, which he experiences no longer. He has also noticed paræsthesiæ of the plantar surfaces of the feet, but only when walking barefooted. Three or four months ago, he thinks, there was anæsthesia on the outer side of the left leg. He states that a few months ago there was distinct double vision. Hearing, taste, and smell have always been normal. About six months ago his legs became unsteady, and the unsteadiness increased after an enforced rest in bed of six weeks. He experienced distinct pain while walking, and states that this was more marked in the left leg. During the last two months walking had become increasingly difficult. The patient thinks that the difficulty was due to the fact that he was unable to bear the weight of the body, not to a tendency to swaying. He never noticed any symptoms about the arms, but during the past six months has had a feeling of stiffness in the lower portion of the back, but did not know that there was any change in the configuration of the spine. There was tardy micturition, and occasionally the act was accompanied by pain. The patient is of the emotional order; many of his statements have had to be taken with a grain of salt; they were colored by the fact that he had been seen by a number of physicians, who had evidently questioned him closely in their endeavor to elicit the symptoms of tabes dorsalis, the diagnosis with which the patient had been sent to the hospital.

His condition at the time of my first examination, October 14, 1899, may be summed up as follows: Slight weakness of the external rectus, evidenced by slight lateral nystagmus-like movements on following the finger to the extreme left. The pupils reacted normally to light and during accommodation. Every passive movement of the eyelids was promptly perceived. There were no tremor of the tongue and no facial tremor. In the upper extremities not a single symptom was to be elicited. On the chest, back, and abdomen sensation was normal, and all the reflexes could be elicited. There was a distinct kyphos involving the twelfth dorsal and the upper three lumbar vertebræ. There was no pain on pressure over this area, except at one point about one inch to the left of the median line between the third and fourth lumbar vertebræ. Muscular power was evidently diminished in both lower extremities, the left leg being weaker than the right. But, in spite of his pain, the patient could be got out of bed and made to stand and to take a few steps, but his locomotion was difficult, and made doubly so by the fear of the pain accompanying it. Both knee jerks were absent. On the right side the plantar reflex was wanting; on the left side it was slightly present. Both Achilles-tendon reflexes were wanting. In the lower extremities the sensation was normal, except on the dorsal aspect of the left thigh, of the left half of the perineum, scrotum, and of the penis. In this area there was no absolute loss of any form of sensation, but there was distinct diminution of all. Heat and cold could be felt, but could not well be distinguished from one another. There was no marked interference at this time with the vesical and rectal reflexes, and no other symptoms of any account were noted, except that the lungs seemed suspicious. Both apices were dull, and there was distinct broncho-vesicular breathing at the left apex, with crepitant and subcrepitant râles. These râles were also heard over the entire left chest anteriorly.

In view of the normal condition of the pupils, the absence of strictly ataxic symptoms, and the presence of a kyphos and of a considerable amount of paresis in the lower extremities, the diagnosis of tabes was rejected. The gradual onset of the disease, the rapid development of the lumbar deformity, the weakness of the lower extremities, the loss of the deep reflexes, and the strictly unilateral character of the sensory changes pointed to a lesion involving the lowest portion of the spinal axis. The diagnosis of a malignant neoplasm was made after the first examination. In deference, however, to the views of several colleagues, to the suspicion of tuberculosis years ago, and to the signs presented by the patient at the time of the examination at the hospital, and also in consideration of the marked kyphos present, the possibility of a lumbar Pott's disease was borne in mind. At the suggestion of the attending physician, the patient was suspended, and it was concluded to put him upon the iodides, nutritious diet, etc., and other appropriate treatment for a period of two weeks. While the patient was suspended, it was noted that the kyphos was not corrected and that the patient could hardly move his legs and thighs. During the period allowed the symptoms showed no improvement, and on November 3d I urged the patient's removal to the surgical ward for operation by Dr. Gerster.

The symptoms had not been altered, except that the weakness of the legs had slightly increased, but the areas of disturbed sensation remained practically the same. It was at this time a little doubtful whether the trouble was entirely restricted to the cauda equina, or whether the lumbar enlargement had been partially involved. The conclusions reached were that the neoplasm within the vertebral canal pressed upon the lowest spinal strands, those connected with the first, second, and third sacral segments. It was probable that the neoplasm arose from the inner surface of the bone pressing upon the left half of the cauda, but that it had gradually extended across the median line to the right. It was evident that the disease was steadily progressing, and the appearance of the kyphos denoted involvement of the body of the vertebra. The mercurial and iodide treatment to which the patient had been subjected in the medical wards had been of no avail; the possibility of a gummatous affection was dismissed, so that the diagnosis was narrowed down to a tuberculous or other malignant neoplasm. If tuberculous, there was every reason to suppose that the process was strictly localized, and I did not, therefore, allow this possibility to deter me from urging operative interference.

At my suggestion, Dr. Gerster, on November 10, 1899, undertook to do a laminectomy of the second and third lumbar vertebræ. I quote from the surgeon's record of the operation:

"Longitudinal incision from 12 D to 4 L. As soon as lamina of the third lumbar was removed, nodular, elastic, pale, somewhat gelatinous masses were seen to occupy the space between the laminæ of the second lumbar and fourth lumbar vertebræ. Puncture gave no result, proving the masses were solid. The spine of the third lumbar vertebra was movable and detached from the lamina. As soon as this was removed it became evident that the entire posterior portion of the third lumbar vertebra had been invaded by a new growth, which had disrupted the cohesion between the spine and the laminæ. The loose portion of the lamina of the third lumbar vertebra was removed by forceps and scissors, when the semi-globular tumor mass was exposed in its full extent. To ascertain whether the neoplasm extended up the canal, the spinous process and the lamina of the second lumbar vertebra were also removed, and it was shown that the tumor extended only to the lower margin of this vertebra. The tumor was removed, and above the normal and glistening dura was clearly seen. The cauda equina under the tumor had evidently been much compressed and appeared attenuated. The wound was drained with gauze, and most of it closed with button sutures. The patient made a good recovery from the operation."

Sections of the tumor, prepared for me by Dr. A. Wiener, show it to be a small-celled fibro-sarcoma.

The first sensory tests were made two hours after the operation, and at that time seemed to be about the same as before the operation, except that on the right buttock the area of anæsthesia was more extensive. Three days after the operation, on the 13th, sensation in the legs seemed improved. The patient could feel stimuli, but had some difficulty in locating the point at which he was touched. Since the day of operation the patient has been improving steadily, but he is still confined to his bed. The wound has been allowed to granulate slowly, for the purpose of thwarting the recurrence of the new growth.

The history of the case has been rather uneventful, the patient slowly regaining power in both lower extremities, having full control over the vesical and rectal reflexes, but exhibiting more marked disturbance of sensation.[1] The extension of the areas of anæsthesia directly after operation must be attributed to hemorrhage or some other slight accident during the operation. At the present time there is only a slight anæsthesia to touch and to pain on the soles and dorsal margins of each foot, and on the posterior aspect of each thigh and leg, the disturbance being greater on the left side than on the right. Both knee jerks are absent, and an electrical examination proved that the responses were diminished, but not distinctly altered in any of the thigh and leg muscles or nerves.

Although this patient has not yet fully recovered his health, the improvement is so marked as to lead to the hope of a temporary recovery. The resemblance to the first case was so striking that I felt justified in reporting it; for we can claim in this, as in the case of the first patient, that life has been prolonged by the operation. Surgical interference was surely warranted, and if any error in judgment has been made it was in the length of time the operation was delayed. If we had not deferred to the fear that the disease was, after all, tuberculous, I doubt whether the invasion of the bone would have been as complete, and we could have been more certain of radical enucleation of the tumor. While Dr. Gerster removed as much as could be seen of the malignant mass, it is possible that some of the new growth remained behind, and the danger of relapse is, therefore, so much the greater.

graphs of Schlesinger[1] and of Bruns[2] have left little to be said on the subject of spinal tumors, but it may not be amiss to refer briefly to the lessons taught by the experience here recorded. Bruns' opinion, that the diagnosis of an intravertebral tumor can be made only by a fortunate combination of circumstances, may hold good in many instances; more often the examination has not been searching enough. In my first case a chronic neuralgia was diagnosticated, in the second a tabes dorsalis. In the first case the error was pardonable, for the sensory changes were so slight that I would not have ventured to attach much importance to them, if the disturbances in sensation had not tallied very accurately with the area which was painful on pressure, and pressure exerted over the area produced pain corresponding in every particular to that felt spontaneously by the patient. In the second case the areas of anæsthesia were also distinct and peculiarly limited to the sacral distribution. The unilateral disturbance of sensation in one-half of the perineum, scrotum, and penis is surprising, in view of the large size of the tumor; but evidently it must, for mechanical reasons, have exerted far greater pressure upon the left than upon the right half of the cauda equina. In both cases the question arose whether the symptoms were due solely to pressure upon the cauda equina, or whether the lumbar enlargement was the site of the trouble independently of, or in association with, the cauda equina. The restriction of objective sensory disturbances to the region supplied by the sacral plexus, the bilateral distribution of the pain, the absence of marked vesical and rectal symptoms, the relatively slight paralysis, pointed to the cauda equina and not to the lumbar enlargement. The question was practically settled by the discovery in each case of an area painful on percussion below the level of the second lumbar vertebra. However secure we may feel in our present knowledge of segmental function, it will surely be wiser to urge operation at or near the site of a kyphos, or over the painful area on the spine and from there upward or downward, than to disregard such palpable evidence of trouble and to trust in refinements of diagnosis. In both cases the method was adopted with entirely satisfactory results.

Segmental diagnosis[3] has been carried to such a degree of perfection that the more difficult question is not, Where is the lesion? but What is the nature of the lesion? Do the symptoms warrant a diagnosis of tumor in a given case? Pain and other sensory or motor symptoms, strictly localized, unilateral or bilateral, but progressive, and bearing for a long time the characteristic marks of root symptoms, followed possibly by symptoms of an advancing invasion of the cord substance, should suggest the probability of intravertebral neoplasm. If extra-spinal, the sensory symptoms will predominate for a long period of time; but whether extra- or intradural, it is not easy to decide; except that if the neoplasm is intradural, cord symptoms will be added earlier to those pointing to root involvement. In both my cases I predicted extradural growths, because unilateral symptoms persisted for a great while, and in the second case because of the rapid invasion of the spinal column while the sensory symptoms remained unilateral.

Upon the nature of the growth in either case I did not care to speculate, for an experience[4] reported thirteen years ago taught me that solitary tubercles may occur in the spinal cord of persons who are apparently in excellent health, and who had not presented tuberculous signs in any other organ. In the first patient sarcoma was probable; in the second, the history of tuberculous disease suggested the possibility of spinal caries or of solitary tubercle; the new growth was, however, distinctly sarcomatous. If one bears the entire progress of the disease in mind, there are, after all, few chronic spinal processes that take the slow yet steadily progressive course so typical of intravertebral neoplasm.

Whenever there is a strong suspicion of extra-spinal neoplasm, and a possibility of reaching the site of a supposed tumor, an exploratory operation should be attempted, and at as early a stage as possible. I am thoroughly opposed to unwarranted operations, as when there is evidence of complete destruction and involvement of the cord; but in this matter I would prefer to take sides with Horsley and Starr than to adopt the ultra-conservative views from which even Bruns could not wholly escape. An exploratory laminectomy, if properly done, is comparatively harmless, particularly in the dorsal and lumbar regions; and, fortunately, a large number of spinal neoplasms occur in these regions. The removal of several lumbar laminæ does not interfere with the stability of the vertebral column. In my first case, even if the tumor had not been found, the patient would not have been made worse by the operation; and this, I doubt not, would be true of many other cases. The second patient would have had better chances of rapid recovery if the operation had been done a fortnight earlier, when the idea was first mooted. In the presence of malignant disease prompt action is the most conservative. The report submitted herewith should give some support to that view.

PUERPERAL INSANITY.[1]

By WILLIAM HIRSCH, M.D.,

NEW YORK.

Since the earliest times in the history of medicine the relation of child-bearing to insanity has interested physicians. The literature which exists on this subject has become so voluminous that it hardly can be overlooked to-day. If in spite of this I take the liberty of bringing this subject before you, it is not because I think that I can add anything to the facts collected, but rather on account of the great differences of opinion which exist among physicians on the subject. I feel the more justified in doing so, as these differences do not consist entirely of academical and theoretical questions, but have an important bearing on the treatment and general management of individual cases.

Since the doctrine as enunciated by Hippocrates, it has been a generally accepted theory that all the different stages belonging to the process of gestation are apt to produce certain forms of mental disease, which, according to this theory, were classified as psychoses of pregnancy, psychoses of puerperium, and psychoses of lactation. When I speak of puerperal psychoses, I wish to be understood as comprising all these three categories under the general term. A great many theories have been advanced as to the pathological relation between the uterus during this period and the psychoses. Hippocrates laid great stress on the manner in which the milk entered the breasts, and held this process responsible for the production of the mental disease. According to him the retention of the lochia post partum produced a maniacal condition. Since the times of Hippocrates this view, though under various modifications, has prevailed, that the entire process of gestation in all its different phases produced certain chemical changes in the female body, which under favorable circumstances may affect the brain and produce a mental disorder. It is not my intention to give you a history of the various theories and views regarding this subject. I wish to discuss only certain questions, and especially those which are of practical importance, which must necessarily influence us in the treatment and management of the patient.

[1] Read before the Metropolitan Medical Society, January 24, 1899.

The principal question of course, in which all our investigations must culminate, is the rôle which the process of gestation plays in the production of psychoses. This point is of vital importance in the treatment of our patients. Take, for instance, a woman who develops a severe psychosis, say during the third month of pregnancy. Shall we allow her to go to term or not? I think it is evident that if we are convinced that pregnancy as such has produced the mental disease, we could not expect to cure the latter while the cause not only persists, but increases for the next six months with the further progress of pregnancy. According to the fundamental principle of the practice of medicine, it would be our duty to remove the cause of the disease—to empty the uterus. In order to throw some light on this important question it is necessary to discuss several points. The first would be: Does there exist a certain form of mental disease which is clinically so characteristic that we could make the diagnosis of a puerperal psychosis merely from the psychopathic symptoms, as for instance we can diagnosticate an alcohol psychosis or epileptic insanity merely from the clinical aspects? This has been claimed by only a few psychiatrists, as for instance Fürstner, who in the year 1875 published a few cases under the name of "puerperal insanity," of which he claimed that they formed a special disease which was clinically well defined and different from any other form of insanity. Whether Fürstner has kept up this view until to-day I do not know. His new disease, however, seems not to have been accepted by other psychiatrists, and I think that nobody believes to-day in the existence of a specific puerperal psychosis.

If, therefore, the process of gestation plays any rôle at all in the production of insanity, it can be only that of an etiological factor like other etiological moments. The place which it occupies in etiology could be determined solely by experience and observation, and in order to determine this important question we have to refer to a valuable but equally dangerous medium of science—*i.e.*, statistics.

I do not intend to fatigue you with figures either from my own experience or from the observation of others. I only want to ask you to let me consider with you for a moment the manner in which statistics have been employed in this question, and what conclusions have been drawn from them. Most authors who have written on this subject have taken the entire number of all mental diseases among women which came under their observation, and then calculated the percentage of those cases which would go under one of the three categories of puerperal psychoses. In other words, any woman who was either pregnant or was in the puerperal stage, or who nursed a baby at the onset of the disease, counted as a puerperal psychosis. The higher the percentage of these cases was the more apparent was, according to the conclusion of these authors, the connection between the process of gestation and insanity. Some writers, as for instance Ripping, report that nearly twenty-two per cent. of all their female cases of insanity were puerperal psychoses. Now, are we justified in drawing such conclusions from these figures? I think that it would be a great mistake to do so. In my mind these figures do not prove more or less than the simple fact that of so and so many insane women such and such percentage happened to be in one of the stages of gestation. In order to decide the point in question it would be necessary to supplement these figures by others, as, for instance, what is, under normal conditions, the percentage of women who are in one of these stages? If we consider that one entire process of gestation, including the stages of pregnancy and lactation, takes nearly two years, and that in some countries the average woman has five or six children, it is evident that if these women should get a mental disease at all between the ages of twenty and forty years, they have more than fifty per cent. of chances to be classified as puerperal psychoses. It always remains to be proven that such a woman would not have acquired the disease just as well without her pregnancy.

While it is very difficult to obtain from statistics sufficient data to draw any reasonable conclusion regarding this subject, I think the figures themselves which have been reported by different authors may lead to quite an opposite verdict if they are looked at in a certain light. There are, for instance, very marked discrepancies between their various reports. As I said, Ripping reports 21.6 per cent. of puerperal psychoses, while others have totally different figures. A recent publication from one of the largest private institutions in Germany has only 12.5 per cent. Now what is the reason for this discrepancy? This latter institution receives mostly patients of the higher classes, especially of the German and Russian aristocracy, while Ripping's report is from a public institution in which the patients belong to the lowest class of social life. Now what follows from this? That in the aristocracy the process of gestation is less apt to produce mental diseases than in the lower classes? If this were so, then the total percentage of insanity ought to be less also in the higher classes. But is this true? No, quite the contrary; there is much more insanity among the aristocracy than among the laboring classes. The only conclusion, therefore, which could reasonably be drawn from these figures is, that the women of the higher classes bear fewer children than those of the lower classes, which assumption corresponds, as you all know, to facts. Most women of the laboring classes between twenty and forty years of age are either pregnant or nursing a baby, while in the aristocracy women are much more careful in preventing conception, and nursing their own babies is quite a rarity. In an analogous way the reports of French authors show considerably lower figures in the percentage of puerperal psychoses for the simple reason that French women have fewer children. But is insanity a rarer occurrence among French than among German women? By no means. The percentage is, on the contrary, higher in France than in any other country. What do these figures prove, then? If anything, they show that the process of gestation plays quite a subordinate rôle in the etiology of mental disease.

Furthermore, if the different phases of child-bearing would really play such an important rôle in the production of psychoses, it would be reasonable to expect that in all these cases of so-called puerperal psychoses the other etiological factors should be less than in ordinary cases of insanity. The principal element in the etiology of mental disease is, as you all know, heredity. Now is there less heredity in these puerperal cases than in others? No; according to the reports which I have referred to, there is even a higher percentage of heredity in these cases. The recent report from the German institution mentioned gives heredity in sixty-six per cent. of these puerperal cases, which is even higher than one usually finds in insanity. In my own cases of mental diseases of all kinds I have found heredity as an etiological factor in only fifty-eight per cent.

If, furthermore, these twenty per cent. of all cases of female insanity should really be due to the influence of gestation, insanity should be much more frequent among women than among men. But this is not the case. All statistics show that there is very little difference in this respect between the two sexes; that if anything men are in the majority. It is true that there are certain etiological factors in men which play an inferior rôle in women, as for instance alcohol and syphilis, general paresis being comparatively rare among women. This, however, is balanced by other factors in women besides child-bearing, as for instance the menopause, etc., but it could never reach the enormous difference of twenty per cent.

While all these facts strongly indicate that there is nothing peculiar in the so-called puerperal insanity, I will not deny, on the other hand, that the process of gestation may in some cases play a more or less important rôle in etiology, and that for the sake of proper treatment we have to make the relation between this factor and the mental disease a subject of special consideration in each individual case.

Now let us consider under what circumstances and in what diseases any of the phases of gestation might be apt to influence our judgment of the cases regarding the prognosis, or to affect our method of treatment and the management of the patient. Any pregnant woman, of course, might as easily acquire a mental disease as any other woman. The prognosis of such disease is exactly the same as it would be under ordinary circumstances. It depends on the history of the case, heredity, general health, and the general classification. Still the question will always be asked by the laity as well as by physicians, whether such a woman should be allowed to go to term or whether her pregnancy should be terminated. After what I have said before, it is needless to assert again that it would be obviously absurd to perform an abortion in every case of pregnancy complicated by a mental disorder. On the other hand, however, this question must always be borne in mind, as under certain circumstances the uterus should be emptied. The most frequent of mental diseases is a simple melancholia. As long as such a patient is physically in a good condition, as long as her general nutrition is good, there is no reason why we should interfere with the process of nature. Such a patient should be treated like any other woman with melancholia—which treatment, of course, cannot be discussed here—and the further course of the disease might prove to be entirely independent of pregnancy. I have seen quite a number of patients who developed a melancholia during the earlier part of pregnancy, and who under proper treatment made a prompt recovery before the birth of the child. There is, however, a certain class of melancholic cases, especially in weak, anæmic women, in which we have to deal with a rapid loss of strength and flesh, and in which, even under ordinary circumstances, it is sometimes extremely difficult to keep up the general nutrition. If such a woman is rapidly losing weight, I should surely not allow her to go on with her pregnancy, but would have an abortion performed, of course under the greatest precautions as to shock and loss of blood. The same holds good for cases in which the patient has to be fed forcibly with the stomach tube. Melancholic patients sometimes have the delusion that they are too bad to eat, or they may want to starve themselves to death, or a hallucinatory voice may tell them: "You must not eat." In such cases it might be necessary to perform artificial feeding for some time, and as naturally under such circumstances the general nutrition can be kept up only with great difficulty, I would also terminate pregnancy in such a case. Another indication for surgical intervention would be extreme restlessness on the part of the patient, as we see it in cases of melancholia agitata or acute mania. Patients in this condition sometimes have to be forcibly restrained, and it is hardly necessary to point out the danger in which pregnancy might involve a woman under such circumstances.

There are some cases of hysteria in which the fear of having children is apt to produce a severe mental disorder. We sometimes see such women just at the border-line of insanity, and may be able by a surgical intervention to prevent the development of a severe psychosis. I must admit that just in these cases the question whether we shall interfere or not belongs to the most difficult problems in practice. On the one hand, we are averse to performing an abortion on any hysterical woman who does not want a child. On the other hand, we do not want a mental disease to develop, if we possess the means to prevent it. How we have to act in individual cases of this kind cannot possibly be described theoretically. Our decision must be based on personal experience, on psychological and psychiatrical knowledge. No rules can be laid down; every case has to be judged by itself. I have seen several cases of this kind during the last few years, in which I feel satisfied that the development of a severe mental disease has been prevented by an operation.

A question which we are frequently asked is, whether insanity during pregnancy has any direct bearing on the offspring. As in all questions, authorities differ. My personal opinion is, that the development of the child will not be influenced at all by such a disease during pregnancy, but that the development underlies the general law of heredity as under ordinary circumstances.

The puerperal state plays a more important etiological rôle than pregnancy in the production of insanity. There are certain mental diseases which come on during or within a limited period after delivery which are indeed intimately connected with this process. It is this class of cases which gave rise to the term "puerperal mania." This name has been retained all over the world, although it is generally admitted to-day that most of these cases do not show true mania at all. In order to reach a clear understanding of this class of disease, and to realize the true connection between it and the process of parturition, it is necessary to consider several types respectively.

We sometimes meet cases of transitory disturbances of consciousness during the process of parturition. They are most frequently produced by mental shock, excitement, fear, etc. They occur mostly in unmarried women, in whom the natural excitement is increased by shame and sorrow. The clinical aspect of these cases is that of psychical epilepsy. The patient becomes suddenly very excited and agitated. The face is flushed, the eyes are staring. Her actions are impulsive and inco-ordinated. She might in this condition commit any act of violence, attack her friends or kill her child. After this condition has lasted for one hour or several hours, the patient passes into a deep sleep as after genuine epilepsy, from which she awakens with total amnesia for the period of her excitement. In some cases of this kind the history of epileptic convulsions in previous life may reveal their true epileptic nature. These cases have, of course, a great medico-legal significance, many cases of infanticide being due to this disturbance of consciousness.

Another group of mental disturbances during or after parturition may be classified as toxic psychoses.

The clinical features of these cases consist of an acute delirium. Of course, I don't mean the ordinary fever delirium, but a certain psychopathic state, which is apt to occur during the course of various mental diseases. This delirium as a rule sets in quite abruptly, without any prodromic symptoms or after a very short period of mental depression. It is not dependent on temperature. The patient may have fever or the temperature might be perfectly normal. The atypical form and the rapid change of the symptoms are characteristic of this form of disease. From a dull and apathetic condition the patient suddenly passes into a state of restlessness and agitation. Hallucinations of one or more senses are always present. There is incoherence of thought and action. The entire programme of psychosensory and psychomotor symptoms is apt to occur without order or system. The prognosis depends largely on the physical condition of the patient. Cases in which the constitution is run down and the general nutrition bad may terminate fatally within a short time. Otherwise complete recovery will take place. The duration of this class of cases varies from a few days to several weeks. When they do not end in recovery by this time a secondary psychosis develops which may assume the clinical character of an ordinary melancholia or mania, or frequently the atypical form of mental disorder may develop which has been described by Kahlbaum as dysphrenia. The secondary psychosis may last for a number of months and then end in recovery or pass into a state of terminal dementia.

As far as the etiology of these cases is concerned it would be erroneous to assume that we must necessarily have a septic infection. Any inflammatory process in the body is apt to produce a toxic psychosis. Cases of acute delirium, such as I have described, have been observed after any infectious disease as well as after any local inflammatory process even as slight as an ordinary angina. Therefore cases of vaginitis, endometritis, salpingitis, or oöphoritis occurring post partum are just as apt to produce the psychosis as severe septicæmia.

Some authors maintain that uræmia, with or without eclampsia, produces a special kind of insanity. I myself, however, do not agree with this view. We see in these instances the same toxic delirium which is produced by other toxic agents; besides, we must bear in mind that albuminuria is a comparatively frequent symptom in cases of psychoses and does by no means necessarily indicate a nephritis. Albuminuria is in a good many instances the consequence of the psychosis rather than its cause.

Those cases of mental disturbance which are produced by excessive loss of blood, such as may occur in placenta prævia, have a very similar clinical aspect. Here also the psychosis begins with an acute delirium, which, however, has more the character of inanition psychoses. We have the typical asthenic delirium which we frequently see after a collapse; this condition, too, may end fatally or lead to recovery after a short time. The development of a secondary psychosis is not so frequent as it is after a toxic delirium. If it does set in, however, the prognosis is less favorable than in the toxic cases.

Finally we see, after cases of very difficult labor, mental disturbances which might be classified as traumatic psychoses. They do not differ, however, from cases which may occur after any other trauma or surgical operation. Mostly they are of the hysterical type, but may assume a more severe character, as acute dementia, etc.

In all these different varieties of psychoses during or after parturition, the etiological factors which I have mentioned—shock, intoxication, inanition, and trauma—must of course be looked at only as the exciting causes. As a rule we find, as in most mental diseases, certain predisposing causes, as heredity, degeneration, malnutrition, anæmia, etc. Although parturition plays an important etiological rôle in these cases in one sense, it is evident that all cases might also result from other causes connected with shock, loss of blood, intoxication, etc., so that we are not justified here either in speaking of a specific puerperal insanity.

So far as the treatment of these cases is concerned we must, of course, give our first attention to the underlying cause—for instance, any local inflammation of the sexual apparatus. In those cases which are the outcome of exhaustion, an energetical stimulation of the bodily strength is of the greatest importance. A sufficient amount of nourishment is absolutely necessary. If the patient refuses to eat and cannot be fed otherwise, we must employ the stomach tube at once and not wait until the loss of strength has advanced too far. Nutritive enemata are very valuable as a help in nutrition, if the patient takes some nourishment through the mouth, but they cannot be relied on exclusively. In cases of delirium after excessive loss of blood, an intravenous or intracellular infusion of a saline solution is indicated. In the endeavor to preserve the general strength it is of the utmost importance to combat the motor restlessness. The patient, of course, has to be kept in bed. Wet packs and warm baths have often, at least temporarily, a soothing effect. If fever is present, ice applications and cold sponge-baths are useful. If the starting-point of the restlessness lies in the psychomotor area, hypodermic injections of hyoscine or hyoscyamine are efficacious, while in psychosensory irritation opium should be given. In some cases which seem to be dependent upon congestive conditions hypodermic injections of ergotin are often beneficial. It is of the greatest importance in these cases to produce sleep. In fact sleep is just as important as nourishment; a long period of insomnia may very quickly exhaust the patient and lead to a fatal issue. If sleeplessness sets in, as it nearly always does, it is therefore indicated to administer hypnotic remedies in liberal doses. Trional and sulphonal may be given in doses of 2 gm. Another valuable hypnotic in cases of this kind is paraldehyde, which may be given in doses up to 8 gm., even 10 gm. As long as the delirium persists, mental impressions of all kinds must be forbidden. Ornaments and pictures should be removed from the room, which must be kept dark. It should be absolutely quiet. The nurse must be instructed not to speak to the patient unnecessarily. If other psychoses, as melancholia or mania, develop secondarily, they must of course be treated as under ordinary circumstances.

Finally we have to consider the relation which the process of lactation bears to mental diseases occurring during this period. Although the various statistics show that insanity occurs more frequently during this period than during pregnancy, I do not believe that the process as such has anything to do with the production of the psychosis. It is evident that all the weakening influences which child-bearing has on the nervous system are apt to show themselves during the first few months after delivery. If we consider the many cases of anæmia due to post-partum hemorrhage, the cases of exhaustion through difficult labor, the mental excitement of the young mother, which is frequently increased, especially in the lower classes, by anxiety about the future, etc., we surely cannot be surprised to find the average nervous system of women during the first few months after delivery of the child more disposed to mental and nervous diseases than under ordinary circumstances. The psychoses which are observed during this period have absolutely nothing specific in their clinical features. They are the same as might occur in any other woman at any other time. Their prognosis depends on the same factors and the treatment must be the same as under ordinary circumstances.

In concluding I may be allowed to summarize with a few words the important points of the relation of child-bearing to mental diseases:

1. A specific form of mental disease, which might be called puerperal insanity, does not exist. The different psychoses which are observed during one of the stages of gestation are the same as those we see in other patients.

2. Pregnancy may, under certain circumstances, be one of the etiological factors of insanity. Its etiological importance, however, is proven by neither statistics nor clinical observation. It is, therefore, not permissible to terminate pregnancy on account of a psychosis, unless there are special indications for such intervention.

3. During parturition we sometimes meet a transitory disturbance of consciousness, the clinical features of which resemble psychical epilepsy.

4. Psychoses which occur in connection with the act of parturition are produced (*a*) by trauma in cases of difficult labor; (*b*) by anæmia and exhaustion after severe hemorrhage; (*c*) by intoxication in septic cases or cases with local inflammations, or uræmia. The clinical symptoms of this group of psychoses consist of an acute delirium which either leads to recovery after a short time or passes into a secondary psychosis. All these cases may be produced by the same causes in the non-pregnant state. The clinical features have nothing specific in any way.

5. Lactation, as such, plays no rôle at all in the production of insanity. It is due to other circumstances that during the first few months after delivery women on the average are more predisposed to nervous and mental diseases than under ordinary conditions.

Therapeutic Hints.

Conjunctivitis.—In white staphylococcus forms irrigation may be practised with decinormal salt solution, or with the following:

℞ Borate of sodium	℥ iij
Chloride of sodium	℥ ss.
Cryst. carbolic acid	gr. xv.
Water	gal. I.

The frequency of the irrigation should be regulated by the accumulation of matter on the surface of the conjunctiva. The upper lid being everted and the irrigating bag being hung twelve inches above the plane of the patient's eye, the nozzle of the irrigator is held over the bridge of the patient's nose and the fluid allowed to run over the everted lid and the inferior retrotarsal surface into a mass of absorbent cotton held on the temple. This should be repeated every half an hour.—DUDLEY S. REYNOLDS, *Medical News*, October 28th.

Diabetes Mellitus.—J. M. Allen (*Journal of the American Medical Association*, October 28th) says: The combination which I have used with apparent benefit is as follows:

℞ Creosote	gtt. ⅓
Tinct. nux vomica	gtt. x.
Saw palmetto	ʒ i.
M.	

In saw palmetto we have something of a tonic as well as a stimulant to the mucous membrane, thereby lessening retrograde metamorphosis of this tissue. Basing my treatment on the philosophy of etiology and pathology as given, it is as follows: (1) Allow the patient to eat only such foods as can be digested by the stomach, giving the duodenum rest, and thereby preventing physiological hyperæmia. This continued for a time will reduce the hyperæmia to a point so small and feeble as not to be a source of irritation to the inflamed, etc., structures. (2) Use intestinal germicides, the value of which, in my experience, is in the order given: creosote, sulphocarbolate of zinc, hyposulphite of soda, eucalyptol, menthol, oil of cinnamon, sulphide of calcium, salol, betanaphthol, carbonate of guaiacol. I have found the pulvis hydrastis canadensis, combined with salol, efficient and more or less alterative to the mucous membrane. To control reflex reaction I use gr. $\frac{1}{15}$ to $\frac{1}{10}$ of morphine three times daily, or aqua chloroformi, a dessertspoonful three times daily. All of these patients suffer more or less from anæmia of the nerve centres; to prevents this I give gr. $\frac{1}{60}$ to $\frac{1}{40}$ of strychnine nitrate three times a day, or the equivalent amount of nux vomica. As a tonic I use either the bitter tonics or the phosphate of lime, or wine of the phospho-glycerate of lime (Chapteau); the ferruginous preparations and the cod-liver oils should be excluded.

For Cystitis, especially in its chronic form:

℞ Balsami canadens	20
Magn. calcin	27
Pulv. sapon.,	
Pulv. benzoes	āā q.s.

Ut f. pil. No. c. S. Four to six pills daily.

—MESNARD.

Toothache.—

℞ Cocaine	0.25
Chloroform	q.s.
Essence violet	5.0
Camphorated oil,	
Essence peppermint,	
Creosote	āā 2.0

℞ Creosote,	
Chloroform,	
Laudanum	āā 10
Tinct. benzoin	30

Goitre.—It has been my opinion for some years past that iodine alone was the essential medical remedy for the removal of such goitres as could be influenced by medicine, and with this idea in mind I have, during the last four years, treated three-fifths of my cases with iodine and two-fifths with the thyroid preparation, and have found in thirty thus treated that the patients who received the iodine improved more rapidly than the others, and during the last three months my patients have been taking iodine, only accompanied by tonics as required. Few of them can take iodine steadily for many weeks, without showing evidence of weakness; slight anæmia is likely to follow, with increased rapidity of the heart's action; often slight dyspnœa and headache with diminution of bodily weight. The prescription is as follows:

℞ Iodi (crystals)	gr. ij.
Pot. iodid	gr. iv.
Spir. vini rect	ʒ i.
Syr. simplicis	ʒ i.
Aquæ destill	℥ ij.

M. S. A teaspoonful in a wineglassful of water, one hour after each mealtime.

After about two weeks, sometimes from the beginning, an iron tonic is given; and if the patients are weakening rapidly, strychnine combined with calisaya and iron, the iodine being discontinued for a week or two at a time. After three weeks there is usually a perceptible difference in the size of the goitre. In six months many of the goitres disappear, others are reduced to from one-half to one-eighth their original size.—FREDERICK G. SCHAEFER (*Journal of the American Medical Association*, November 25th).

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, January 6, 1900.

NEEDED REFORMS IN OUR AMBULANCE SYSTEM.

OWING to the fact that of late the oft-time and much discussed question relative to New York's ambulance service and the seeming inhumanity of some of our hospitals in subjecting patients to apparently unnecessary transfers from one institution to another has received considerable attention at the hands of the daily press, it is time to look at the question in its practical bearings as to possible reform.

Of the various charges brought against the ambulance surgeon by the laity, impugning his capability as a physician and criticising his general conduct, we would suggest that the many complaints harbored by the public are the result not so much of wilful shortcomings of the young surgeon as the outcome of a system which is palpably inefficient. To expect that a man but recently graduated from a medical college, and having had at the best but six months' experience in practical medicine, should be capable at all times of rendering a diagnosis absolutely correct and permitting of no doubt, would savor of the miraculous. That he might, however, without injury to himself cultivate a little more of the "*savoir faire*," and likewise be appreciative of the fact that an ambulance surgeon does not of necessity constitute the pivotal point around which the rest of mankind ought to rotate in silent admiration, is a bit of advice which, if followed, might tend to make the relations between himself and the general public of a more genial nature.

Mistaken diagnoses have been, and probably will continue to be, made, and we much doubt if there be a single practitioner who during some time of his career has not been guilty of an error; "*errare humanum est.*"

When any doubt exists, however, be it ever so slight, it should be accorded the patient, for it were far better that one hundred cases not demanding treatment were taken to the hospital than that one case diagnosed "drunk" should be for hours locked in a cell, and that later examination should disclose a serious injury or illness.

By making this a rule the opportunity would be denied the daily press of presenting, as was recently the case, a table of cases in each of which "intoxication" had been the verdict, while subsequent examination revealed serious injury; though in so large a metropolis as New York, in which hundreds of ambulance calls are daily answered, the fact that seven errors have been committed during a period extending over eighteen months, should not be accounted sufficient to prejudice the public at large.

If those of our hospitals equipped with an ambulance service would descend from their throne and revise some of the existing rules and regulations, it would benefit both their reputation and the public's safety, and tend to obviate future criticism. As we have before remarked, it is absurd to exact from a novice that which can be the result only of experience. The ambulance surgeon of the present day, when summoned to a case, has no opportunity for calling a consultation, but has to rely solely upon his own knowledge. Would it not be better, as a furtherance toward preventing mistakes, to constitute his duties the closing ones of his hospital career instead of the opening ones? During a space of one and a half years much valuable experience should be gleaned.

Transferring of patients from one hospital to another, save where it can be accomplished without the shadow of a risk to the life and health of the patient, is an unjustifiable act, and, if done to further an ulterior purpose, becomes criminal. A low mortality rate is a result to be desired, but fair means should be employed to obtain it. Only a few days ago a coroner's jury had occasion to denounce this practice and censure the hospital authorities for permitting repeated transfers, which ultimately resulted in the death of the patient concerned. Citizens of Greater New York are as a whole but little interested in hospital statistics, and the fact that one institution can, at the end of the fiscal year, boast of a lower mortality rate than some other, is a matter of but little import to them. What the individual desires, who when ill has to seek hospital treatment, is the feeling of assurance that he will be accorded all the care and attention necessary to his health and comfort, irrespective of the hospital receiving him. The fact that a mortally injured or sick person dies after admission to a hospital is not going to diminish the standard or injure the reputation of the institution concerned one whit. Every person of even mediocre intelligence realizes that wonders cannot be performed at the present day.

Poverty has from time immemorial been deemed a crime, and frequently treated as such; but surely in so noble a profession as that of medicine, one calling perhaps for more arduous work and unrewarded self-sacrifice than any other, the lowliest and most humble of our brethren should not be subjected to indignities which would never fall to the lot of his brother more blessed with worldly goods.

The needed reforms in the present system are obvious enough. There should be no such thing as questioning the fact whether or not a given patient is a suitable one for any particular hospital. Every institution having an ambulance should take any and every case presenting itself. In case of accident every victim is a suitable one for every hospital professing to care for emergency cases. If there is doubt as to the seriousness of the injury, the patient should be taken to the hospital for necessary diagnosis and treated there until he recovers or dies.

THE TREATMENT OF PNEUMONIA.

To die or not to die? that is too often the question that the physician is asking himself under the professional mask of encouragement that he assumes at the bedside of pneumonia or any critical disease. The more he doubts the certain efficacy of any particular drug, the more sincere he believes himself to be. To have unlimited, exuberant faith in any line of treatment, and emphatically and hopefully to prognosticate a successful issue, is, he feels, akin to quackery. An honest skepticism is the only attitude that his own heart will allow him. If the toxic effects are greater than the body can combat the patient must die. If not so great, the body will wage its own war and the methods of treatment are but turns in the scale one way or the other.

Such is the solid, unenthusiastic, almost resigned tone of the honest discussions that follow the presentation of any line of treatment for serious diseases. We are sometimes almost tempted to think that the physician can be little more than an umpire to decide how the fight is waging, and that his prescriptions have as little effect on life and death as his bulletins; but this is a hypersensitive, over-conscientious, faint-hearted attitude to take. It might be pardoned in the laboratory student whose chemical symbols work out in exact equations, but it should never be the attitude of the hopeful practitioner. The experience that accompanies good theory and sound judgment is something too individual and intangible to be set down in print as a rule for other men, but the fact remains that the spirit of fight and the energy of action are as essential in combating disease as the application of statistical studies. Every inch counts. Every step must be fought with the spirit to win, not with the cold calculation of chances. It is the old, level-headed player in this game of life and death who knows how to play up to his man and score a point with a worn-out trick.

And, after all, knowledge unfolds but slowly. What we claim for science one day we relegate to empiricism the next, when we find that we had hit a half-truth at random. Therefore there is salvation in the faith that begets action.

From this point of view the optimistic attitude taken by Dr. A. H. Smith, of New York, in a recent paper on "The Treatment of Pneumonia in the Light of its Newer Pathology" (*Medical News*, December 16, 1899) is worthy of further comment. It is of little moment from the present standpoint whether the pathology as outlined by Dr. Smith will stand the tests of further histological and chemical investigation, for he makes the assertion that pneumonia is not an inflammation at all, but simply a process which permits of the development of bacteria, *i.e.*, a culture medium. Apart from this he says that by reason of the fact that the lungs possess a double circulation, the study of therapeutic agents intended to affect them has special points for consideration. Reasoning from these hypotheses he claims that rational therapeutic indications would be met most directly by the application of local and general anti-bacterial agents. Thus if local contact with germicides could be effected, some progress could be made in the treatment of the disease; and since the blood exudate found in the alveoli supplies the pabulum for the growth of bacteria, any agent that can modify that medium and render it unsuitable for the growth of micro-organisms would be the means of solving the problem of pneumonia therapy.

If given at the outset of the disease, Dr. Smith says that the evidence at hand in favor of the beneficial results of the use of calomel is sufficient to merit its continued use. Its action, he believes, is to prevent the growth of further bacteria and not to counteract the effects of bacterial toxins already formed. Calomel should be given early in the disease. Small continued doses are probably as efficient as large amounts. The opinions of Flint and Hare with reference to the beneficial action of large doses of quinine are quoted with approval. Inhalations of chloroform are believed to be of some benefit, inasmuch as they exercise, in laboratory experiments at least, a depressing effect on the growth of the pneumococcus. The gratifying experiences of a number of observers who have administered creosote by inhalation and by the stomach are quoted, and in the form of carbonate of creosote its use is warmly recommended. The salicylates, notably the salicylate of ammonium, is highly thought of, not only acting on the pneumonia but exercising a stimulating effect on the heart.

Dr. Smith's preferences may be summed up in his own words: "I have been searching for the best weapon against the pneumococcus. I have used all the drugs mentioned with the exception of large doses of quinine, which have seemed to me too slow in action and too disturbing to the stomach. At one time the salicylates were my preference, but I think that late in the disease they may be depressing to the heart, and they may often cause gastric irritation. I now prefer creosote. In my hands it has done good service and the testimony of many authorities is strongly in its favor. . . . As to accessory treatment the indications are, first, stimulation of the emunctories to carry off the poison as it forms; second, sustaining the vital powers and particularly the heart; third, relieving the pulmonary circulation by vaso-dilators and venesection; fourth, compensation for loss of respiratory surface, by inhalation of oxygen; fifth, reduction of excessive temperature by cold; and, sixth, relief of incidental symptoms."

BULLETS IN MODERN WARFARE.

The war in South Africa is affording unfortunately an ample and accurate test of the effects of bullets fired from a modern small-bore rifle, and the conclusions so far arrived at coincide in most respects with the opinions formed of the destructive nature of these weapons and of the character of the wounds produced by them, by our surgeons during the Cuban and Philippine wars. Naturally, however, knowledge on the matter will be very considerably amplified owing to the number of men engaged, to the accuracy of the Boers' shooting, and to the fact that their principal weapon is the rifle. The firearm used by the British is the Lee-Metford, and the bullet is termed Mark II. The Boers use the Mauser. The Lee-Metford bullet is rather longer than the Mauser, but its velocity is somewhat less, consequently the momentum of each is practically the same. It should be said that both these bullets are wholly mantled, and are consequently non-expansive.

Drs. Keith and Rigby contributed to *The Lancet* of December 2d a very complete and exhaustive article on the nature of the injuries inflicted by the Mauser bullet, by the Mark II., by the Mark IV., and by the Dum-dum bullets. Although the experiments were carried out on the cadaver the results detract little from their value viewed comparatively. After pointing out that there were three different types of bullet wounds met with, viz., flesh wounds, wounds in which bone is involved, and wounds in which the bullet has passed through a cavity with fluid contents, Drs. Keith and Rigby went on to compare the destructive qualities of the four bullets in the following manner: If the destructive power of the Mauser be taken as a unit, that of the British service Mark II. bullet is nearly twice and that of Mark IV. more than twice as great, and the Dum-dum probably four or five times that of the unit. They sum up thus: "We find that the destructive effect of the Mark II. bullet, the Mark IV. bullet, and the Dum-dum bullet stand to the Mauser in the ratio of 1.7, 2, and 5.4 to 1. But this result applies mostly to flesh wounds, the bone-destroying and explosive tendencies of all, and especially of the open-nosed bullet Mark IV., being unnecessarily great. One point of exceptional interest in regard to all these injuries is that neither the wound of entrance nor exit is any index to the amount of destruction wrought. The conclusions, therefore, to be drawn would seem to be these; that the covered bullet expelled from a modern small-bore, provided no vital part or bone is reached, is not nearly so deadly as one fired from the older type of rifle; that when a bone is struck there is always fearful shattering, the bone being invariably irretrievably injured; that the unmantled and open-nosed bullets are the most effective, so far as disabling is concerned, of any yet brought out, their effect both on bone and soft tissue being of a terribly destructive nature."

News of the Week.

Northwestern Medical and Surgical Society.—At the thirtieth annual meeting of the Northwestern Medical and Surgical Society the following officers were elected for the ensuing year: *President*, Dr. R. A. Murray; *Vice-President*, Dr. Frank Grauer; *Treasurer*, Dr. Robert H. Greene; *Secretary*, Dr. S. Henry Dessau.

New York State Sanatoria for Consumptives.—The committee appointed by the New York State board of health to study the question of State sanatoria is preparing a report in which it will recommend that a system of local institutions be established with one or more State institutions, which shall be maintained by a per capita tax on the locality from which each patient comes. The plan is said to be at variance with that outlined in the bill introduced in the legislature last winter at the request of the State Medical Association.

Obscure Disease.—The physicians of Madison Township, Pa., are puzzled over an obscure malady which has become prevalent in the community and has proved fatal after a brief illness. By some the disease is thought to be cerebro-spinal meningitis.

Measles is reported to be epidemic among the children at Newburg, N. Y. More than one hundred cases have been reported to the health officer, twenty-three new ones in one day. No deaths have been reported, and few adults are attacked.

The Medico-Legal Society.—At the annual dinner and election of officers of the Medico-Legal Society at the Hotel St. Andrew on December 20th, the following were elected: *President*, Mr. Clark Bell, of this city; *First Vice-President*, Dr. George L. Porter, of Connecticut; *Second Vice-President*, Dr. T. D. Crothers, of Connecticut.

Osteopaths in Georgia.—Governor Candler of Georgia has vetoed a bill passed recently by both houses of the general assembly, providing for the practice in that State of osteopathy. At the public hearing given by the governor before taking action on the bill, it was contended that osteopaths knew nothing of materia medica, while they would be given the right to prescribe medicine the same as any regular licensed physician should the bill become operative.

Hospital Ships in Japan.—It is stated in *The Hospital* that Japan possesses several specially equipped hospital ships for use in warfare. These have been provided under the supervision of the Japanese Red Cross Society, which joined the Geneva Convention many years ago. The ships were built in England, and in time of peace are used as passenger boats. The *Kosai-Maru*, equipped only last year, has a fine saloon, easily convertible into a ward. Arrangements have been made for special wards for the isolation of infectious cases, and a distinct sanitary service will be organized in case of war.

A Red Cross Swindler.—A man, calling himself a clergyman, has been convicted at Fairfield, Ill., of fraudulently receiving money orders, and sentenced to imprisonment for eighteen months. He operated by soliciting contributions from persons in Ohio, Indiana, and Illinois in the name of the American Red Cross. In the presence of the contributors, he would seemingly insert a money order for the amount contributed in a stamped envelope and mail it to Miss Clara Barton. What he really inserted, however, was simply a blank piece of paper, the money order being slipped into his pocket and subsequently cashed on a forged order.

The Composition of Cigarettes.—An analysis of various brands of cigarettes, both English and American, has just been concluded in the laboratory of *The Lancet*. Tests for opium, arsenic, and other alleged ingredients were made, but they were negative in their results in every instance. The only injurious substance found was tobacco. We wish *The Lancet* commission had enlarged the scope of its inquiry a little, in order to determine what it is that causes the peculiarly nauseating odor of these nasty cylinders.

Japanese Physicians for China.—The Chinese authorities have engaged a staff of Japanese medical men for service at Newchwang, where the plague prevails. The mission numbers fifteen physicians who are said to have had special training. At its head is Dr. Murata Shosei, a pupil of Kitasato.

Trying a Tuberculosis Cure.—It is reported that a trial of Crotte's alleged cure for pulmonary tuberculosis, an attempt to exploit which was made at the Columbus meeting of the American Medical Association, is being conducted at St. Luke's Hospital in this city. The principle of the treatment, so far as M. Crotte has announced it, is the saturating of the diseased portions of the lungs with formic aldehyde by means of cataphoresis.

An Anti-Tobacco Congress.—The second international congress against the abuse (which is here synonymous with "use") of tobacco will be held in Paris during the summer of 1900. The work of the congress will be divided into seven sections, dealing severally with (1) history, statistics, various methods of the employment of tobacco; (2) chemical and physiological researches on tobacco; (3) diseases caused by tobacco; (4) hygiene and sociological questions; (5) education as a means of restricting the use of tobacco; (6) the morality and criminality of tobacco users; (7) miscellaneous. Papers may be read in English, French, German, Spanish, Italian, or Russian. Those desiring to become members of the congress are requested to signify their intention to the president of the committee of organization, M. E. Decroix, 20 *bis*, rue Saint-Benoit, Paris. The subscription to the congress, which has been fixed at five francs, or one dollar, should be sent at the same time.

Conscience-Stricken Contributors to Hospitals.—A writer in *Tit-Bits* says that in many of the London hospitals there is a list kept, headed "Hospital Conscience Gifts." Anonymous donors will often contribute a sum stating that they do so as a kind of expiation of some error or misdoing on their part, and the money so contributed is entered on this list. One gentleman contributed £20 to the accident ward of a certain hospital, stating that he offered the money as he had an accident, for which he regarded himself responsible, upon his conscience. He had seen a brick one night in the middle of the road in which he lived, and had failed to remove it. In consequence of this a cyclist met with an accident by which he was severely injured. A fashionable nobleman, who some time ago accidentally caused the death of a gamekeeper while out shooting, not only provided for the man's wife and family, but yearly contributes £200 to the hospital to which the unfortunate man was conveyed. Thoughtless throwers-down of orange peel contributed in one year to one hospital alone over £500—their consciences burdened by the memory of that thoughtless act which often results in misery to others.

Danger from Samples of Medicine.—The coroner of Philadelphia, after having investigated the death of a child from ingestion of sample pills, has called the attention of the director of public safety to the danger attending the indiscriminate and careless distribution of patent medicines and nostrums, particularly headache powders.

Smallpox and Chickenpox.—No end of trouble has been caused in various parts of the country during the past year or two by confusion in the minds of various physicians between variola and varicella. The latest case of the sort was at Dixon, Ill., where numerous cases of smallpox occurred in the course of six weeks, but were all diagnosed as chickenpox, the mistake not being discovered until there had been nearly one hundred cases. Recently a mistake the other way was made by a physician on a train between Chicago and New York. He notified the conductor that there were two cases of smallpox aboard, and the conductor telegraphed the news ahead to Pittsburg. When the train arrived there it was held, and policemen would not permit any of the passengers to alight. The city physician examined the patients, two children, found they were ill with nothing more serious than chickenpox, and the train was released. The passenger who had caused the commotion by declaring the cases to be smallpox was a physician from Kansas, and fearing that the passengers would carry out their promise to make it pleasant for him the rest of the journey, he waited over for another train.

Philadelphia Pediatric Society.—At a stated meeting held December 12th, Dr. C. F. Judson exhibited a case of Erb's palsy in a girl aged about ten years, due to pressure by forceps during delivery; also a case of rotatory spasm in a colored child aged about two years, with evidences of rickets; and a case of left hemiplegia with aphasia in a child about three years old, in whom there had been a convulsion at the age of ten months with left hemiplegia, and another convulsion at the age of eighteen months with paralysis of the left side of the face. Dr. Judson also reported a case of cerebral diplegia in a child that presented tremor. Drs. F. T. Stewart and Alfred Hand, Jr., detailed the account of a case of dilatation of the colon in a child three years old, terminating fatally. Dr. J. Madison Taylor reported a fatal case of hemorrhagic purpura, occurring in a girl thirteen years old; also a case of scurvy resembling syphilitic hemiplegia; also a case of Hodgkin's disease in a boy aged seven years, and a case of arthritis deformans in a boy aged nine years. Dr. Alfred Hand, Jr., reported a case of multiple auto-vaccination.

College of Physicians of Philadelphia: Section on General Medicine.—At a stated meeting held December 11th, Dr. Alfred Stengel exhibited a case of anæmia with splenic enlargement, occurring in a child three years old, in which following or in conjunction with enterocolitis there developed profound anæmia with enlargement of the spleen. The hæmoglobin was diminished in greater degree than the red cells, and there was no leucocytosis. Dr. Stengel proposed the following classification of the anæmias in childhood with enlargement of the spleen: A, without leucocytosis: 1, primary (splenomegaly); 2, secondary (syphilis, rickets, tuberculosis, gastro-intestinal disorders). B, with leucocytosis: 1, primary (leukæmia); 2, secondary. Dr. J. A. Scott read a communication on "A Case of Mitral Stenosis," with exhibition of the specimen, in which he discussed at length etiology, pathology, and diagnosis. Dr. M. Howard Fussell read a paper on "The Position and Color of the Ring in Heller's Test for Albumin in the Urine," in which he pointed out that the color-ring due to biliary pigment, potassium iodide, and the like is at the junction of the nitric acid and the overlying urine, the white band of albumin a little above this line of junction, and the ring of urates some distance above the latter. Dr. Joseph Sailer read a paper entitled "Withdrawal of Liquids from the Diet of Diabetes Mellitus," in which he related that such withdrawal in a case under observation failed to afford any relief, but rather aggravated existing conditions, primarily of course the thirst, and especially also the secretion of urine and the elimination of sugar. Dr. H. D. Beyea read a paper entitled "An Ovarian Cyst Associated with Diabetes; Operation, followed by Disappearance." He referred also to a few other cases of like nature recorded in the literature, and expressed the opinion that some undetermined etiological relation must exist between the character of the tumor and the morbid symptoms.

Pathological Society of Philadelphia.—At a stated meeting held December 14th, Drs. G. E. de Schweinitz and J. D. Steele reported a case of melanotic sarcoma of the choroid and orbit, in which primary operation was followed by recurrence. The secondary operation was radical and quite extensive, but there has been no recurrence. Dr. J. A. Scott exhibited a specimen of syphilis of the liver, the organ being enlarged, multilobulated, and covered by a dense capsule, with much cicatricial contraction and deformity. The spleen also was much enlarged, and mould-like deposits were present upon several portions of the intestine. Sections disclosed marked interstitial hepatitis. Dr. L. N. Boston also exhibited a specimen of syphilis of the liver, the organ being rather diminished in size and the seat of numerous nodules, some large, some small. Sections in this instance also exhibited the histological appearances of interstitial hepatitis. Dr. A. A. Eshner exhibited a specimen of carcinoma of the œsophagus, from an elderly man who presented during life symptoms, and after death lesions, of tuberculosis. The lesion in the œsophagus was situated about three inches above the cardia, and its histological character was disclosed on microscopical examination. Drs. J. H. Jopson and A. A. Ghriskey reported a case of anthrax, and exhibited cultures of anthrax bacilli in various media, as well as cover-slip preparations. The patient had been a morocco finisher, who presented a lesion upon the forearm acquired by inoculation of a scratch-wound, and in which bacilli were found that on microscopical examination and on culture exhibited the characters of anthrax bacilli. Death occurred suddenly and unexpectedly, but an autopsy could not be secured. No other case of the disease was observed among those employed in the same factory.

Diphtheria in Philadelphia is so prevalent that a number of schools have been closed for purposes of disinfection. It is now proposed to disinfect with formaldehyde all of the schools during the Christmas holidays, in order to begin the new year with a clean bill of health; and it is hoped that with aid of the volunteer staff of medical inspectors infection in the schools will be kept at a minimum.

An International Congress on Malaria is to be organized by the Liverpool School of Tropical Diseases. It was this school that sent out the commission under Dr. Roland Ross to Sierra Leone last summer, the labors of which have added so materially to our knowledge of the malarial mosquito.

Post-Graduate Instruction in Moscow.—The medical faculty of the University of Moscow has decided to open a school for post-graduate instruction, in which clinical instruction in twelve subjects will be given. The material will come chiefly from the Catharine Hospital, but other public hospitals and clinics will also be drawn upon as occasion offers.

Orleans Parish (La.) Medical Society.—At the annual meeting of the Orleans Parish (La.) Medical Society, December 10th, the following officers were elected to serve during 1900: *President*, Dr. T. S. Dabney; *Vice-Presidents*, Drs. H. S. Magruder, H. B. Gessner, and E. J. Graner; *Secretary*, Dr. E. H. Walet; *Librarian*, Dr. S. P. Delaup; *Treasurer*, Dr. Maguire.

The Eastern Medical Society of the City of New York.—At the annual meeting of this society, held December 8th, the following officers were elected for the ensuing year: *President*, Dr. Abram Brothers; *First Vice-President*, Dr. J. Guttman; *Second Vice-President*, Dr. A. Hymanson; *Secretary*, Dr. R. Abrahams; *Treasurer*, Dr. J. Barsky.

The Japanese Navy Medical Services.—There are one hundred and seventy-one medical officers of the Japanese navy, whose rank is as follows: Inspectors-general, two; deputy inspectors-general, thirteen; deputy assistant inspectors-general, twenty-one; fleet surgeons, thirty-one; staff surgeons, sixty-three; surgeons, thirteen; assistant surgeons, twenty-six; deputy assistant surgeons, two. The pharmacists number fifteen.

The British Medical Association will hold its sixty-eighth annual meeting at Ipswich, from July 31 to August 3, 1900. The president will be Dr. W. A. Elliston, and the local secretary Dr. E. A. Barnes of Eye. The address in surgery will be delivered by Mr. Frederick Treves, that in medicine by Dr. Pye-Smith, and that in obstetrics by Dr. W. J. Smyly.

The address in surgery will doubtless deal with military practice if the Boer war is ended in time to permit Mr. Treves to return from South Africa to deliver it.

Professor Koch, it is announced, is now studying malaria in Batavia, but will soon go to New Guinea.

Dr. Alfred E. Thayer of this city has been elected professor of pathology and bacteriology in the West Virginia University at Morgantown.

Berks County (Pa.) Medical Society.—At a stated meeting held at Reading on December 12th, Dr. John M. Bertolet read a paper on "Witch Doctors and Their Deceptions."

Bequests to Hospitals.—By the will of Mrs. Elizabeth C. Judd, widow of Colonel Henry B. Judd, of Wilmington, Del., $5,000 is bequeathed to St. Luke's Hospital, New York, and $500 to the Delaware Hospital of Wilmington.

Transactions of the Twelfth International Medical Congress.—The Russian government has made an appropriation of 9,200 rubles to cover the expense of publication and distribution of the volumes of Transactions of the Moscow Congress, which are now in press.

Help for Struggling Young Physicians.—A physician of St. Petersburg, Dr. G. I. Arkhangelsky, who died last summer, left nearly his entire fortune (about $12,000) to the Society for the Protection of Public Health, in order to establish a fund for the assistance of young physicians in the first years of their practice.

A Contribution to the Appendicitis Question.—In a letter to *The Medical Press and Circular* of recent date, Dr. Keen, of Philadelphia, mentions several of the most insistent advocates of instant operation in every case of appendicitis, and makes the surprising statement concerning them that, while they advocate this plan in theory, they do not practise it in fact.

An International Congress on Tuberculosis.—At a recent meeting of the Council of the British Association for the prevention of consumption, it was resolved to call a preliminary meeting of prominent individuals and representatives of institutions for the purpose of making arrangements for the Internal Congress on Tuberculosis, which is to be held in London in the spring of 1901, under the presidency of the Prince of Wales.

An International Health Conference.—The Italian Foreign Office has sent a note to the various powers which were represented at the International Hygienic Conference held in 1897 at Venice, inviting them to give their opinion as to the advisability of convening another meeting of the same kind to take measures, on an international scale, for the defence of Europe against the plague.

The Osiris Prize.—A triennial prize of the value of about $20,000 has been established by M. Osiris, of Paris, through the French Institute, for the most notable work published or discovery announced during the preceding three years, which shall be of benefit to humanity. Special reference is made to medical discoveries.

Doctors Mulcted.—A jury at York, Pa., on December 12th, awarded the plaintiff $1,000 damages against Drs. Vaillic and John A. Hawkins in an action to recover for alleged negligent treatment of a broken leg. It was charged that the leg was so tightly bandaged as to become gangrenous, and require amputation.

Camden (N. J.) District Medical Society.—At a stated meeting held on December 12th, reports were made as follows: Practice of medicine, Drs. E. L. B. Godfrey, J. R. Stevenson, W. R. Powell; health-conditions of Camden in respect to malaria and typhoid fever, Dr. E. L. B. Godfrey; contagious disease in Camden, Dr. J. F. Leavitt; gynæcology, Drs. H. H. Sherk, H. F. Palm, J. F. Leavitt; Surgery, Drs. Alexander McAllister, E. A. Y. Schellinger, Paul M. Mecray.

Philadelphia Neurological Society.—At a stated meeting held December 18th Dr. Wharton Sinkler exhibited a case of acute anterior poliomyelitis in a young man aged eighteen years, in whom the symptoms appeared after bathing for a long time in the open air. There was at first myalgic pain with loss of power in both lower extremities, followed by improvement almost to normal on one side, with persistent flaccid paralysis, loss of reflexes, and degenerative reactions in the other side, and without sensory derangement. The expulsive function of the bladder was at first impaired. Dr. James Hendrie Lloyd exhibited a case of hysterical choreiform movement in a girl aged about nineteen years, who presented rhythmic beating of the left hand against the thigh, and in the sitting posture also a distinct and asynchronous rhythmic lateral movement of the corresponding thigh. Other hysterical stigmata had not been detected. Restraint of the movement in the affected arm was attended with appearance of a similar movement in the opposite member. Dr. Charles K. Mills reported a case of unilateral progressively ascending paralysis, probably representing a new form of degenerative disease. Dr. Mills was inclined to consider the case one of unilateral amyotrophic lateral sclerosis, while Dr. Sinkler, who also had seen it, thought it might be due to disease of the posterior roots in their passage through the intervertebral orifices. Drs. C. W. Burr and D. J. McCarthy reported a case of serous meningitis in a man who presented symptoms suggestive of typhoid fever, but without Widal reaction, diazo-reaction, and other distinctive phenomena. Cerebrospinal fever also was thought of, as this disease was prevalent at the time. Improvement and exacerbation followed alternately on several occasions, but death eventually took place in coma. Toward the close deafness set in suddenly. Post-mortem examination disclosed in addition to excess of cerebro-spinal fluid thickening of the ependyma of the ventricles and round-cell infiltration of the subjacent brain tissue.

Similar lesions were induced experimentally in cats by introduction into the cerebro-spinal cavity of dilute hydrochloric acid, urine, bacterial toxins, etc. Dr. Joseph Sailer reported a case of motor and sensory disturbance of obscure nature occurring in a man about thirty-one years old, who presented loss of painful and thermal sensibility and of motor power, and increased reflexes on one side of the body, with early recovery, leaving only loss of sexual power. The urine was free from albumin. The lesion was thought tentatively to consist in some disturbance at the level of the restiform bodies.

Dr. Bernard Sachs has been appointed on the visiting staff of the Manhattan State Hospital to fill the vacancy caused by the death of Dr. Charles Inslee Pardee.

Bequests to Hospitals.—By the will of the late Mr. Daniel S. Ford, of Boston, proprietor of *The Youth's Companion*, the Massachusetts General Hospital receives $7,000, the Boston City Hospital $6,000, and the Children's Aid Society and the Children's Hospital of Boston each $5,000.

An Ambulance Refused by the Boers.—A dispatch from Durban to the London *Times* says that the Transvaal government has refused to receive the ambulance organized by Mr. Sivewright, an ex-minister of Natal, and that it will now be offered to Natal. It is not likely, however, in view of the circumstances that the authorities will accept it. The medical corps attached to this ambulance was composed of Afrikander physicians studying at the University of Edinburgh, who sailed only recently for South Africa.

The Course of the Plague.—A case of what was undoubtedly the plague was discovered on December 12th in the person of the bookkeeper in a Chinese establishment in Honolulu. The council of state was immediately called in extraordinary session, and appropriated $25,000 for the use of the board of health in combating the disease. The Oriental quarter was at once quarantined, and no one was allowed to enter or leave this section without a permit from the board of health. Within twenty-four hours after the bookkeeper's case had been diagnosed as the bubonic plague five deaths had occurred, all from the plague. Fumigation plants and crematories were established at the four corners of the Oriental section, and the bodies of the dead were cremated. The transports *Warren*, *Centennial*, and *Newport* were in the harbor, but left in the course of the week, the first-named for Manila. The others reached San Francisco on December 27th, and were detained at quarantine.—In India a recrudescence of the epidemic is threatened. Ahmednuggur has suffered very badly from the plague, and is not yet free from it. Sholapur now has a severe epidemic. Bombay is thought to be in the beginning of another plague experience. Parts of the Satara district have been badly attacked. News from reliable sources in the Orient is to the effect that the disease is prevalent in China and also in Japan, and the officers at Manila have taken precautions to prevent the plague from getting a foothold there.—In Mauritius during December there were twenty new cases of plague in the island, and twelve deaths from the disease occurred during the same period.—A despatch from Manila, dated January 3d, states that the health officers have found a native having all the symptoms of bubonic plague in a house in the walled city, where two deaths which may have been due to plague have occurred. The patient has been isolated and every precaution has been taken to prevent a spread of the disease. The quarantine system in the Philippines has been placed under the direction of the Marine-Hospital service. There are already two quarantine plants in the islands, and some of the surgeons of the Marine-Hospital service are already on their way to Manila and are expected to arrive there within a short time.

Smallpox has broken out among the Indians in the Colville Reservation, Washington.

Beriberi has been epidemic among the Chinese population in Hong Kong during the past summer and autumn.

Suit against a Chicago Hospital.—A woman residing in Racine, Wis., has entered suit in the Cook County circuit court against the Presbyterian Hospital of Chicago for $100,000 damages. She alleges that she has been made an invalid for life by the mistake of a nurse in the institution, who gave her a dose of medicine intended for another patient. The hospital authorities admit that an error was made by one of the nurses, but declare that the medicine given by mistake was harmless.

A Hospital Offered to the City.—Negotiations are said to be in progress looking to the transfer of the Brooklyn Homœopathic Hospital, Dispensary, and Training-School for Nurses, in Cumberland Street, to the New York City authorities. The plan suggested is that the control should vest in the city along with the actual property and obligations of the institution, and that in return the city should agree to maintain it under the homœopathic system. The property is worth about $150,000 and there are obligations amounting to $60,000. The hospital was organized in 1852.

The Alleged Grave Robbery in New Haven.—A hearing in the case of Dr. Oliver T. Osborne, professor of materia medica and therapeutics in the Yale Medical School, on the charge of unlawfully disinterring a body, was held at New Haven on December 26th. The charge was of removing from its grave, without permit for an autopsy, the body of a negro girl, within a few hours after burial. The prosecution was instituted on complaint of some members of the family of the dead girl, who watched the grave and claimed to have witnessed the removal of the body. Dr. Osborne denied that there was any attempt at secresy in the steps that were taken to secure an autopsy. The evidence brought forward by the prosecution was of a contradictory nature, and at its conclusion Dr. Osborne was acquitted of the charge.

An Attempt to Check Suicides.—It is said that a bill will be introduced at the coming session of the legislature at the instance of the New York State

Medical Society to prohibit the sale of carbolic acid except upon a physician's prescription. It is estimated that in 60 per cent. of the suicides in this State during 1899 carbolic acid was the means employed.

Professor Ogston, of Aberdeen, has gone to South Africa. He was not sent by the British authorities, but went as a private individual to take advantage of the opportunities there offered for the study of military surgery.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending December 30, 1899. December 23d.—Surgeon H. E. Ames, order of December 20th modified, ordered to duty in connection with fitting out the *Kearsarge*, Newport News, Va. Assistant Surgeon E. J. Grow detached from the *Massachusetts* and ordered to the *Dixie*. December 27th.—Medical Inspector M. H. Simons ordered to Cleveland, Ohio, for recruiting duty.

A Hospital Interne Suspended.—A member of the medical house staff of Bellevue Hospital was recently suspended for three months by the commissioners of charities. The action was taken because, it was charged, the physician received money with which to buy delicacies for a patient. The commissioner has posted in all the city hospitals an order forbidding all employees of the department of public charities, including the members of the medical staff, to accept from a patient, or other inmate, any sum of money for any purposes whatever, except with the knowledge and consent of the superintendent of the institution in which the patient or inmate may be. Any infraction of this rule will, it is announced, be punishable by instant dismissal.

Famine in India.—A recent report from Calcutta states that nearly three million persons are receiving aid from the famine relief fund. The government is spending almost 200,000 rupees daily. It is estimated that the cost of the relief to the end of March will be 30,000,000 rupees. Reports from American missionaries are to the effect that the present famine in Western India promises to be far more distressing than even the famine of two years ago. The entire community in some places will be in distress. A severe drought has already begun in the Ahmednuggur district. In many places it is hard to get sufficient water to drink, and no rain can be expected until the middle of June. The early crops in the Ahmednuggur district were only from one-eighth to one-sixth of full ones, and the later crops are almost a total failure. In other districts the crops are small. Husbands are leaving their wives, and parents their children. Relief corps are being organized; some charity also is administered, but official relief, Mr. Hume says, never can meet the multitude of necessities.

Obituary Notes.—Dr. Gustavus S. Winston died at his home in this city on December 29th of apoplexy. He was born in New York in 1833, and was a graduate of the College of Physicians and Surgeons in the class of 1863. In the Civil War he was surgeon of the Eighth Regiment, and was captured and confined in Libby Prison, from which he escaped with the assistance of a friend of the family, living in Richmond. Dr. Winston was medical director of the Mutual Life Insurance Company for about twenty-five years, and a great part of the time was the chief director.

Dr. Elliott Coues, of Washington, died at the Johns Hopkins Hospital in Baltimore on Christmas day, from the effects of an operation performed some time ago. He was born in Portsmouth, N. H., in 1842, and was graduated from the medical department of the Columbian University in Washington in 1863. In 1862 he entered the United States army as a medical cadet, and two years later was promoted to assistant surgeon, which rank he held until his resignation in 1881. His special interest was in natural history, more particularly ornithology, and wherever his army duties called him he made exhaustive studies of the fauna and flora of the region. He held the chair of anatomy in the National Medical College, Washington, from 1877 to 1883, when he was appointed professor of biology in the Virginia Agricultural and Mechanical College. The range of Dr. Coues' literary life was very great. He was the author of thirty-seven volumes, and contributed over one thousand articles to various magazines and periodicals. He served six different scientific journals in editorial capacities, and his name was on the rolls of more than fifty foreign and American scientific societies. One of his most important labors in recent years was done on the Century Dictionary, to which, in seven years, he contributed forty thousand words and definitions in general biology, comparative anatomy, and all branches of zoölogy.

Dr. Thomas O'Callaghan, of Jersey City, died suddenly on December 27th while making a professional call on a patient. He was sixty-five years old, and was a graduate of the New York University Medical School in 1862. He had practised in Jersey City continuously ever since his graduation.

Dr. Frank Gruber, of Newark, N. J., died suddenly on December 30th while attending a patient. He was stricken with apoplexy as he sat down at the bedside of his patient, and he died within a few minutes. He was fifty-seven years old, and was born in Germany.

Dr. Lewis Armstrong died at Middletown, N. Y., on December 31st, aged eighty-one years. He had been prominent in medical and business circles in Orange County for many years.

Dr. Henry F. Gehring, of Chateaugay Lake, died at Malone, N. Y., December 30th. A few days before he performed a surgical operation, and in some way slightly scratched his finger. Symptoms of septic poisoning set in, quickly resulting in death. He was a graduate of Starling Medical College, Columbus, Ohio, in 1884.

Dr. Francis G. Bonynge, of Chicago, died at his home in that city on December 26th. He was a graduate of the University College in London in 1878, of the Royal College of Surgeons in Ireland in 1879, and of Kings and Queens College, Ireland, in 1880.

Dr. Wickliffe Smith, of Delphi, Ind., surgeon of the 161st Indiana regiment, was killed on December

29th, together with his Cuban boy, Francisco Sousa, three miles from Delphi, by a Wabash train. On account of the cold weather they were bundled up so they did not hear the train. Both were instantly killed. Dr. Smith was a graduate of the Medical College of Ohio in the class of 1874.

Dr. Irwin Fisher, of Harlingen, N. J., was found dead in his bed on the morning of December 31st, He was a graduate of the Medico-Chirurgical College of Philadelphia in the class of 1896. He was a member of the Somerset County Medical Society and of the New Jersey State Medical Society, and was the coroner of Somerset County.

Dr. Almira L. Fowler Breakspear died on Sunday at her home in West Orange, N. J. She was seventy-three years old, and was born at Cohocton, N. Y. She was graduated from the Jackson Academy, Jackson, Mich., and from the Woman's Medical College of Boston. She first practised medicine in this city, and moved to Orange in 1858.

Obituary.

SIR JAMES PAGET, BART., F.R.S., F.R.C.S., D.C.L., LL.D.

The death is announced in London of Sir James Paget, in his eighty-sixth year. He was born at Great Yarmouth, January 11, 1814. He was educated at St. Bartholomew's, became a member of the Royal College of Surgeons in 1836, and was elected a fellow of the same institution in 1843. In 1875 he was president of the Royal College of Surgeons, and from 1884 to 1895 was vice-chancellor of London University. He was created a baronet in August, 1871, in recognition of his many discoveries in surgery. In 1881 he was appointed a member of the royal commission to inquire into the condition of the London hospitals for smallpox and fever cases. At the jubilee, in 1882, in commemoration of the three hundredth anniversary of the founding of the University of Wurzburg, he was one of the foreign scientific celebrities who received honors.

He was also a corresponding member of the Institute of France and an honorary fellow of many universities and other institutions. For many years he had been consulting surgeon of St. Bartholomew's Hospital.

Sir James Paget was one of the most famous English surgeons of the century, and made many contributions to surgical knowledge. Among his best known literary works are the "Pathological Catalogue of the Museum of the College of Surgeons," "Report on the Results of the Use of the Microscope," published in 1842, and "Lectures on Surgical Pathology," published in 1853, 1863, and 1868. He was also an extensive contributor to the "Transactions" of the Royal Society, of which he was a fellow, and other learned institutions. Since 1863 he had been surgeon to the Prince of Wales, and since 1878 sergeant surgeon to Queen Victoria.

The Cuban Orphan Society of New York City has made an application to the State board of charities to approve of its incorporation. The objects of the society are to care and educate the orphan and destitute children of Cuba through the establishment of an institution in Cuba for that purpose.

Progress of Medical Science.

New York Medical Journal, December 30, 1899.

Some Practical Notes upon Diseases of the Rectum.—L. H. Adler, Jr., alludes to the natural reluctance of patients to undergo rectal examination, and then passes to consider some of the maladies of this region most commonly met with. Congenital malformation occurs once in eleven thousand births. He believes that in fistula the internal opening is to be found in most cases between the two sphincters, and not, as is commonly believed, higher in the rectum. As to operation in phthisical cases, his rule is, "If the lung trouble is active, no operation; otherwise, operate." For cases of fissure, opium should be avoided and iodoform used instead. He believes that constipation is greatly on the increase, the latter being due to modern ways of living, adulterated food-stuffs, and rapid eating with little exercise.

Diphtheria: Remarks on Clinical Diagnosis and Treatment.—H. B. Sheffield emphasizes the essential early clinical signs of the disease, contrasting the appearance of the pharynx in diphtheria with that presented in the varieties of amygdalitis, follicular, parenchymatous, herpetic, and necrotic. Not much definite information can be obtained from the condition of the submaxillary glands, except that diphtheria presents generally a greater enlargement, hardness, and tenderness of them. Albuminuria strongly suggests true diphtheria. A table of diagnostic signs between laryngeal diphtheria and non-diphtheritic membranous laryngitis is given. He uses antitoxin only in combination with other remedies, and gives formulæ of drugs which have served him well.

Tubercle Germs and Giant Cells in Human Tissue.—P. G. Bourland refers to the literature of the subject of tubercle bacilli in giant cells, and narrates his own findings. Several thousand specimens were examined, including material from lung, kidney, liver, spleen, lymph nodes, and granulations from a tuberculous knee joint. In only four instances (three in lung and one in liver) did he find the bacilli within the cells. The full microscopic findings in the four cases are given. Bourland believes that the relation between bacillus and cell is a variable one. It is not fixed by anything apparent in the light of our present knowledge. He describes his method of examination and gives a bibliography.

Diet in Typhoid Fever.—E. Speidel advocates a daily rectal irrigation with two quarts of decinormal salt solution, and its interstitial injection in cases in which for any reason the rectum is unavailable. Water should also be given internally with great freedom. For nutrition, buttermilk, sweet milk (prepared in various ways), milk with malt extract, unfermented grape juice, strained oyster or clam broth in commencing convalescence, and broiled steak are all commended. The patient should be allowed chewing-gum for a short period each day. Then follow various solids. The article contains several practical recipes for the palatable preparation of the various food-stuffs named.

Mastoiditis: The Importance of Early Surgical Treatment.—B. J. F. McCaw concludes a practical article as follows: (1) In threatened mastoid involvement and in the mild acute cases the conservative plan of treatment should be tried for at most a week or ten days unless dangerous symptoms arise. (2) Operative interference should be instituted (*a*) in acute cases where there is sagging of the postero-superior canal wall, (*b*) when the infection is of a virulent nature, and (*c*) in all cases complicating chronic otorrhœa.

The Surgical Treatment of Phthisis.—W. C. Wood states that there are four plans of surgical treatment to be considered: First, aspiration of cavities and direct medication; second, pneumonotomy or incision and drainage of cavities; third, pneumonectomy or excision of a tuberculous focus; fourth, obliteration of a cavity by causing collapse of the lung. He gives the technics of each of the methods enumerated.

Examination of the Urine in Epileptics.—E. G. Klein examined the urine in twenty-three cases as soon as possible after an epileptic seizure. Specific gravity ranged from 1.007 to 1.026; traces of albumin were present in fifteen of the cases; glucose was not found in any. Results are also given of analyses of the urine of the same patients some time after the attack had passed over.

An Arrangement of Gastric Instruments Devised to Facilitate the Physical Examination of the Stomach and Its Treatment.—C. S. Fischer describes and figures various tubes, siphons, and electric-light devices which he has found of service for the examination and treatment of patients with gastric troubles. Nothing essentially new as regards treatment is given.

Heroin in Affections of Respiratory Organs.—H. D. Fulton commends the use of heroin in acute and chronic bronchitis as well as in tuberculous cases. A solution for hypodermatic use may be made by the addition of a little acetic acid. Maximum doses cause gastric derangements similar to those of morphine. The remedy is often curative as well as alleviative.

The Medical News, December 30, 1899.

Splenectomy.—J. Wesley Bovée, in a review of this subject, says that the operation was probably first performed by Zanarelli, in 1549. The spleen is thought to be the source of origin of leucocytes and the graveyard of the red blood cells, though in its absence the lymphatic glands and bone-marrow assume its function. No characteristic symptoms follow splenectomy in children, while in the adult they are increased pulse rate, syncope, pallor, temperature above normal, weakness, loss of weight, anæmia, headache, drowsiness, voracity, thirst, diminished or increased urinary secretion, griping pain in the abdomen, and pain and tenderness of the long bones. Among the indications for splenectomy are enlargement of the organ, malignant disease, axial rotation, wandering spleen, cysts, chronic congestion, amyloid disease, and rupture. But the operation should never be done except under the most favorable circumstances, unless immediate death threatens. Variations from the normal blood conditions, and leucocythæmia, are most important complications. The diagnosis is generally simple. The mortality of this operation between 1885 and 1895 is reported as 20.68 per cent.

The Pathology and Treatment of White Swelling of the Knee.—A. B. Judson asserts that white swelling of the knee goes from bad to worse so long as the patient continues to subject the joint to the weight of the body when standing, and the severe traumatism attending walking and running. He arrests motion by means of a posterior upright which is worn day and night. The weight-bearing function is held in abeyance by the use of the ischiatic crutch, worn only when the patient is up. In undue flexion of the knee the fixative brace may be used.

A Brief Report of an Epidemic of Typhoid Fever in Worthville, N. C., during 1898.—Charles Hubbard reports the recent epidemic of this village to be in accordance with Osler's observation, "Outbreaks of typhoid fever are more likely to occur in extremely hot and dry seasons when the water-supply is very low." In the whole town there were sixty-three pure cases with a death rate of about ten per cent., besides several suspicious ones. Eighteen of the sixty-three were under twelve years of age.

Journal of the Amer. Med. Assoc., Dec. 30, 1899.

Splenic Anæmia, or "Banti's Disease," Complicated by Diabetes Mellitus.—In *The Medical News* of March 27, 1897, H. A. Hare reported a case of splenic anæmia with grave blood changes in a man aged twenty-four years. An examination revealed a great excess of lymphocytes, although the total number of leucocytes was about normal. The red cells varied from time to time from 1,000,000 to 2,800,000. The spleen was enormously enlarged. While under observation from 1895 to 1898 nothing abnormal was revealed by examination of the urine. Hare now further reports that the patient came to him in November, 1898, and was found to be passing thirty grains of sugar to the ounce. It was not possible to make a blood count, as the patient failed to return the next day. The author is unable to say whether there was any connection between the two diseases.

Some Phases of Intranasal Surgery.—G. V. Woolen, of Indianapolis, summarizes the reasons which should underlie the chief operative measures in the nares, as follows: (1) To restore nasal respiration and relieve disease of the respiratory tract; (2) to aid the drainage of the nose and its accessory cavities; (3) to remove pressure irritation, (4) to remove local hyperæsthetic tissues; (5) to render local medication possible and successful; (6) to remedy auditory disease; (7) to remedy voice difficulties; (8) to remove malignant disease. Woolen urges that much confusion could be avoided by a proper consideration of what should be regarded as a normal nose in each individual case, and of the distinction between a temporary and a permanent obstruction or lesion.

Procedure of Election in Certain Cases of Enlarged Prostate.—In this article James H. Dunn advocates suprapubic enucleation in certain selected cases of prostatic disease, namely, that class of cases—relatively not very large—with large obstruction but few complications and comparatively young and sound physique. He claims that in a relatively sound man, even of advanced years, especially if the urine be uninfected, a skilfully executed suprapubic cystotomy is not a procedure of much danger. He believes that in these selected cases a skilled technique will reduce the mortality of suprapubic prostatectomy very materially below ten per cent.

Do We Obey the Code of Ethics?—R. G. Eccles, of Brooklyn, holds that the code of ethics of the American Medical Association is perfect in every respect, except where it forbids the prescribing of patent medicines. In the changed condition of things patented medicines, such as chloroform, are ethical, while the secret remedies are no longer patented. These preparations, whether advertised exclusively among physicians or not, which the author would have placed under the ban.

The Work of the American Pharmaceutical Association in Relation to the Materia Medica of the Future.—In this address F. E. Stewart, of New York, calls the attention of the profession to the work of the

American Pharmaceutical Association, and as chairman of that committee asks that aid may be given to make the pharmacy of the future what it should be, viz., a branch of medical science.

Diagnosis of Intestinal Perforation by Means of Ether Inflation per Rectum.—E. M. Sutton, of Peoria, reports a practical application of this means of diagnosis in the case of a gunshot wound of the abdomen.

Boston Medical and Surgical Journal, Dec. 28, 1899.

Surgery of the Bile Passages, Especially of the Common Bile Duct.—W. S. Halsted reports a number of cases in which operations for the removal of gall stones in the common duct were followed by truly splendid results, in view of the desperately emaciated and enfeebled condition of the patients. Briefly summarized, the cases were the following: Dilatation of the first part of the duodenum caused by constricting adhesions, with an ulcer on the confines of the pylorus; primary carcinoma of the duodenal papilla and diverticulum Vateri; dynamic dilatation of the first portion of the duodenum and of the pyloric portion of the stomach, gall stones in gall bladder, hydrops vesicæ; common and cystic ducts reduced to fibrous cords, dilated hepatic duct and gall bladder; choledochotomy performed twice, gall bladder shrivelled at first operation with two stones in duct, large and distended at second operation when only one stone occupied common duct; dense adhesions containing a small abscess; renal pains resembling intestinal colic—adhesions were absorbed with great rapidity after perforation and extrusion of stone; stone in ampulla ulcerated through walls of common duct and through its duodenal coverings.

Unlooked-for Dystocia in Certain Multiparæ.—E. S. Boland says in résumé of his article that certain multiparæ, after one or more easy deliveries, lose the power of natural parturition; this is due to failure of the expelling forces in the uterus and abdominal walls. Artificial delivery is imperative in such cases as promptly as a diagnosis is established. Infant mortality is high in artificial delivery by the natural passages. The human female is very tolerant of aseptic mechanical genital injuries. The author ends with the query, Is suprapubic delivery justifiable in these cases when a positive diagnosis is established?

Extraperitoneal Nephro-Ureterectomy for Tuberculous Disease.—A case is described by Edgar Garceau, in which nephrectomy was performed for pyelonephritis on October 25, 1897. The ureter was not removed, but the tuberculous ureteral stump caused abscess formation, which on November 24th was drained and the ureter removed. In October, 1899, the patient was in excellent health and strong enough to do an exhausting day's work. There are slight bladder lesions, and a few pus cells have been found in the urine, but the immense improvement in the patient's condition fully justified the operation.

The Closure of Rents Implicating the Anal Sphincter.—A. T. Cabot describes his method of operation upon a ruptured perineum, calling attention to the importance of dissecting out and suturing the sphincter-ani muscle with buried stitches of catgut.

X-Ray Examinations for Life Insurance Companies.—Francis H. Williams considers that an examination with the fluorescent screen gives the most trustworthy and complete evidence of the normal or abnormal condition of the chest organs.

The Philadelphia Medical Journal, December 30, 1899.

A Case of Successful Suture of the Vas Deferens Divided in a Hernia Operation.—John B. Roberts accidentally divided the vas deferens, which had been thinned by the pressure of a large hernial mass. He united the divided ends by making a slit in the lower, inserting the upper into the lower, and then closing the slit and holding the parts together by sutures. The operation seemed to be successful, to judge from the fact that there was no atrophy of the testicle six months or more later.

Further Thoughts on the Silver-Nitrate Injections in the Treatment of Pulmonary Phthisis.—Thomas J. May injects ♏ v. of a five-per-cent. solution of silver nitrate over the course of the vagi in the neck in the treatment of pulmonary tuberculosis. The results in some cases have been encouraging.

A Case of Tetanus Successfully Treated with Antitetanic Serum.—E. B. Adams adds one more case to the list of those in which orrhotherapy has been employed with success in tetanus.

Grave Secondary Anæmia Simulating Progressive Pernicious Anæmia.—J. M. Da Costa describes a case of secondary anæmia supposed to be due to achylia gastrica.

On the Significance of Bovine Tuberculosis and Its Eradication and Prevention, in Canada.—By J. George Adami. See MEDICAL RECORD, vol. lvi., p. 423.

General and Local Infection by the Bacterium Coli, with Report of Cases.—By J. N. Hall. See MEDICAL RECORD, vol. lvi., p. 244.

An Obstetric Tricyclic Calendar.—William L. Kantor presents a device by means of which the probable date of labor may be calculated.

A New Pile Clamp.—Arthur E. Hertzler shows an illustration of a new instrument.

The Lancet, December 23, 1899.

The Treatment of Surgical Tuberculous Affections.—In the second of the Harveian lectures, W. Watson Cheyne discusses the question of tuberculous peritonitis which he finds in about five per cent. of tuberculous cases examined post mortem. It may be due to various tuberculous foci elsewhere, but the most frequent source is infection from intestinal ulceration. The majority of his operative cases were in women, while the majority of cases as found on the autopsy table were in men. Reference is made to pathology, symptomatology, and complications. About fifty per cent. are cured by operation. The rationale of cure may be that the removal of a large amount of fluid may lead to an outpouring of serum, possibly bactericidal. Even in dry peritonitis the irritation of abdominal section and the breaking up of adhesions lead to a similar outpouring.

Observations Bearing on the Question of Influence which is Exerted by the Agglutins in the Infected Organism.—A. E. Wright and G. Lamb call attention to the fact that the agglutins are now regarded as bacteriotrophic and anti-bacterial. Divergent views obtain, however, on the question as to how far they exert an influence in warding off a bacterial invasion and restraining the growth of bacteria already active. As the result of a series of experiments made at the Army Medical School at Netley, the authors conclude that the agglutins are inoperative *in vivo* because their experiments establish the fact (or go far toward so doing) that the micro-organisms which cultivate themselves in the organism are as a matter of fact cultivating themselves in the presence of agglutins. This question is capable of being resolved by a quantitative determination of the amount of agglutins in the organs in which the micro-organisms are cultivating themselves. The experiments are along this line.

Gangrene Complicated by Glycosuria.—C. S. Wallace analyzes twenty-five cases and concludes that true gangrene occurs in diabetic patients unaccompanied by such arterial disease as would itself produce the gangrene. Glycosuria may precede the gangrene, and may be not a contraindication, but an actual indication for operation. The latter should be done before sepsis has set in, and the limb should be removed as near the trunk as possible. Sepsis may produce a glycosuria, while a pre-existing glycosuria may be aggravated by gangrene. There is no positive evidence that neuritis produces a glycosuria comparable to that of gangrene. The condition of the arteries may be similar to that associated with chronic renal affections.

Involuntary Reduction of Dislocation of the Shoulder.—E. I. Day records the history of a case of dislocated shoulder in a woman in whom reduction was attempted without an anæsthetic. Severe pain compelled a postponement, and for the succeeding night she slept sitting up in a chair. During the night she gave a sudden start and felt something move at the joint with intense pain, but immediately after she felt all right. Examination the following morning showed that the bone was in its right position.

Infantile Hemiplegia Associated with Aphasia.—Ernest Hutchinson gives the history of a boy aged two years who as the result of a fall experienced paralysis of the right arm, leg, and lower part of face and tongue, with inability to speak. He did well under a treatment similar to that given adults in similar circumstances, but the aphasia had persisted when the patient was last seen.

Lactation in a Male Infant.—G. M. Blair reports the case of a boy with highly developed mammæ as large as a walnut. Pressure caused milk to exude. The external genitals were normal except that only one testicle appeared in the scrotum. The child's general condition was bad, and he suffered from vomiting and emaciation.

Removal of a Hat-Pin from the Stomach.—J. Halliwell reports the case of a woman aged sixty years who accidentally swallowed a hat-pin about four and a half inches long. It was removed by abdominal section four days after. Operative details and recovery were without unusual features.

A Review of Surgery during the Past Hundred Years.—The Bradshaw lecture by H. G. Howes.

The British Medical Journal, December 23, 1899.

A Case of Scurvy-Rickets in a Boy of Twelve Years.—Edmund Owen looks upon rachitis as the prescorbutic stage of scurvy, and says that when he is told an infant or a child is the subject of scurvy he does not need to be told that the patient is also rachitic. The term scurvy-rickets was applied to the disease by Cheadle, but the author thinks the second part may well be dropped, the affection being called simply scurvy. When hemorrhages have occurred beneath the periosteum or into the planes of other connective tissues, the disease is no longer rickets, but frankly scurvy. Scorbutus is very rare in children over three years old, for by that time a child develops a taste for fresh fruit which he usually finds some means to gratify. Scurvy-rickets is more common among the children of the rich than of the poor, for it is the well-to-do mother who feeds her child on the prepared foods, the poor woman finding such fatal luxuries beyond her means. Mr. Owen has seen one case, however, in which the disease occurred in an infant who had been fed upon fresh cow's milk diluted with large quantities of barley-water. Even scalding the nursery milk with the view of freeing it of pathogenic germs materially detracts from its value as a food for infants. When infants are hand-fed the diet should be changed from time to time, no one kind of artificial food being relied upon exclusively. Another reason why the children of the poor are less likely to become scorbutic is that they get a taste occasionally of the food of their elders, and this, while possibly physiologically wrong, is not altogether without its recommendation.

On Primary Resection of Gangrenous Intestine.—Arthur E. Barker discusses the line of action to be adopted in cases of gangrenous strangulated hernia: (1) To incise the gangrenous loop and establish a permanent artificial anus; (2) to perform the same operation but subsequently to resect the intestine, reestablish its continuity, and close the fecal fistula; (3) to perform primary enterectomy and obviate the necessity of an artificial anus. The author's experience leads him to regard the last-named as the best course to pursue when the patient is not too exhausted. When there has been stercoraceous vomiting the stomach should be thoroughly washed out, before operation, with warm brandy and water. The patient should be wrapped in flannel or wool and be kept warm during and after the operation. In the after-treatment Barker advises the hypodermic transfusion of a pint of saline solution twice a day. Nutritive enemata are to be given every four hours, alternating with hot-water enemata at equal intervals.

Case of Syphilitic Disease of the Heart and Liver: Sudden Death.—Percival M. May reports the case of a man thirty years old who died suddenly after having suffered from intense precordial pain and vomiting. At autopsy syphilitic lesions were found in the liver and in the septum ventriculorum and other parts of the heart. Primary infection had occurred ten years before.

A Case of Snake-Bite Treated by Dr. Calmette's Antivenene.—Arthur Beveridge reports the case of a man, twenty-six years old, who was bitten on the ankle by a cobra. When seen an hour later he was in collapse. The wound was incised and pure nitric acid was applied, and an injection of 10 c.c. of antivenene was given. Stimulants were also given. The man recovered.

A Case of Rupture of the Heart.—Allan Kalenburg reports the case of a woman, forty-five years old, who was going up a steep hill with a load of thirty pounds on her head. She struck her foot against a stone and, failing to recover her balance, fell to the ground and died almost immediately. At the autopsy the heart, which was fatty, was found to be ruptured.

Fracture of the Spine in the Lower Dorsal Region.—Noble Smith reports the case of a man twenty-two years old who was crushed under his horse and suffered a fracture of the spine. An operation was performed four years and a half later, the patient being then paralyzed in the lower limbs. The result of the operation was a partial restoration of the power to walk.

A Case of Compound Depressed Fracture of the Skull.—John D. Gimlette reports the case of a Chinese coolie who suffered a fracture of the skull by a falling piece of quartz. He was trephined ten days after the accident. At this time he had hemiplegia of the left side. Eleven days after the operation power began to return in the paralyzed limbs, and the man eventually recovered entirely.

A Case of Poisoning with Liquor Morphinæ Hydrochloridi; Recovery.—Horace C. Colman reports the case of a patient with pulmonary tuberculosis who took a little over a grain of morphine hydrochloride in rather less than twenty-four hours, and presented quite marked symptoms of poisoning. Much benefit was derived from inhalation of ammonia.

An Unusual Case of Blood-Poisoning.—J. M. Pearson reports a case of septic poisoning in a woman eight days after childbirth. There were no symptoms indicative of a uterine origin of the trouble, but the uterus was nevertheless curetted and some small shreds of placental tissue were removed.

An Adult Infested by Oxyurides for Over Twelve Years.—E. Hawkins reports a case of this nature, in which, after many remedies had been vainly tried, a cure was obtained by the administration of four grains of cascara sagrada every seventh night for several months.

The Pharmacopœia in Its Relation to Medical Men.—The second of a series of lectures on "Pharmacy and the British Pharmacopœia," delivered before the Society of Apothecaries of London by Nestor Tirard.

The Surgical Treatment of Tuberculous Diseases.—By W. Watson Cheyne. See Medical Record, vol. lvii., p. 25.

Medical Press and Circular, December 20, 1899.

Suppurative Mastitis in the Newly Born.—Francis A. Winder relates a series of four cases of suppuration in the breasts of children shortly after birth. Three were girls and one was a boy. Discussing the subject of lactation in children, he says that it may be seen in male as well as in female children, and that it generally occurs very soon after birth. The quantity secreted is very small and tends to disappear spontaneously; it never oozes from the nipple, and it takes some amount of squeezing to cause it to exude, but if it is "drawn" more is secreted to take its place. It is this "drawing" which causes the breasts to inflame. There is always a history of interference, squeezing, rubbing, pressing the breast, etc. And finally, it is frequently a unilateral phenomenon. It is more frequently seen in the first-born of families. As to treatment the writer says, "Foment and leave alone."

Recto-Vaginal Hæmatoma.—Arthur Giles reports a rare instance of recto-vaginal hæmatoma following normal labor. There was pain beginning in the abdomen and later on referred to the rectum as well. On the morning after delivery the perineum was bulging and hæmatoma was diagnosticated, the tumor being of the size of a fœtal head, the skin being almost gangrenous. After careful cleaning an incision two and a half inches long was made over the most prominent point, and fresh blood and clots were washed out. No bleeding points could be detected. The cavity was syringed out with warm iodine lotion (ʒ i. to O i.) and packed with strips of cyanide gauze. There seemed to be no adequate cause for the hæmatoma, which in this situation is rare. The indication here seems to be to incise and pack early, and not to temporize as in hæmatomas of some other situations.

Cases of Amenorrhœa Treated with a New Salt of Manganese.—Dr. Murrell relates the case of a nursemaid, unusually anæmic, presenting a condition of uncomplicated oligochromæmia. Five grains of citrate of manganese were given three times a day. The following month the patient menstruated for the first time in nine months. A second instance of amenorrhœa treated with prompt results is given. The citrate is soluble and has advantages over binoxide and permanganate.

The Surgical Treatment of Tuberculous Diseases.—By W. Watson Cheyne. See Medical Record, vol. lvii., p. 25.

Some Notes upon the Tuberculin Test.—By Edward O. Otis. See Medical Record, vol. lv., p. 690.

Berliner klinische Wochenschrift, December 11, 1899.

The Scientific Establishment of Organotherapy.—A. Loewy and P. F. Richter make an earnest plea for the rescue of organotherapy from the semi-charlatanry into which it has in certain respects fallen, and for its establishment upon a firm, scientific basis. They recall the over-confident promises of Brown-Séquard and his suggestion of the phrase "internal secretion," and note the scepticism with which the profession has come to regard many forms of organotherapy, but from a review of some of the more important contributions to medical literature and from their own experiments they show that it has a true scientific basis which, while it needs to be more carefully determined in many directions, yet offers the certainty of positive therapeutic results. The greater part of the article is occupied with a description of the effects of the administration of ovarian extract (oöphorin) upon the female organism, showing that while extirpation of the ovaries is regularly followed by atrophy of the uterus and various nervous and psychical disturbances, the use of oöphorin after operation will prevent the occurrence of most of these untoward manifestations. They also commend the use of the preparation in chlorosis, claiming that it improves the blood state and leads to a regulation of the menstrual function.

Acute Lead Poisoning.—W. Zinn reports the case of a woman of thirty-three years who took in the dark by mistake a spoonful of a mixture called "silver-polish," which was afterward shown to be mainly oxide of lead. Six hours later she began to have the symptoms of mild abdominal irritation, which continued with varying severity for nearly three weeks, when she was seen by the author. He found the usual signs and symptoms of acute lead poisoning. The patient was placed on the customary treatment, but it was some ten weeks before her symptoms had entirely subsided. A reference is made to similar cases previously reported.

Certain Further Aspects of the Treatment of Tuberculosis.—E. Klebs calls attention to the gastric disturbances of tuberculosis, stating that in cases of pure achylia gastrica thyroid atrophy is often present. He inclines to the belief that this atrophy is due to the influence of the toxin of the tubercle bacillus. He has employed in these cases the fresh thyroid juice with most excellent results. A second point mentioned is that of mixed infection and the possibility of utilizing this principle in therapeusis. The author relates the histories of two cases of tuberculosis treated with injection of a substance isolated from typhoid cases. Marked benefit was noted in both.

Treatment of Whooping-Cough with Antitussin.—Max Heim commends the use of this remedy, claiming that it lessens the number and severity of the paroxysms, loosens secretion, may confine the malady to the catarrhal stadium, and is free from injurious effects. The remedy is a salve to be applied externally.

The Influence of Oöphorin on Albuminous Metabolism.—From experiments on a castrated dog, A. Loewy concludes that the internal administration of oöphorin leads to an increase of metabolism, and that at the expense of the non-nitrogenous substances in the body.

Münchener med. Wochenschrift, December 12, 1899.

Contribution to the Pathology of Syphilis of the Brain and Spinal Cord.—Theodor Struppler says that although earlier authorities thought that syphilitic affections of the brain developed only during the later stages of the disease, it is now acknowledged that they may occur at any time during its course, from a few weeks to years after the primary infection, occasionally even before the eruption. In such cases the suggestion might sometimes be made that these manifestations are due to reinfection, the first infection having been unnoticed. The following conditions are possible for the formation of a cyst: circumscribed gummata, induration of brain tissue, encephalitis, syphilitic arteritis with thrombosis, and encephalomalacia. Circumscribed gummata in the central nervous system are found chiefly in the meninges or in the cerebral cortex; in the cranial nerves, central ganglia, and ventricles. Heubner believed that simple encephalitis and softening of the brain, not dependent on diseased blood-vessels or new growths, frequently accompany syphilis. Oftentimes an exact differential diagnosis between specific encephalitis and encephalomalacia cannot be made intra vitam. The youth of the patient and the lesions found at autopsy in other organs are most important factors in forming a diagnosis. According to the investigations of Lamy, all syphilitic affections of the spinal cord are divided into spinal meningitis, meningomyelitis, and syphilitic myelitis, all of them being of vascular origin.

Involvement of the Anterior Abdominal Wall in Carcinoma of the Stomach.—Rudolf Seggel reviews this subject, and says that often gastric carcinoma is without symptoms—at least those referable to the stomach itself. As in the case of gastric ulcer, so in cancer, direct extension to the anterior abdominal wall is unusual. According to Strümpell, the extension of carcinoma to neighboring organs is just as rare. Murchison, in a series of three hundred cases, found only twenty-five of gastric fistula through the abdominal wall, and of these only six were carcinomatous. Lange, in two hundred and ten cases of cancer of the stomach, reports only one perforation of the abdominal wall. Cases of perigastritic abscess, originating from gastric carcinoma resulting from ulcus ventriculi and opening through the abdominal wall, have been reported. Still another mode of infection of the abdominal wall is by means of metastases through the lymph channels.

Syphilis of the Aorta as the Cause of Aneurism.—The teaching that aortic aneurism has been the result of endarteritis or arteriosclerosis has largely obtained, but Arnold Heller brings forward many arguments in favor of syphilis as the most usual cause of this affection. Clinical statistics support this view, and the results of antiluetic treatment in cases of aneurism also favor it. The syphilitic origin seems especially clear in cases occurring in youth and early adult life. According to statistics, the proportion of cases of syphilitic origin to all cases of aneurism is as follows: Heller, eighty-five per cent.; Malmsten, eighty per cent.; Rasch, eighty-two per cent.; A. Fränkel, thirty-six per cent.; Welch, sixty-six per cent.; Etienne, sixty-nine per cent.; and Gerhardt, fifty-three per cent.

Indications for the Transplantation of Skin-Flaps Without Pedicle.—Reuter, in a discussion of the relative merits of the Krause and Thiersch methods of skin transplantation, shows that although Thiersch's method will undoubtedly hold the chief place in the future, that of Krause is most valuable when there is a special necessity for preserving the elasticity of the part. Its value depends more on the recognition of the indications for its application than on the technique. It is especially useful in cases in which there is little danger of infection or of insufficient nourishmnt of the parts and in cases of contracture of joints from scars. Reuter cites one case in a child in which the skin-flap applied to the knee grew proportionally with the part on which it was planted.

The Munich Law Concerning the Hygiene of Dwellings.—Biberfeld discusses the possible working of a statute which provides that, if an apartment or living-room is found to be in an unsanitary condition, the tenant can leave at any time without giving legal notice.

A New Fermentation Saccharometer.—Theodor Lohnstein describes and pictures an apparatus for determining the percentage of sugar, which can be used with undiluted urine. The saccharometer is patented in Germany.

A Bicycle Satchel for Physicians.—Arthur Mueller describes an obstetrical bag which can be readily attached to a bicycle.

Deutsche medicinische Wochenschrift, Dec. 14, 1899.

Cholecystotomy with Waterproof Drainage of the Gall Bladder.—Poppert describes a new procedure which he has adopted with excellent results in the operative treatment of gall stones. The danger of the methods hitherto in use in the treatment of the gall bladder, especially when the latter is small, has been that of leakage into the abdominal cavity with resultant peritonitis. The author, after the gall bladder has been emptied, inserts a catheter and sutures the walls of the viscus firmly around it. Experience has shown that these sutures will hold absolutely for from ten to fourteen days, by which time adhesions will have formed, removing all danger of leakage. The gall bladder is not sutured to the external wound, but is left in its normal position, while the abdominal wound is carefully tamponed around the catheter. When the latter is removed there will be a fistulous tract leading down to the gall bladder, but walled off from the peritoneal cavity. This soon closes by granulation.

Room Disinfection by Means of Formaldehyde.—M. Friedemann presents a series of tables showing the results of disinfection experiments with formaldehyde, two different forms of apparatus being employed. The results obtained were encouraging, though very resistant bacteria and spores were not employed in the experiments. The main objection was the villanous odor, which rendered the rooms uninhabitable for two or three days after the disinfection had been effected.

The Formation of Sugar from Albumin.—Ferdinand Blumenthal presents an elaborate review of the literature bearing upon this question, and comes to the conclusion that we have as yet no entirely satisfactory and unexceptionable theory of glycogen formation in the economy.

Vratch, December 4, 1899.

The Plague Epidemic at Kolobovka in 1899.—A. M. Levin gives the history of this epidemic occurring during the past summer at Kolobovka, a village of thirty-five hundred inhabitants in the Astrakhan province, Russia. The disease was of a malignant character, twenty-three out of the twenty-four cases terminating fatally. Of these twenty-three deaths eighteen occurred within the first three days of the disease. Prompt measures of inspection, isolation, and disinfection were instituted, and the epidemic lasted only about four weeks, the first patient falling ill on July 16th and the last one on August 9th. On August 11th and the following days all the inhabitants of the village, except forty, were inoculated with Haffkine's serum in doses of 3 c.c. for men, 2 c.c. for women, 1 c.c. for children of school age, and from $\frac{1}{10}$ to $\frac{1}{3}$ c.c. for children under ten years of age. No ill effects followed the injections, and this first experiment of inoculation of an entire community was counted a success.

Rupture of the Perineum in Coitus.—K. K. Skrobanski reports the case of a healthy peasant woman, twenty-two years of age, who suffered a rupture of the perineum during the first attempt at coitus on her wedding night. The tear was about 2 cm. in depth and did not involve the anus. The wound was washed out and tamponed with iodoform gauze. Four days later the wound was nearly healed and the patient was allowed to return home, but was cautioned not to permit coitus for some time. She did not return, and when hunted up a week later was found to have disregarded the injunction of abstinence, but with no evil results. The author reviews the literature of this accident, and finds records of twenty-two cases collected by Neugebauer.

The Penetration of Formaldehyde into Objects in the Disinfecting-Chamber.—M. G. Verbalovski gives in detail the results of several experiments made to determine the efficacy of the Kareëff disinfecting-chamber. He found that the formaldehyde would thoroughly disinfect the interior of mattresses, pillows, upholstered furniture, etc., without injury to the fabric.

Bulletin de l'Académie de Médecine, December 5, 1899.

Upon the Existence of Arsenic Normally in Animals and Its Localization in Certain Organs.—Armand Gautier, as the result of experimentation upon animals and man, has found arsenic to be normally present in appreciable amount in the cell nuclei of the thyroid and thymus glands, in the skin, and probably in the pituitary gland, but absent from all other tissues. This discovery may have an important bearing on the treatment of diseases due to troubles of the thyroid gland, and should also be taken into account by toxicologists. Arsenic found in organs other than those mentioned would indicate poisoning.

Prophylactic Treatment of Syphilis.—M. Fernet takes exception to the way in which the out-patient clinics for venereal diseases attached to certain hospitals in Paris are conducted, especially to the publicity and to the overcrowding. He also complains that many persons of means apply for gratuitous treatment, whereas the clinics should be reserved for the really poor. He, however, disapproves of Fournier's suggestion that the venereal service in hospitals be under the charge of physicians selected by competitive examination, thus creating a new specialty in hospital service, which he considers to be against the interests of science and of physicians.

The Treatment of Functional Epilepsy by the Bromide of Strontium.—J. V. Laborde has found that 10 to 12 gm. of this drug daily, in divided doses, is efficacious in epilepsy.

Meditsinskoe Obozrenie, December, 1899.

Osteomalacia in Women and Its Treatment.—V. V. Uspenski advises total castration in the treatment of osteomalacia. In cases of pregnancy the removal of uterus and ovaries may be effected through the vagina in the early months, but Porro's operation is to be resorted to in the later months. In the early period of pregnancy, when a radical operation is not consented to, the best treatment is to induce abortion and follow that with a course of phosphorus. All the other modes of treatment—by salt baths, mud baths, sulphur baths, the internal use of mineral waters, nourishing food, a change of residence, weaning of the child (if the woman is nursing), the use of cod-liver oil, quinine, iron, lime salts, etc.—are uncertain and find application only as succedanea to the treatment by phosphorus or operation.

The Sense of Hearing in the Insane.—V. E. Larionoff tested the hearing in twenty cases of mental disease, in twelve of which there were or had been at some time auditory hallucinations. Two patients had fairly good hearing, but the others were either entirely deaf in one ear or could hear the watch only on contact or at a distance of from one to six vershki. In nearly every case bone conduction was absent both for the watch and the tuning-fork; yet nearly all could distinguish tones fairly well. The author concludes from this that there is a special musical centre in the brain, and this conclusion, he says, is confirmed by the results of his physiological and anatomical investigations.

Normal Pregnancy and Childbirth after Operation for Ectopic Gestation.—The course of normal pregnancy following the operative treatment of a previous extra-uterine gestation is, according to A. N. Solovieff, unquestionably more favorable than after an expectant plan of treatment. He contends therefore that, immediately upon a diagnosis of ectopic pregnancy being made, we should remove the fœtal sac in order to avoid those dangers which arise from the existence at the same time of the products of an intra-uterine and an extra-uterine pregnancy. The author reports a case of his own and cites many from the literature in support of this view.

Syphilitic Cirrhosis of the Liver and Chyliform Ascites.—V. Poliakoff reports a case of syphilitic cirrhosis of the liver, occurring in a woman forty-eight years of age, which was accompanied by a transudation into the peritoneal cavity of a milky-white fluid. This fluid was not chylous, as analysis failed to show the presence of fat. The author has found three cases of a similar peritoneal effusion in the literature, each of which was associated with a cancerous affection of the peritoneum. In none of these cases could the cause of the peculiar color of the effused fluid be determined.

The Nails of the Human Hand.—P. A. Minakoff has made an exhaustive study of the nails of the hand, some of the results of which he regards as of medico-legal importance. Among other things he asserts that the nails of the right hand in a right-handed person are wider by from one-half to two millimetres than the corresponding nails on the left hand, while in left-handed persons the reverse obtains, and in the ambidextrous the nails are of equal size on the two hands.

The thickness of the nails diminishes progressively from the thumb to the little finger.

A Case of Ovariotomy in the Fifth Month of Pregnancy.—I. S. Batasheff reports this case, in which the operation was successfully performed without interruption to the pregnancy.

A New Culture Medium for Tubercle Bacilli.—O. I. Bronstein has obtained very satisfactory results with Hesse's culture medium, as described in the *Zeitschrift fur Hygiene*, xxxi., 3.

A Review of Insane Asylum Reports in Russia for 1897.—V. C. Serbski analyzes the reports of seventeen institutions in different parts of Russia.

Revue de Thérapeutique, December 1, 1899.

Treatment of Affections of the Prostate and Seminal Vesicles in Acute and Chronic Blennorrhagia.—Jules Janet gives an exposé of the signs which permit a diagnosis of prostatic and seminal-vesicle implications in acute and chronic gonorrhœa: First, we must distinguish purely congestive from infectious prostatitis. The former is apt to come on after abundant washings with permanganate of potassium, giving difficulty in urination, a sensation of weight in the rectum, which persists between the washings. It is distinguished from the infectious form by the second test glass of urine remaining clear or clearing up rapidly under the influence of washings, and secondly in that this condition of the prostate does not interfere with treatment and does not prevent the permanganate washings from having their usual rapid effect. In case of infectious prostatitis we find (1) that the second test glass remains turbid despite the washings, and that we find quite lively gonococci, when perhaps there are few or none at all in the drop taken from the meatus; (2) that the treatment by permanganate does not succeed, and that recurrences are noted at the least suspension of washings; (3) that massage of the prostate followed by a washing is all that is necessary to clear up the urine of the second glass. The author then describes the symptoms of affections of the prostate and vesicles in chronic gonorrhœa. The article is to be continued.

Beer Yeast in the Treatment of Gastro-Enteritis, Particularly of Infancy.—E. Thiercelin and A. Chevrey report the result of experiences during the epidemic of last summer in Paris. It is thought that the presence of yeast in the stomach and intestines interferes with the development of germs and diminishes gastro-intestinal fermentation, or that its association with the gastro-intestinal germs determines a diminution of the virulence of the latter by a phenomenon of symbiosis analogous to but opposite to that which is produced in microbic associations when the virulence of the germs is great. In all the observations there was a rapid effect produced upon the diarrhœa. Levurin, which is looked upon as the active principle of yeast, gave equally good results, and would point to the action being due to the antiseptic properties of the yeast.

French Journals.

Treatment of Tinnitus.—After giving an anatomical description of the ear with illustration, and going over the various affections of the organ itself and of other organs capable of causing the symptom of buzzing, the various remedies employed are passed in review. Cimicifuga racemosa has been recommended by Robin and Mendel as a drug governing vascularity and a moderator of reflex irritation. It is used as a tincture (gtt. xv.–lx.), fluid extract (gtt. x.–xxx.), or cimicifugin (product of precipitation of the tincture by water (5–20 cgm.). These authors have found, with the exception of cases lasting over two years, that cimicifuga gives prompt and complete results.—*Bulletin Général de Thérapeutique, December 8, 1899.*

Autopsy of the Stomach.—Maurice Letulle, in a beautifully illustrated article, discusses examination of the stomach *in situ*, ablation, line of incision in opening, examination of the open stomach, cutting, coloring, preserving, etc.—*La Presse Médicale, December 13, 1899.*

Pertussis and Its Treatment.—E. Govin advocates aerotherapy, and his remarks upon local treatment can be summed up in the two words asepsis and antisepsis. —*Journal de Médecine, December 10, 1899.*

Anæsthesia by Nitrous Oxide and Oxygen.—R. Nogué presents a new inhalation apparatus which is illustrated by three drawings, and he cites instances in which it has been employed.—*La France Médicale, December 8, 1899.*

Expression and Digital Compression of the Prostate.—A. Guepin treats of massage in various forms as applied through the rectum.—*La Tribune Médicale, December 13, 1899.*

Localized Suppurations in Women After Delivery.—Grandmaison has recently studied three cases of localized suppuration after childbirth bacteriologically as well as clinically, and concludes that somatic causes have played the chief rôle. — *La Médecine Moderne, December 13, 1899.*

Il Policlinico, December 1, 1899.

Relative Toxicity of the Urine in Children and in Adults.—Ettore Santagelo states that in healthy adults the urotoxic coefficient, or the amount of urotoxins emitted during the twenty-four hours for each kilogram of body weight, is between 0.2 and 0.3. In healthy children the coefficient is between 0.3 and 0.4. The urine of children is less toxic than that of adults, but only absolutely so, for children in the twenty-four hours manufacture per kilogram of their body weight a larger amount of toxic principles than do adults in the same period of time and for the same weight. The physiological effects produced upon animals by the urine of healthy children are the same as those caused by the urine of adults. The toxicity of either adult or infantile urine is in inverse ratio to the total amount excreted in twenty-four hours, and in direct relation to the specific gravity, the depth of color, and the per cent. of urea of the urine. This points to the evident toxicity of urea. The toxicity of the urine in children suffering from ankylostomiasis differs but slightly from that of healthy children.

Polyclonia and Chorea.—Augusto Murri says that so far no essential distinctions have been established between polyclonia, tic, and chorea. This is probably due to the fact that these motor disorders all arise from one area in the brain. While many forms of choreic movements are now classified as symptoms merely, Sydenham's chorea must still be considered as a disease, because we do not as yet know with what morbid process it should be connected, but it is probable that it signifies some as yet unknown lesion in the "zone of Rolando."

La Riforma Medica, Dec. 4–7, 1899.

Experimental Researches upon the Action of Morphine on the Development and Course of Tuberculous Infection.—G. Tedeschi, desiring to ascertain the action of morphine in tuberculosis, inoculated a number of guinea-pigs with tuberculous sputum and then carefully noted the effect of certain given doses of morphine. The animals used are extremely resistant to morphine poisoning, but not immune. The lethal dose is about 0.06 to each 100 gm. of body weight, or 0.60 to each kilogram. The morphine was found to accelerate the disease instead of retarding it, but was less injurious in its effects the further advanced the disease. In practice, therefore, morphine should be resorted to in advanced tuberculosis only. Further studies upon this subject are desirable.

Toxic Psychoses due to Thyroidin.—Corrado Ferrarini reports the case of a young woman who developed symptoms of violent mental disturbance after the administration of thyroidin for the reduction of obesity.

Annals of Surgery, December, 1898.

Properitoneal and Interstitial Inguinal Herniæ.—Van Buren Knott has found only sixty-six cases of this nature on record. He relates a personal case occurring in a farmer aged sixty-four years in which operation was followed by an uneventful recovery. He was able to operate in five hours after the first symptom of obstruction had been experienced, but even here the vitality of the gut was so lowered by the extra pressure following its incomplete reduction, that the propriety of returning it into the abdomen was for some time in question. In all cases of inguinal hernia presenting an unusual location, or shape, of the sac, great care should be exercised that a reduction of a portion of the contents of the sac into another compartment of the same be not mistaken for a complete reduction into the abdomen. He believes that all cases of properitoneal or interstitial inguinal herniæ, whether strangulated or not, should be immediately subjected to an operation, as thereby the unusual dangers of this condition are minimized.

Operative Relief of Ectopia Vesicæ.—D. E. Mundell suggests the following method which he has successfully demonstrated on the lower animals: Transplant a portion of bladder wall of, say, a sheep to the lower lateral abdominal fascia of the patient. After a period of seven or eight days, the union of the two tissues is sufficiently strong to allow a plastic operation, whereby a skin flap with the bladder attached may be swung over upon the extruded bladder, and the edges of the attached piece of bladder sutured to the defective bladder. The skin flap will afford sufficient nourishment to the exsected bladder until union has occurred between the bladder edges, then the superimposed skin may be separated from the now perfect bladder. By employing a transplanted piece which has been removed from the lower portion of the bladder of the animal, the aggregation of the circular muscular fibres will approach very nearly to an ideal sphincter.

Nitrous Oxide and Ether by the Open Method.—A. H. Miller advocates the commencement of anæsthesia with nitrous oxide, and, as soon as anæsthesia is complete, the removal of the inhaler and the substitution of the ether cone. He has notes of one hundred and sixty cases in which no one has been conscious when the change was made or has experienced anything disagreeable from the anæsthetic. The average time required in his cases for anæsthesia has been 3.05 minutes.

Differentiation of the Urines.—F. Tilden Brown makes a plea for a more general employment of ureteral catheterization, claiming that it enables us to determine whether there is a urinary lesion present, and if so whether this lesion is in the superior urinary tract or the inferior. When a renal lesion exists we can determine which kidney is affected, what is the nature of the lesion, and what is the condition of the other kidney.

Persistent Thyro-Glossal Duct.—G. E. Armstrong has seen one instance of this in a boy aged six years. A small lump the size of a pea was situated in the median line of the front of the neck about three centimetres below the hyoid bone. It gradually became the size of a filbert, and the skin over it was red and inflamed. An incision discharged a colloidal material. The sac was scraped but refilled. Later the sac was again opened and the cyst wall and duct were dissected out. There was no recurrence.

Proper Wire for Introduction into an Aneurismal Sac.—J. C. Reeve, Jr., from experiments in passing wires of different kinds into a hardened bladder finds that a silver or gold wire, about .0085 inch in diameter, and of sufficient temper to retain its coil, would seem to be all that is required to fill, when carrying the positive galvanic current, an aneurism with clots, and is not so thin as to be in danger of breaking.

Mechanism of Fracture of the Neck of the Radius.—E. R. Corson has examined by the *x*-ray apparatus a case of this comparatively rare fracture. Its rarity is due to the fact that it enters only indirectly into the formation of the elbow joint. In the present case he was led to believe that the head was torn off from the neck, and he believes that this is the usual way in which the accident occurs.

Actinomycosis in Man with Special Reference to the Cases which have been Observed in America.—J. Ruhräh finishes in this article his elaborate study of this disease. There seem to be some sixty-five cases on record, all of which have been carefully analyzed. A voluminous bibliography is appended.

The Medical Examiner, December, 1899.

The Manner in which the Effect of Muscular Exercise upon the Heart and Blood-Vessels Alters the Expectancy of Life.—T. Sidney Short, after a brief description of the anatomy and physiology of the circulation and the effects of muscular exercise upon the human body, divides the takers of exercise into three classes: First, those whose muscles want exercise because they do not get enough. In these the heart muscle is not diseased but flabby, pale, and easily fatigued. Here exercise is a benefit and increases the insurance value of the risk. Too great exercise distends the heart because its walls have but little tone. Exercise must be moderate, frequently repeated, and regular. The second class consists of those who keep their muscles in good condition. Regular exercise is essential to keep them up to their normal state of health. The special danger to this class is a long continuation of slight over-degrees of strain. Long-continued stress of overwork of any kind gradually produces an effect which shortens their lives. The third class is made up of those who have some defect in the vessels. Exercise is not here to be wholly tabooed. Suitably arranged exercises can be taught one of this class until he has built up his heart to allow of his taking moderate exercise quite comfortably. When actual disease is present, exercise must be taken most cautiously, and all sudden strains absolutely forbidden.

A Study of the Head and Face of Interest to Medical Examiners.—William C. Krauss calls attention to the abnormalities of face, skull, eyes, and ears noted in a study of various types of degeneracy, and gives measurements of one illustrative case. The article is in essence a study of the practical application of the principles of modern anthropology to the work of the insurance examiner. Attention is called to the present incompleteness of the science, and the admission is made that no special type or types of cranial deformities or irregularities have as yet been found pathognomonic of any class or classes of degenerates.

Study of Four Hundred Cases of Tuberculosis.—The cases were all examined by C. A. McCollom for admission to one of the fraternal orders. He states that it takes five factors to make a "gilt-edge" risk: a full family age, clean family history, standard weight, clean personal record, and normal physiological condition. A minus combination of any three of these would constitute a questionable risk which might eventually develop tuberculosis.

The Use of Alcoholic Beverages as It Applies to Life Insurance.—P. J. Strathy makes three classes of drinkers—the tippler, the spree-devotee, and the man who is almost always temperate but has an occasional "festivity." If a man drinks frequently between meals, drinks early in the day (perhaps a cocktail before breakfast), he is not a fit subject for life insurance.

Ethics of Examining.—S. T. McDermith says that examiners should never compliment applicants upon their good physical condition, should never abuse the medical director at the home office if his recommendations are vetoed, and should give a full and free report of the pros and cons in a doubtful case.

Medicine, December, 1899.

Milk as a Carrier of Infection.—C. O. Probst describes the measures necessary for protection against milk infection. Since milk contains all the essential elements of food, its use is almost universal. It is an admirable vehicle for conveying to man many pathogenic micro-organisms. It may be contaminated by an infected atmosphere. Diphtheria, scarlatina, and typhoid fever are chiefly to be dreaded as agents of its infection after it has left the cow. Tuberculosis is perhaps a more important disease, and generally infects milk before it leaves the cow. There should be systematic, rigid inspection of the dairy itself, including the cows, their food and water supply, the stables, milk-house, and persons handling the milk. The permit system, depending on the results of inspection in each case, should be strictly enforced. There must be a revolution in the construction of cow stables. They must be light, clean, well ventilated, and spacious. Finally, the hearty co-operation of the dairymen is an important element of success in obtaining pure milk.

Malignant Tumors of the Eye.—William H. Wilder asserts that the malignant tumors affecting the conjunctiva are usually epithelial, although sarcoma sometimes appears at the sclero-corneal junction. Primary tumors of the cornea are extremely rare. New growths of the iris are not common. Of all tumors affecting the eyeball, those most to be dreaded occur in the choroid, ciliary body, and retina. There are four stages in the clinical history of these cases: (1) a period of early growth before there is any irritation; (2) a period of inflammation; (3) perforation of the eyeball and extension of the tumor outside the eye; (4) metastasis.

General Surgical Anæsthesia and Anæsthetics.—Ernest J. Mellish states that chloroform almost invariably kills by its effect primarily upon the circulatory system, and ether by its effect primarily upon the respiratory system. Anæsthetics act directly or indirectly upon all the tissues, interfering profoundly with metabolism. The anæsthetic should be selected according to the conditions present in the individual case. No person who has not a wholesome fear of anæsthetics can be trusted to administer them. The pupillary reflexes constitute the best guide in anæsthesia. Anæsthetic mixtures are generally less safe than the "straight goods."

The Treatment of Syphilitic Stenosis of the Larynx by Intubation.—Thomas C. Evans advocates intubation in syphilitic stenosis of the larynx for the relief of dyspnœa, adding that there is no shock nor hemorrhage nor danger of infection.

Dublin Journal of Medical Science, December, 1899.

Venereal Diseases and Their Therapeutics.—T. L. Swan says that the classification of venereal diseases into gonorrhœa, chancroid, and Hunterian chancre is unalterable, but that the three have nothing in common except locality. He describes the genesis and development of the soft sore, and notes the comparative absence at the present time of phagedæna. This he ascribes to the fact that as persons in civilized communities become immunized to a degree by a remote or recent inoculation by the microbes of the diseases of civilization, so persons showing no powers of resistance have either escaped the immunizing taint or it has become attenuated and lost. As to the treatment of syphilis he notes that the great difficulty is the length of time required to combat the periodic manifestations of the toxins. He prefers the intramuscular injections of the mercurial cream of Lambkin, the formula not being given. He adds a few words concerning two types of the disease occurring in individuals completely unprotected by influences which confer partial immunity, one malignant syphilis and the other syphilis tertiare precox. In the latter case, mercurials, iodides, etc., were without effect, but thyroid tablets given internally rapidly healed the rupial sores which covered the entire body.

Observations on the Treatment of the Third Stage of Labor, Especially as Regards the Delivery of the Placenta.—G. Cole-Baker has never seen in any text-book a description of what he regards as a perfectly satisfactory method of delivering the placenta and membranes. He applies a third ligature to the cord in addition to the conventional two, the third being two inches from the first and on its maternal side. The special points to which he calls attention are as follows: 1. The importance of the careful treatment of the third stage of labor, and unceasing control of the uterus during this stage; 2. The binder in many cases is superfluous; 3. The advantages of three ligatures on the umbilical cord; 4. Credé's method of expression relates only to the first step of the third stage; 5. Traction (vis a fronte) is equally good, if not preferable, treatment to "detrusion" in the second step of the third stage; 6. An ideal and perfectly satisfactory treatment for the third and last step of the third stage has yet to be described.

Innominate Aneurism.—J. Craig gives the notes of a case occurring in a man of sixty-five years. He was treated with morphine, saline laxatives, milk diet flavored with coffee, and a roast apple four times daily, and a daily dosage of gr. xv.-xxx. of sodium iodide in milk. All walking was strictly forbidden. At the end of eighteen months, except for a slight prominence and diminished resonance over the former site of the sac, all physical signs had disappeared and the patient was in excellent condition.

The Medical Chronicle, December, 1899.

The Dietetic Treatment of Disease.—J. Dreschfeld holds that in acute fevers it is well to give the patient an abundant amount of food, but not too much liquid food. In chronic, febrile diseases dietetic treatment is all-important, phthisical patients requiring thirty to thirty-five calories per kilo weight, so that quality should also be considered and much fat given. In gout, the nitrogenous diet is usually best suited to those cases in which the patient is stout, has dyspeptic symptoms, and passes urine not rich in urea. Some appear to do best on a vegetable diet. A diet rich in proteids and carbohydrates often gives rise to dyspeptic troubles. In diabetes the usual diet may often cause total disappearance of the urine, but fat and alcohol should be added to it. In chronic Bright's, the diet should contain a small quantity of proteids, and fat and carbohydrates give the necessary heat. In "dyspepsiæ" light and finely divided albuminous food is well borne by patients suffering from hyperacidity, and even when the hydrochloric acid is absent, if the motor power of the stomach is still intact. If not intact, small quantities of food in a concentrated form must be given. In order to obtain the proper nutritive value we should try to give fat in the various stomach affections. Butter, cream, and bacon are usually well digested, but cod-liver oil and pancreatic emulsion are sometimes better borne. Some functional derangements of the stomach are only types of neurasthenia and require forced feeding. These are cases in which there is pain after food, or persistent vomiting, with perhaps enteroptosis, displacement of the kidney, etc., and in which emaciatation takes place rapidly. Electrical treatment and massage are important aids, but often bodily rest, and the partaking of large quantities of milk, first alone and then in combination with carbohydrates and albuminous food, will obtain a cure.

Fractures of the Hyoid Bone and of the Laryngeal Cartilages.—J. E. Platt reports a case. The chief danger of such injuries, he says, lies in the interference with respiration, and resort to early trachelotomy would greatly diminish the mortality. If the fragments of a fractured hyoid bone be displaced inward, an attempt may be made to reduce them by a finger in the throat. The parts should be kept at rest, and, if the patient cannot swallow, nutrient enemata should be given. Accidents to the hyoid bone have originated in almos tall cases from some form of direct violence.

The Edinburgh Medical Journal, December, 1899.

Appendicitis.—Gilbert Barling reports one hundred and seventeen cases operated upon. In forty-two the operation was performed in a quiet interval, and only one death occurred. The remaining seventy-five cases he divides into four groups: 1. The "safe" abscess, with the pus so localized by adhesions that the surgeon opens into it without danger of infecting the general belly cavity. 2. "Non-adherent abscess" in which the pus is shut off from the general cavity, but the operator has to open the general cavity to seek it. 3. "Subacute," widespread suppurative peritonitis. 4. Acute fulminating peritonitis. Group 1 comprised nineteen cases with one death; group 2, twenty-one cases, no deaths; group 3, nine cases with three deaths; group 4, twenty-six cases with eleven deaths. The total mortality is twenty per cent., which the author considers to be in most instances the mortality of delay. The diagnosis of appendicitis being often difficult, the physician should see his patient at short intervals in the first three or four days of the attack. The great thing in recognizing a case suitable for operation is not to take any one point as essential to diagnosis, and to dwell not so much upon the absence of any one particular feature as upon the intensity of such symptoms as are present.

The Effect of Extreme Cold on Injury.—Henry A. Duffett reports two cases in which extreme cold had a beneficial effect on injuries by producing a form of dry gangrene. One was that of a sailor whose finger was injured by being caught in the cogs of a winch. It was wrapped in a not over-clean piece of lint, washed with ice-water. The cold was intense and the man was on deck constantly. A fortnight later, the author saw the patient, and found the joint black and shrivelled, insensitive and smelling foully. He amputated the finger; primary union occurred, and the man was at work in ten days.

Bacteriology of Typhus Fever.—Andrew Balfour believes that the diplococcus is derived from the blood, because it occurs so persistently in typhus and typhoid cases, and because of the post-mortem occurrence of an organism almost identical with that derived from the living blood.

Aconite Poisoning.—W. A. Potts reports the case of a man who swallowed half an ounce of liniment of aconite, and recovered under treatment with strychnine and whiskey.

Acromegaly.—G. A. Gibson reports a case which he describes at length. Treatment of this disease, he says, has been attempted in two directions—one the removal of the pituitary body, and the other the administration of extract of that body. Neither has given the slightest good result. The use of thyroid extract has frequently produced improvement, but, on the other hand, injurious results have been described. Remissions take place in most cases of acromegaly. The patient's strength must be supported, and any disturbing symptom treated. In Gibson's case the use of thyroid tabloids caused considerable improvement, accompanied by a steady loss of weight.

Atheroma of the Aorta.—John R. Ambler comments on the frequency of cases of this affection met with in post-mortem examinations. In one hundred patients in an asylum, the author found the condition in sixty-nine per cent. The average age of all cases in which atheroma was noted was: males 53.14 years; females 52.37 years. In general paralysis in which it was noted, the average age was: males 45.37 years; females 40.5 years. In phthisis pulmonalis, the average age was: males 41.18; females 36.46. Is this condition the result of impact of the blood, or of disease; and if so, what disease?

The Simulation of the Symptoms of Other Maladies by those of Chronic Renal Disease.—H. W. Syers thinks that unless the urine be systematically examined in all cases, renal disease may often be overlooked, as it simulates so many other affections. Its influence in the causation of cardiac lesions seems to be as important as that of acute rheumatism, and the effects even more disastrous. The arteries are also often affected, and inflammation of the pericardium may occur, although rarely. In middle-aged patients suffering from distention and pain after food, loss of appetite, and irregularity of bowels, it is never safe to omit an examination with cold nitric acid. Troublesome headache always calls for such an examination. Constipation alternating with diarrhœa is always suggestive of renal disease, as is uncontrollable or fecal vomiting. Tingling and numbness in one of the extremities with some headache and nausea may be the only early signs of cirrhotic kidneys, or there may be merely giddiness and swimming in the head. Various diseases of the chest may be simulated by kidney affections shown by modifications in the act of breathing. Anæmia is a well-recognized symptom of renal disease, and is sometimes practically the one feature in the case.—*Treatment, December 14, 1899.*

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 21, 1899.

William H. Thomson, M.D., President.

State Care of Consumptives.—On motion of Dr. C. E. Nammack, the following resolution, emanating from the Section on Medicine after its recent discussion of this topic, was adopted by the Academy:

"*Whereas*, The prevalence of pulmonary tuberculosis, especially among the poor, has been, and continues to be, the cause of more deaths among the citizens of this State than any other disease; and

"*Whereas*, The great value of treating this disease in special institutions, under proper conditions, has been demonstrated, both abroad and at home; and

"*Whereas*, The inadequacy of private endeavor, however well directed, in dealing with this enormous problem is admitted by all who have made a study of this question; therefore be it

"*Resolved*, That the New York Academy of Medicine recommends the establishment of State and municipal sanatoria for the treatment of pulmonary tuberculosis."

The Clinical Uses of the Sphygmograph.—Dr. R. Van Santvoord read a paper on this subject. He said that in the case of two vessels, one having twice the internal diameter of the other, it would take twice as much pressure over the latter to obliterate the pulsation in the vessel. One of the chief clinical uses of the sphygmograph was to enable one to detect high arterial tension in the early stage of its existence. Its presence was usually manifested by the flat top curve, and it was indicative of arterial sclerosis chiefly, although this was sometimes combined with contracted arterioles. A large number of sphygmograms were exhibited, and their meaning was interpreted. Several were pointed out in which the quality of the pulse, as determined by the finger on the radial artery, had been very far from the truth. They showed how very misleading the pulse might be, even to the touch of the experienced physician. His tracings also showed that excessively low tension might be of significance in chronic as well as in acute diseases. He had been puzzled repeatedly with complaints of faintness from patients shortly after taking a dose of nitroglycerin. This might be explained by an unusually rapid absorption of a dose which ordinarily caused no inconvenience. The chief objection made to the sphygmograph had been the different results obtained by different observers. It was true that the faulty application of the instrument would give unreliable results. The spring pressure must be carefully graduated, not only to the arterial tension, but to the calibre of the vessel. A series of tracings should be taken with a gradually increasing pressure on the spring and on the band holding the instrument against the wrist. For the latter purpose he had found it convenient to have a small tourniquet attached, one on either side of the instrument. It was well to remember that almost always when the first part of the curve was "nicked out" it indicated that the spring pressure was inappropriate. Failure to apply the middle of the pad directly over the artery sometimes resulted in giving a distortion to the tracing, resembling that given by too great tension of the spring. Occasionally arteries would be found which were too small to give a good tracing, and the same was true of cases in which the action of the ventricle was very weak. After an experience of fifteen years he had come to look upon the sphygmograph as very useful, and as presenting no more fallacies than other methods of investigation which no physician would think of discarding.

Dr. Louis Faugères Bishop said that the paper made it clear that the author had succeeded in obtaining more information from the sphygmograph than had many other physicians who used it, though perhaps less frequently. As the author had pointed out, one must be guided more by the shape of the tracing than by the actual amount of spring pressure in determining the arterial tension. He had personally always regarded as most nearly correct that tracing which gave the best picture. When there was a tracing without a dicrotic notch one could feel very sure that this defect was due to imperfect technique. Mention had not been made of the fact that the same tracings could be obtained by attaching a manometer to the cut vessel of an animal, an observation which was interesting as proving that the sphygmograph really did give a true picture.

Dr. S. J. Meltzer said that he had had some experience with the graphic method in connection with experimental research, although not so much with the sphygmograph. He would not trust himself to form any opinion from the form of a pulse tracing as to the character of the arterial tension. Statements had been lately made to the effect that the heart increased in size under exertion, and it would, therefore, be interesting to know whether, in the case in which the tracing had been taken from a person after exercise, an effort had been made to determine any coincident change in the size of the heart. No tracings had been exhibited in illustration of cardiac irregularity. For this kind of investigation the record should include a time-marking tracing.

Dr. H. W. Berg said that he had tried to make use of the sphygmograph, but had been unable to obtain tracings to which any diagnostic importance could be attached. The great difficulty seemed to be that in any given case tracings taken only a few minutes apart, with the same spring pressure, showed marked variations. Although twenty-six years had elapsed since Marey had first brought forward his instrument, and many competent observers had given their best energy and much time to the study of the sphygmograph, the instrument was still far from being practical and reliable. There was one exception to this statement, and that was the sphygmographic tracing of an irregular pulse, but even this did not add much to the value of the instrument in view of the ease with which such information could be secured from the finger on the radial pulse.

Significance of the Dicrotic Notch.—Dr. Andrew H. Smith said that he had used the sphygmograph a good deal some years ago, and had met with just the difficulties that had been emphasized by the last speaker. In some patients the artery was placed very deeply, and more or less overlaid by the tendons of the wrist, and, under these circumstances, it was very difficult so to adjust the instrument as to secure reliable sphygmograms. We had been taught to believe that the dicrotic notch was the result of a secondary wave taking place on the closure of the aortic valves, and yet sometimes a most marked dicrotic wave was obtained in cases of aortic regurgitation. It was not uncommon to be able to see, in the pulsation of the vessels of the neck, this dicrotic impulse, when the aortic valves were so much destroyed that one would not have supposed they could have produced such a result. He was inclined to think that, in some instances at least, the dicrotic notch was the result of a reflux of the blood in the opposite direction. If the conditions in the circulation beyond were altered, a change would result in the dicrotism, and in the general characters of the sphygmogram. For example, if the arm was ligated above the elbow, as for a venesection, the dicrotism would disappear, and all of the qualities of the high-tension pulse would be produced. In the same way, if the patient held his breath for some time, the tracing would show a very much smaller excursion. Again, it was not always easy to determine whether there was a sufficient degree of tension to give a slight excursion from tension, or whether this condition arose from the feebleness of the ventricular contraction.

Peculiar Tracings.—He recalled a case in which the sphygmogram had indicated forty beats to the minute, with fairly marked dicrotism and an enormous excursion. In this case, the rhythm had changed frequently, and, in the course of a single tracing, it had been possible to see distinctly where the dicrotic notch had increased in amplitude from one beat to another until it had finally equalled the amplitude of the regular stroke. The pulse had then changed from forty to eighty beats per minute, and it had been no longer possible to distinguish, either by the sphygmograph or by the finger, between the exaggerated dicrotism and the alternate beats.

Effect of Working in Compressed Air.—Some time ago he had employed the sphygmograph in observations on the men subjected to high air pressure while working in the caissons of the Brooklyn Bridge. This study had been exceedingly interesting, and had shown an increased amplitude, with more pronounced dicrotism and a greater frequency of the pulse. He failed to attach, however, much importance to the instrument, either as a means of securing a record or as an aid to diagnosis.

A Useful Instrument.—Dr. C. L. Dana said that he had succeeded in obtaining fairly uniform tracings and records with the sphygmograph which had been, at times, useful both for diagnosis and prognosis. He had confined his use of the sphygmograph almost entirely to persons who had reached the degenerative period of life, and in whom there were a certain steadiness and rigidity of the blood-vessels. Moreover, he had not been studying cardiac disease by this means, but rather the rigidity of the blood-vessels, the extent to which they were filled, and the strength with which the heart pumped the blood into them. Again and again he had found, in cases of apoplexy, a type of pulse giving an almost pathognomonic tracing. In these cases the vessels were dilated, but not well filled. These tracings seemed to him to show a need for strengthening the action of the heart, or at least for carefully watching the circulation. In certain classes of neuroses rather striking sphygmograms could be secured. Basedow's disease yielded a very characteristic tracing. The sphygmograph was also of some value in determining the quality of some of our drugs.

Application of the Instrument.—Personally, he never thought of keeping any record of spring pressure, nor did he strap the instrument on the wrist. The patient laid the hand on the table, and the examiner held the instrument on the wrist and endeavored to secure the best possible record. Three or four tracings should be taken under varying pressure. He was convinced that the instrument should be held by the physician, and not strapped to the patient.

Dr. Van Santvoord, in closing, said that, in some instances, the disappearance of the dicrotic notch was legitimate, and did not indicate faulty technique. He had not studied any of the tracings with reference to the effect on the rhythm of the heart of defects in the auricle or ventricle. In going over his records, in the preparation of this communication, he had been impressed with their very great uniformity under similar circumstances. Variations in the conditions would, of course, produce marked, but very readily interpreted, variations in the sphygmograms. He had not observed ordinarily marked variations in the tracings taken from the same patient under the same conditions at an interval of only a few minutes. He did not feel that he could take trustworthy sphygmograms without strapping the instrument to the patient's wrist.

Election of Officers.—The annual election resulted as follows: *Vice-President*, Dr. G. L. Peabody; *Trustee*, Dr. A. Jacobi; *Treasurer for the Trustees*, Dr. R. H. Sayre; *Treasurer*, Dr. H. L. Collyer; *Committee on Admissions*, Drs. C. E. Nammack and J. B. White; *Committee on Library*, Dr. Alfred Meyer.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, December 18, 1899.

Frederick Holme Wiggin, M.D., President.

Hysterectomy Without Preventive Hæmostasis.—Dr. A. Brothers presented a uterus containing a number of fibroids, in order to call attention to the method of hysterectomy without preventive hæmostasis—a method in vogue in Europe at the present time. This was the first case in which he had operated in this manner. The uterus had been seized per vaginam in the usual way, and the usual circular incision made, together with the upward dissection both anteriorly and posteriorly so as to open into the space in front as well as into Douglas' cul-de-sac. The uterus had then been seized higher and higher by traction forceps, and in that way the fundus was drawn down. Up to that time there had been no hæmostasis. In the present instance he had used clamps to the broad ligament, applied from above downward until three or four had been used on each side. In that case the indication had not been the presence of fibroids so much as the fact that the patient had been a sufferer from pelvic inflammation for thirty years. He had removed the uterus on one side completely and the uterine horn on the other side, leaving the diseased tube and ovary because of extensive and firm adhesions there.

Report of a Case of Alcoholic Cirrhosis of the Liver in a Baby.—Dr. R. Abrahams reported this case, that of a girl aged sixteen months, who up to the age of fourteen months had been in good health. Since that time there had been loss of appetite, increasing pallor of the face, constipation, and increase in the size of the abdomen. He had first seen the child on November 4th. The skin had then been dry and scaly, and the appetite capricious. There had been no hemorrhages from the stomach or bowel, and no jaundice. The abdominal distention had been extreme, the circumference at the umbilicus being twenty-six inches. Owing to the ascites the liver and spleen could not be defined. There was no effusion except that in the abdominal cavity. The diagnosis of cirrhosis of the liver had been made by exclusion. Syphilis had been excluded by careful inquiry and examination. An ascites from tuberculosis would develop more slowly than in this case. In the absence of œdema of the lower extremities and marked urinary signs and symptoms, interstitial nephritis had been excluded. It had been finally ascertained that since very early infancy the baby had been allowed to imbibe beer quite freely. For two weeks the child had been given two-grain doses of iodide of sodium, but without result. The ingestion of water had been restricted, the bowels kept relaxed, and the beer stopped. After a time paracentesis had been performed, and then it had been found that the liver was smooth and hard and extended down almost to the iliac spine. Since the tapping, early in November, there had been no return of the ascites. The liver had diminished slightly. The patient and photographs were exhibited.

Dr. H. Illoway said that numerous cases of alcoholic cirrhosis had been reported in children. Some physicians maintained that alcoholism was rarely a factor in the production of cirrhosis of the liver in children, yet personally he was firmly convinced that it was almost always the cause of this affection in young subjects. Dr. J. H. Musser, of Philadelphia had recently expressed the same opinion. Cirrhosis might develop almost any time after birth, but it was most common between the sixth and twelfth years. Mention was made by the speaker of a case of a child of two years, still at the breast, in which the mother had been accustomed to drink alcoholic liquors freely. Cirrhosis had also been ascribed to measles and scarlatina, yet in quite an extensive experience with these diseases he had never met with cirrhosis in children. It had seemed to him that beer had a more potent effect on the liver of young children than some of the stronger alcoholics.

Etiology, Diagnosis, and Treatment of Cystitis.—Dr. Ramon Guitéras read this paper. He said that cases of irritable bladder were often called cystitis, although really they were nothing more than the result of congestion of the neck of the bladder from a foreign body or from the irritating character of the urine. Acute cystitis was generally due to the extension of a gonorrhœa from the urethra during the third or fourth week, or to instrumentation in a case of posterior urethritis. Congestion or distention of the bladder wall, undue exercise, particularly bicycle or horseback riding, and exposure to wet and cold were important predisposing causes of cystitis. Frequent and painful urination, associated with the presence of pus or blood in the urine, were the chief symptoms of cystitis. Recto-abdominal palpation would reveal tenderness in the region of the trigone. Acute cystitis might be confounded with posterior urethritis, prostatitis, seminal vesiculitis, and vesical irritability. Posterior urethritis was usually an accompaniment of acute cystitis, and occurred before, and also after, the latter. In acute posterior urethritis the pus flowed back into the bladder, so that the urine would contain pus just as in a case of cystitis. When the urine was passed into three glasses, the last glass would be found to contain more pus than in a case of posterior urethritis. In a case of posterior urethritis the first glass would contain more pus than the other two, and would also show the presence of shreds. In cases of acute prostatitis there was pain in the rectum and on sitting, and rectal examination would reveal tenderness and enlargement of the prostate. In seminal vesiculitis rectal examination would show the vesicles to be enlarged and tender, and after the inflammation had subsided a quantity of detritus could be expressed into the bladder by massage. In chronic cystitis the patient would probably urinate ten or twelve times in the twenty-four hours, and the urine would be light in color and alkaline, and would contain some albumin or blood. When evacuated into three glasses the first and third would contain the most pus. In making the diagnosis of chronic cystitis, one must consider chronic posterior urethritis, chronic prostatitis, kidney lesions, and bladder irritability, as well as certain nervous affections. In cases of chronic posterior urethritis there were usually only shreds washed out, and these would be found chiefly in the first glass. In kidney lesions there was usually pain in the loin in addition to the physical signs of enlargement of the kidney. The pain of cystitis was more often referred to a point back of the pubes. In cystitis the pus was usually found associated with alkaline urine, while in pyelitis the urine was usually acid. In cystitis the pus was constant; in kidney disease it might be intermittent, and it was usually less abundant than in cystitis. Bladder irritability was distinguished from chronic cystitis by the absence of pus in the urine. Percussion and palpation would determine whether or not the bladder was enlarged, and palpation would reveal tenderness, enlargement, or the presence of calculi. The cystoscope would show a reddened and thickened appearance of the bladder in cases of ulceration. This instrument would also enable the operator to determine the presence or absence of calculi and tumors.

Treatment: In the treatment of acute cystitis, hot sitz-baths would be found of the greatest service. They should be given twice daily, as hot as can be conveniently borne. Hot rectal douches of saline solution were also beneficial. By the mouth the patient should be given alkaline diluents and antispasmodics. When the spasms and pain were severe suppositories of belladonna and morphine should be used. If the urethra was not too sensitive, bladder irrigations through the meatus were desirable. The best solution was the permanganate of potassium, beginning with the strength of 1 : 4,000 and gradually increasing until at the end of a week the maximum was reached—1 : 1,000. Subsequently nitrate of silver solution should be substituted, using at first 1 : 16,000 and slowly increasing it to 1 : 4,000. Sometimes it was better to make use of deep urethral instillations of five or ten minims of a solution of nitrate of silver, using a strength varying from one grain to the ounce to four grains to the ounce. Although in cases of acute cystitis it was not advisable to pass an instrument through the urethra into the bladder, such instrumentation was not usually contra-indicated in chronic cases. When the urine was ammoniacal nothing in the way of intestinal medication was equal to urotropin, given in doses of ʒ ss. three or four times a day. In cystitis due to stricture, it was well to dilate the stricture if possible, but if the stricture was very small and resistant it should be divided with a urethrotome, a Maissonneuve knife, or, if deeply situated, by external perineal section. When the prostate was very greatly enlarged enucleation should be done, but in the case of very moderate and hard hypertrophy of this gland he preferred the Bottini operation. Bottini's galvano-cautery knife not only reduced the size of the gland directly, but by destroying some of the blood-vessels diminished the blood supply, and so favored atrophy of the gland. When the cystitis was the result of tumor of the bladder, the tumor should be removed, if possible, by suprapubic cystotomy, cauterizing the base. In cases of malignant tumor of the bladder drainage would give relief.

Causes of Cystitis in Women.—Dr. Alexander J. C. Skene spoke of the etiology and treatment of cystitis in women. He said that the treatment did not differ from that of cystitis in the male, unless due to some other cause. What he would call the preventive treatment in women was by far the more important. The etiology was also quite distinct from that in the other sex. For anatomical and physiological reasons the bladder was far more exposed to injuries, and if he were to judge by his own experience he would say that the most frequent cause was trauma, either damage during parturition or surgical operations on the pelvic organs, or the use of instruments, such as the catheter. Cystitis in women was far more frequently caused by injury than by sepsis. The sepsis might be either from without or from within. Before the days of aseptic surgery the etiology of cystitis had been but vaguely known; subsequently it had been believed that cystitis was the result of the infection of the bladder by septic or specific germs, but this, he thought, was not the case. If this view was correct, then there should have been a disappearance of cystitis under aseptic precautions, but such had not occurred. Just as soon as it had dawned upon him that many cases of cystitis arose from the traumatism inflicted by the metallic catheter, he had substituted the rubber catheter. The result had been a very marked diminution in the number of cases of cystitis, although the same aseptic precautions had been taken in the use of both the metallic and the soft-rubber catheters. It was now very rare for him to see a case of cystitis after prolonged catheterization. He believed that cystitis could be produced by the decomposition of urine and the development of pathogenic germs, but this result was rare unless the mucous membrane had been injured by the catheter or by some surgical operation. Another class of cases coming under the same category were those in which the cystitis was the result of prolonged standing. This was far worse than long walking, because the latter stimulated the circulation, whereas prolonged standing gave rise to congestion and stagnation. These patients often complained of a feeling of weight and tenesmus, and were then seized with pain in the bladder and frequent urination. On examining the bladder in some of these cases he had found a small ecchymosis. With rest and simple treatment these patients would recover, but if they persisted in standing they would develop a well-marked cystitis. The most persistent and obstinate cases of cystitis that he had seen in women had resulted from a suprapubic cystotomy with the idea of draining the bladder. In many cases in which the vagina was rigid, drainage would be very imperfect, and unless the treatment was kept up the original inflammation would not be entirely cured. The patient being temporarily relieved by the drainage of the bladder, the fistula was usually closed, and then it would be found that the patient was worse than before. A piece of scar tissue in the bladder was almost sure, sooner or later, to break down and light up another attack of cystitis. Another cause of cystitis in women was physical exploration of the bladder, though done by the most scrupulously clean operators. He referred particularly to the dilatation of the urethra and catheterization of the ureters, and the use of the endoscope.

Methods of Diagnosis.—Very little damage to the mucous membrane would be sufficient to allow of the development of a cystitis. He contended that in nearly all cases a diagnosis could be made not only of cystitis but of the kind and degree of inflammation of the bladder, without making use of any of the instruments for internal exploration. For such information as he needed he relied upon a skilful analysis of the urine. It was very easy to exclude urethritis. The bladder having been allowed to become fairly well distended, the patient should pass a little urine to wash out the urethra, and then the urine should be collected and examined. If the bladder was washed out thoroughly, and then the next few drachms of urine secreted were found to contain the products of inflammation, it was almost positive evidence that the inflammation was in the ureters or kidneys.

Treatment.—For thoroughly cleansing the bladder he had found borax decidedly better than boric acid. It was important to remember that the fluid should be instilled—not injected—because the bladder should be allowed to fill very slowly. Care should also be taken not to allow the bladder to contract down upon the end of the catheter. The injection of an infusion of hydrastis, or of a very mild solution of nitrate of silver, was to be recommended in many instances. The stronger solutions of silver would certainly give temporary relief, but the ultimate result was not so good as when the solution was not stronger than one or two grains to the ounce. When a more decided effect was desired it could be more safely secured by the repeated injection of a mild solution. In addition to these measures he would make use of the constitutional treatment advised in the paper. However, when there were ulcerations such mild injections would not be sufficient. The ulcerated surface should be brought into view, and that particular area destroyed by a rather strong caustic application. Such an application to be effective must be circumscribed. In cases of cystitis caused by the presence of neoplasms in the bladder, he would recommend a method of treatment that had recently given him much satisfaction. This consisted in doing a suprapubic cystotomy, and then seizing the base of the growth, compressing it, and cutting it off with the cautery, or with the electro-hæmostatic forceps. This method, if properly carried out, was entirely bloodless, and left a most desirable stump, and one which healed in two or three weeks at the most.

Dr. Eugene Fuller said that all of Dr. Skene's cases of traumatism were examples of cystitis arising from infection. In the male much more difficulty was experienced in securing good drainage. Atony, traumatism, deficient drainage, calculi, and neoplasms might all act as causes to make the bladder receptive of germs. The most common mode of infection in the male was by an ascending infection from the urethra. In some severe cases of cystitis not only was the muscular coat involved, but the surrounding tissues were invaded. Here the bladder might become invested in dense adhesions and greatly reduced in size.

Washing the Bladder.—Dr. W. K. Otis emphasized the danger of mistaking disease of the kidney for disease of the bladder. Particularly in tuberculous disease the entire trouble might be located in the kidney, and yet the symptoms point directly to the bladder. In cases of chronic cystitis one must rely almost wholly on local treatment. In irrigating the bladder the effort should be made, not only to cleanse it thoroughly with an aseptic solution, but also to act directly upon the mucous membrane. When there was an associated posterior urethritis, the catheter should be introduced only just within the external sphincter. This would be known by the fact that on removing the syringe the fluid would not return out of the catheter, although fluid could be introduced into the bladder. Having moderately distended the bladder, the catheter should be removed, and the patient allowed to evacuate the fluid, thereby cleansing both urethra and bladder at the same time. When the disease was wholly within the bladder, a soft-rubber or a silk catheter should be employed. A total emptying of the bladder was secured by having the patient in the erect posture, and this should always be the position except when the person was too feeble. The double-current catheter was not to be recommended, as the fluid passed from one eye to the other without cleansing the bladder. Nor was it well to employ the irrigator. When the bladder was atonic, care should be taken not to distend the organ, and pressure should be made over the pubes so as to secure a thorough emptying of the viscus after the washing. Litholapaxy he considered the ideal operation in all cases of vesical calculus in which it was possible to introduce the necessary instruments. This operation was safer, and the convalescence was more rapid than after suprapubic cystotomy.

Dr. Guitéras closed the discussion. He said that trauma or anything else which caused congestion of the bladder should be looked upon as a predisposing cause of cystitis, the direct and active cause being infection. It was possible at the present time to sterilize even woven catheters by a short exposure to formaldehyde vapor.

Syphilis of the Nervous System, and the Use

and Abuse of Mercury and Iodine in Its Treatment.—Dr. William M. Leszynsky presented a paper with this title. He considered more particularly intracranial syphilis. Thorough treatment of syphilis in the early period after infection, he said, was generally considered to be the most effective way of preventing the disastrous phenomena of tertiary syphilis. One was forced to acknowledge, however, from clinical experience that even when such early and thorough treatment was carried out, the patient was not insured against the later manifestations, although usually when they did occur they were decidedly milder than in cases neglected in the early stages. All neurologists were familiar with the history of an initial lesion but an absence of recognized secondary manifestations. There was no known method by which the virus of syphilis could be eradicated so that the physician could assert positively that there would be no further manifestations. Recent exudative inflammations, gummatous growths, pachymeningitis, obliterative endarteritis, and periarteritis were the conditions which were most amenable to antisyphilitic treatment. In general, the results were observed within two or three weeks. The rapidity varied with the virulence of the disease, its duration, and the susceptibility of the patient to mercury and iodine. The preferable method of administering mercury was by daily inunction until the specific effect of the remedy was observed. Iodine, in the form of iodide of potassium, was given in saturated olution, beginning with ten minims three times daily, well diluted. Some patients could take readily as much as two or three drachms of the saturated solution three times a day. It had seemed to him that the action of iodide was more rapid than that of mercury, though he usually began with the mercurial inunctions. The use of the iodide should generally be continued until all active symptoms had subsided, though two or three months was about the average time. Much harm might be done to the general health by excessively prolonged and injudicious use of iodide and mercury. Thus, primary optic atrophy progresses more rapidly to complete blindness under such medication. Tonic measures of all kinds should be considered an essential part of the treatment. As a prophylactic measure small doses of the iodide should be administered for a short time about three or four times each year. When the diagnosis of syphilitic disease was doubtful too much dependence should not be placed upon the so-called therapeutic test. While it possessed at times a certain value, it was more often unreliable. It was well known that iodine promoted the absorption of non-syphilitic processes. It should also be remembered that syphilis could not be positively excluded, even when a case proved obstinate under antisyphilitic treatment. Patients with tabes who had never received antisyphilitic treatment since the onset of the tabetic symptoms should certainly receive a short course of such medication, but if this had already been done it was not only useless but positively harmful to repeat it. It was greatly to be deplored that many practitioners had accepted the opinion advocated so zealously by some, that without syphilis there would be no tabes. At the present time the prevention of syphilis was practically impossible.

Dr. Edward D. Fisher said that in all syphilitic disease of the nervous system the more acute the process the better was the response to antisyphilitic medication. For instance, in pseudo-general paresis under the use of one or two hundred grains of the iodide daily, in conjunction with mercurial inunctions, one frequently observed excellent results. Again, in all cases of ocular muscle paralysis coming on suddenly without any history of traumatism or rheumatism, it was fair to assume that the disorder was of syphilitic origin, and the treatment should be shaped accordingly. Tonics should always be administered in conjunction with antisyphilitic treatment. Spinal syphilis was frequently mistaken for tabes, the gummatous infiltration being in the same region, and giving rise to the same class of symptoms, except that tabes was never rapid in its course, whereas spinal syphilis frequently developed in the course of a very few weeks. In such a case he knew of no other treatment equal to the use of mercury and iodide. In cases of tabes exhibiting sudden exacerbations he would also make use of this treatment. Such symptoms were supposed to indicate the occurrence of a new gummatous infiltration.

Dr. Edward G. Janeway said that in suspected cases of cerebral syphilis the physician's first duty should be to try to determine the location and nature of the lesion. There might be, for example, a hyperostosis of the bones of the skull sufficient to give rise to marked symptoms. He recalled having seen an autopsy on a case in which a most distinguished neurologist had diagnosticated a tumor of the brain, and an unsuccessful attempt had been made to remove it by operation. No tumor had been found, but at the autopsy a syphilitic hyperostosis was found in the region in which it had been thought the new growth was situated. A gummous pachymeningitis was occasionally associated with hemorrhages, thus materially modifying the symptoms. Marked irritative phenomena might result from a very localized lesion on the surface of the brain, resulting in adhesion of the pia and dura. In two cases he had seen syphilitic hemiplegia from arterial obstruction at the end of five or six months; it was sometimes a precocious event. Sometimes very remarkable results were obtained from very moderate doses; in other cases, the mercurial and the iodide must be pushed vigorously. At times the iodide was not well borne by the mouth, and in such cases, or when the patient was in convulsions or was unconscious, the drug should be administered per rectum. When there was an individual intolerance to iodide of potassium, the iodide of sodium or the iodide of strontium should be tried, though he prefered the iodide of potassium whenever it could be taken.

Late Syphilitic Fever.—Incidentally the speaker mentioned the fact that there was sometimes a continued fever in tertiary syphilis, which was most apt to be mistaken for tuberculosis. In cases of this kind he had seen exceedingly good results from very moderate dosage; indeed, he had known such doses to succeed in some of the less urgent cases of cerebral syphilis.

Tabes and General Paresis.—He very firmly believed that the vast majority of the cases of tabes owed their origin to syphilis, and he held the same opinion regarding most cases of general paresis. In case of doubt he was in favor of giving the patient the benefit of the doubt by employing the therapeutic method of diagnosis.

Dr. Charles I. Proben said that it had been estimated that about two-thirds of all cases of syphilis failed to present tertiary manifestations. In cases of the degenerative type one could hardly expect to accomplish anything by antisyphilitic treatment. The latter acted on the granuloma tissue by producing fatty degeneration, and possibly also by acting on the germs in the blood. The lymphatic vessels were very early affected in syphilis, and in the clearing out of the lymphatics and of the blood-vessels, iodide was especially useful. When the patient was observed to be losing weight rapidly, the iodide should be reduced or withheld. This emaciation was most striking when iodide was given to a tuberculous individual.

Administration of Mercury.—Dr. Boleslaw La-

POWSKI said regarding the administration of mercury that in all severe forms of syphilis the quickest and safest method of giving the mercury was by inunction. Before beginning such a course of medication, the physician should first inquire whether the kidneys were able to eliminate the mercury. If these organs were found to be impaired, one must be very careful about administering mercury. Some cases of nervous syphilis did not improve until after prolonged treatment—perhaps not for three months. If there was reason to believe that scar tissue was present the specific medication should be persisted in for a long time, because it was well known that such tissue proved amenable to this remedy. His own opinion, based on a large experience, was that metallic mercury was the best form in which to administer this remedy, as it imposed less work on the system. The only exception he would make to this rule was when there was great urgency. In cases in which there was doubt, he would even be willing to make use of the rather dangerous intravenous injection of sublimate before saying to the patient that nothing further could be done.

DR. LESZYNSKY, in closing the discussion, took exception to the statement of Dr. Fisher, that iodide did no harm. It did harm in two ways, viz., (1) by interfering with general nutrition; (2) when given for a long time the patient became so accustomed to its use that, if urgent symptoms should develop the physician would be powerless to give relief. This was not theory, but fact. Cases of tabes with sudden accessions of symptoms were usually examples of pseudo-tabes. Most of the cases of cerebral syphilis in which he had used large doses of iodide of potassium had shown an increase in body weight. He had sometimes felt that he had hastened connective-tissue formation and destruction of nerve tissue by the administration of iodide. He had never made use of calomel injections, and would be loath to do so. Intravenous injection he did not think had been practised much on human beings; it was exceedingly dangerous.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, December 5, 1899.

FREDERICK PETERSON, M.D., PRESIDENT.

Multiple Sclerosis with Symptoms of Progressive Muscular Atrophy.—DR. GRAEME M. HAMMOND presented a case of multiple sclerosis occurring in the person of a man, thirty-eight years of age, exhibiting symptoms resembling those of progressive muscular atrophy. This combination, he said, was quite rare. The patient was a locomotive fireman by occupation, and had a good personal and family history. About one month after an attack of the grippe ten years ago his present trouble began. The first symptom had been a paralysis of the internal rectus of the left eye, and this had been followed by weakness of the left superior and the right internal rectus. At the present time, in addition to these symptoms, there was left hemianopsia. About one year ago there had been a sudden loss of smell on both sides. About six years ago he had begun to show symptoms of locomotor ataxia. The knee jerks were absent. Last January he had noticed weakness in the little and ring fingers of the right hand. This weakness had extended to the other fingers, and had been accompanied by atrophy. The atrophy was now well marked in both upper extremities, and fibrillar twitchings could be noticed in the affected muscles. These muscles responded slightly to the galvanic current, but not at all to the faradic. This history was very characteristic of multiple sclerosis. In 1897 a similar case had been reported in one of the German journals. In the case presented, true intention tremor and scanning speech were not present. It had occurred to him that the patient might be suffering from a progressive muscular atrophy engrafted upon a multiple sclerosis, but it was also possible that the sclerotic changes had taken place in an unusual position in the anterior horns. The optic nerves had remained normal.

DR. B. SACHS said that his impression was that the case might be almost anything else than multiple sclerosis. This diagnosis did not seem to him justified in the absence of nearly all of the cardinal symptoms. The case was certainly puzzling, but he was reminded of a case of tabes with progressive muscular atrophy, and he believed the president of this society had reported such a case some time ago.

DR. JOSEPH COLLINS said that he hesitated to make this diagnosis after a hasty and superficial examination; nevertheless he could not but feel that this was a case of locomotor ataxia plus progressive muscular atrophy. It was possible that it was an example of syringomyelia and tabes, for he had had such a case under observation for a long time.

DR. GEORGE W. JACOBY agreed with the last two speakers, for certainly, he said, the symptoms in the upper extremities and the optical symptoms resembled those of a nuclear affection, while the symptoms presented by the lower extremities were like those of tabes. It was, of course, rather presumptive to make a diagnosis after Dr. Hammond had studied the case so carefully.

DR. FREDERICK PETERSON thought this patient presented all the symptoms of locomotor ataxia. Atrophies of this kind were not very uncommon in locomotor ataxia. Several years ago he had exhibited to this society a case of typical locomotor ataxia with three symmetrical quadrants of vision lost, so that the person saw out of only one-quarter of each eye. He therefore looked upon the case as a locomotor ataxia presenting the unusual symptoms already cited.

DR. HAMMOND replied that at first he had also looked upon his case as one of locomotor ataxia with ocular symptoms, but on studying it more carefully he could not find the slightest indication of syphilitic infection, the man having indeed been singularly free from previous illness of any kind. He was temperate in his habits, was not neurotic, and presented an unusually good personal history. Again, his tabetic symptoms had not been at all prominent; the Romberg symptom was hardly noticeable, and there was none of the bladder or sexual symptoms of tabes. The fact that there had been lesions of the optic, the third, and the olfactory nerves, coming on respectively at intervals of several years, he looked upon as proof that this was a sclerosis affecting these different nerves. An affection of the posterior columns in disseminated sclerosis was not at all unique. The atrophy in the hands was, however, decidedly unique.

Intracranial Growth. — DR. PHILIP MEIROWITZ presented a man aged thirty-eight years, who had come to him on December 1, 1899, complaining of amblyopia of the left eye. He was entirely blind in the right eye from an injury inflicted with a piece of steel. The disturbance of vision had first appeared in the summer of 1898, and had reappeared four months ago. These "blind spells" had come on several times a day, and had lasted about eight minutes each time. They had continued altogether for about six weeks, and had been unaccompanied by pains. A tremor in the right upper extremity had also developed about the same time as the trouble with the eyes. Jerking of the right arm had been quite marked at night. Vertical headache had been present and quite troublesome some months ago, but it no longer occurred. About the middle of last July he had been seized with attacks of vomiting after taking food, and had improved under milk diet and the administration of iodide of potassium. About this time he had had a sudden loss of consciousness, and again two or three months ago. There was no distinct history of syphilis. Examination showed dilatation of the left pupil and good reaction to light, with absence of nystagmus. Tremor of the right arm was quite marked, and was aggravated by movement. His gait was good; the knee jerks were exaggerated; there was no ankle clonus. There were no sensory disturbances. Dr. Valk had examined the eyes with the ophthalmoscope, and had found a papillitis. There were no mental dulness and no impairment of the memory. The speaker expressed the opinion that there was an intracranial growth, and believed that its location in the cerebellum would account for most of the symptoms. He was inclined to believe that it was a syphiloma, because of the effect of treatment with the iodide, and the lack of definiteness regarding a possible syphilitic infection.

Dr. S. B. Onuf said that the patient had been under his care at the time that he had received the iodide. There had then been a staggering gait, a marked intention tremor, increased knee jerks, and ankle clonus on the right side. His eye showed marked choked disc and a number of retinal hemorrhages. He had at first hesitated between a diagnosis of tumor and multiple sclerosis. Dr. Coffin had expressed the opinion that the shape of the hemorrhages—small and wedge-shaped—pointed rather toward syphilis. The man had then been put upon rapidly increasing doses of the iodide, and had improved promptly. The dilatation of the pupil and the intention tremor were notably controlled by this treatment. He did not doubt that the trouble was syphilitic, but could not accept the theory that all of the symptoms could be explained by one syphiloma.

Dr. Meirowitz replied that Dr. Francis Valk, in his recent ophthalmoscopic examination, had found the retina entirely normal. The absence of disturbance of speech and of nystagmus, and the presence of papillitis, seemed to him sufficient to exclude multiple sclerosis. It was, of course, quite possible that there were a number of lesions, but when the symptoms could be explained by one lesion, this course seemed the more rational.

Two Cases of Tumor Compressing the Cauda Equina; Removal; Recovery.—Dr. B. Sachs reported these cases (see page 7).

Dr. Joseph Collins said that the cases presented should be a cause for much congratulation of the reader of the paper, as well as of the surgeon who operated. The history of the first case seemed to him to have pointed unequivocally to the presence and location of a intraspinal tumor, and he was glad that Dr. Sachs had had the courage to urge operation. He was reminded of a case seen by him in which he had endeavored to have a glioma operated upon, but the surgeons had arrived too late to be of assistance. He felt sure that the mortality in these cases was not so great that neurologists should not be on the alert to diagnose them and urge operative intervention.

Dr. Peterson added his congratulations to those of the last speaker. It seemed to him that tumors in this particular locality were more difficult of diagnosis than in other portions of the cord. One important feature of the paper was the aid that the sensitive area or the deformity had given in establishing the diagnosis.

Dr. Sachs, in closing, emphasized the point that even if the sensory changes were very slight, they should be reckoned with in making the diagnosis. This had been well exemplified in the first case. Another point insisted upon was, that he had managed by pressure upon a definite point to elicit the same pain as that of which the patient had complained. This had been extremely well marked in the first case.

Dysphrenia.—Dr. William Hirsch read a paper with this title. He said that the term "dysphrenia" had been applied to the secondary or sympathetic psychoses in contradistinction to the idiopathic or mental diseases, such as mania and melancholia. The secondary psychoses which were produced by bodily diseases were not characterized by the same uniformity of symptoms that marked the idiopathic variety. In the secondary psychoses there were frequent remissions with perfect lucidity during the course of the disease. Outbreaks of violence might be quickly followed by stupor. The speaker said that a further characteristic which he would call attention to was the occurrence of somatic symptoms, as loss of pupillary or patellar reflexes, rise of temperature, irregularity of the heart action, and certain vasomotor phenomena, such as œdema. In the secondary psychoses, the interstitial tissues, and particularly the blood-vessels, were the ones first and mainly affected. This was in accordance with the accepted pathology of the systemic spinal diseases. The changes in the interstitial tissues were produced by the diseases starting outside of the brain, such as the acute febrile diseases. There were a few cases in which, purely from the mental symptoms, one was justified in making a diagnosis of dysphrenia, even though ignorant of the exact nature of the underlying bodily disease. A case of this kind was then reported by Dr. Hirsch. The patient was a young and neurotic girl, seen by him first on September 5, 1896. She had then presented the condition of hallucinatory confusion. After an interval of quiet, on February 17, 1897, she became violent, and developed hallucinations of hearing and sight. At this time the temperature was normal. After about ten days she became stupid; her pupils were contracted, and the pulse was 60. After about one week, automatic movements of the hands and head appeared. On March 14th menstruation came on, and she quickly became normal, and remained well for ten days. In April, 1897, she was given thyroid extract, and quickly recovered. She remained well for nearly two years. On February 2, 1899, she unexpectedly developed the same violent symptoms as before. She showed some transitory improvement again under the administration of thyroid extract, but soon passed into a condition of dementia. After about three months she became quieter; the pupils and patellar reflexes returned; the temperature became normal, and her breasts, which had been much enlarged, returned to their natural size. Since that time her mental state had been good. The clinical features of this case evidently did not correspond to any primary psychosis. A loss of reflexes was generally considered as indicative of permanent change, but it was not impossible that this symptom might exist in functional disturbance. In the case just reported he believed that the menstrual disturbances were not the cause, but a symptom of the disease, as in the fourth, or worst, attack menstruation had had little or no effect on the mental state. The speaker suggested that the term "originary dysphrenia" should be applied to those cases which, in their clinical aspects, resembled those known to be produced by toxic or infectious agents, but in which no cause for such infection could be found.

Dr. Brown said that he had been deeply interested in the paper, and had seen a number of somewhat similar cases presenting apparently a physical basis for the mental disorder. In some cases of even very severe mental disease the mental symptoms would clear up during the later stages, for example, of a tuberculosis.

Dr. Mary Putnam-Jacobi asked Dr. Hirsch if he looked upon general paresis as a secondary psychosis, and also in what way the case of dysphrenia reported by him differed from recurrent attacks of hysterical insanity; also how far the failure to distinguish personality was really a mental symptom and how much the result of personal caprice.

DR. B. SACHS said that probably all present had seen cases similar to the one described. He had himself had under observation a number of women between the ages of fifteen and twenty years who had passed through very remarkable periodical mental changes. He had been much impressed with the suddenness with which these changes had occurred. All of these patients had been members of strongly neuropathic families. They had passed quickly from a condition of mania to one of depression. A patient now under his care had regularly had periods of six months or more in which she had been in a condition of maniacal excitement, and had then very suddenly passed into a condition apparently normal, but really only a stepping-stone to a period of excitement. It was questionable, in his mind, whether the class of cases spoken of in the paper represented a distinct entity in mental diseases. Such marked physical changes as had been described in the paper had not come under his observation.

DR. PETERSON expressed his belief that dysphrenia would be a convenient term for those cases which it would be difficult to describe under other names. The trouble was that these terms in psychopathy were usually founded upon clinical symptoms, with but little reference to the pathology, so that after a time the word came almost to include all insanity. Last summer, at Heidelberg, he had found about four varieties of insanity recognized, viz., paresis, senile dementia, katatonia, and dementia precox. About fifty per cent. of the cases in Germany at the present time were called katatonia, and the remainder were included under the term dementia precox.

DR. HIRSCH closed the discussion. He said that it was certainly remarkable how many insane patients would pass through a disease like typhoid fever without developing any mental symptoms—indeed, the patient whose history had been given had just passed through a typhoid fever in this way. He, too, recognized the great evil that had resulted from introducing names into psychiatry; but dysphrenia was not a new name, and certainly was useful in connection with a case like the one reported, which could not be well placed in any other classification. Dr. Sachs had referred particularly to circular insanity—to cases essentially chronic in their nature—but he had been discussing cases that were really acute. The mental disease consisted of a series of psychopathic conditions. The diagnosis of dysphrenia could be made only from a detailed history and long study. By a primary psychosis he meant a mental disease originating in the parenchyma of the organ; by a secondary psychosis one originating in the interstitial tissue; hence general paresis would be a secondary psychosis.

Blindness in Finland.—The different degrees to which blindness prevails among various populations is always a matter worthy of study. J. Widmark has investigated the subject as regards Denmark, Sweden, Norway, and Finland (*Nordiskt Medicinskt Arkiv*, August; *New York Journal*, October 25th). He finds that for every ten thousand inhabitants there are 5.3 blind persons in Denmark, 8.3 in Sweden, 12.8 in Norway, and 15.5 in Finland. The preponderance in Finland, which is not observed among children under ten years of age, is attributed to the great prevalence of trachoma. Curiously enough the "endemic" affects only the natives.—*Sanitarian.*

OUR LONDON LETTER.

(From our Special Correspondent.)

THE WAR—THE TWO ADJOURNED DEBATES: TUBERCULOSIS AND TABES—GUY'S HOSPITAL GROUNDS—THE LATE DRS. STARK, HAMILTON, HICKS, AND PRENDERGAST.

LONDON, December 15, 1899.

THE war is absorbing all our conversation. Even when we meet to discuss medical and other peace topics, as soon as the debate is over groups are asking one another their views of the latest telegrams. It seems therefore an unfortunate time for the two set discussions of our two leading societies to have extended over three evenings each. Still this wealth of material must be utilized, and news from the war has not at this date reached, nor can it for some time reach, a point when its surgery can be fitly considered.

To our debates, then. That on tuberculosis was concluded on Tuesday, having been resumed by Dr. Sidney Martin, who said that although tuberculosis was so prevalent mankind must be considered immune, as healing was common. In the lungs reinfection from without was frequent. The primary attack might be recovered from. In an interval of a few months to many years a second attack, varying in seat, would occur; so again a third attack. Of course either might be fatal. The result would be determined by the extent of the damage and the virulence of the infection. Such points were important in discussing treatment; so too was that of secondary infections, as streptococcus, in regard to which hygienic surroundings and pure air were the best preventives. Drugs could not be discarded. Antiseptics by mouth or subcutaneously were futile. To increase the patient's resistance was the chief aim. Open air did this; so did rest during febrile states, and judicious, not over-feeding. Destruction of sputum and boiling of milk prevented re-infection.

Dr. J. E. Pollock remarked on the decline of consumption in this country, and said open air was no new treatment. He had recommended it in a paper in 1865. Fresh air was best in the open if the temperature suited the patient and sunshine was to be had. Sanatoria were good for the poor, but had disadvantages for those who could afford more care and comforts or change of climate.

Dr. Drewitt insisted on the difference between fresh air and draught. Ventilation should have more attention. Diet was not sufficiently considered. Carnivorous birds were not so liable to tubercle as the seed-eaters—a fact to consider. Scotch-oatmeal feeders, he said, were scourged by tuberculosis.

Dr. Washbourn said at first phthisis was a purely tuberculous process when the natural defences could limit it. Impure air brought secondary invasions—the great risk, *e.g.*, pneumococcus and streptococcus.

Dr. Walters said catarrhal patients needed a higher temperature than others and were more affected by draughts.

Dr. P. Weber dwelt on the importance of a flesh diet, Dr. S. Watson on climatic influences, and Mr. P. Gould on surgical tuberculosis, in which, he said, the social position of the patient was most important in prognosis.

The president (Mr. Bryant) added his conviction of the extreme importance of fresh pure air in operative cases and no doubt in others also.

Dr. Fowler replied at length, maintaining his views and expressing himself most hopefully if only the treatment was carried out for the benefit of the patients and not exploited commercially. He held that there was no pathological basis for the belief in the importance of septic organisms. Their action would produce septicæmia, and in the vast majority of cases there was no evidence of this. The rectal temperature he had known to explain non-progress and so be a guide to a puzzling case. The open air produced a veritable air-hunger, and so rendered patients apt to neglect the direction to avoid draughts. He preferred carbohydrate and fatty food to nitrogenous. The treatment should be continuous night and day and extend over long periods. The difficulty usually was to get doctors and patients to realize how long it must be.

The Pathological Society's debate on the relation of tabes to general paralysis of the insane was resumed by Sir William Gowers, who found little to criticise in Dr. Mott's paper. The preponderant relation of tabes to syphilis he considered was now admitted as fact. In his last one hundred private cases syphilis was unquestionable in sixty-eight and probable in twelve. In the remaining twenty cases it was possible, as there had been exposure to the ordinary risk and in some cases gonorrhœa had been taken. In six cases of juvenile tabes he had met with, the evidence of inherited syphilis was clear. His experience confirmed Dr. Buzzard's, that when the two diseases were associated tabes preceded paralysis. The theory that the changes in the posterior columns depend on the meningitis was strenuously advocated twenty-five years ago, though perhaps not precisely in the form suggested by Dr. Bruce, but it had been abandoned for good reasons, *e.g.*, the inconstancy of the extra-neural changes or the failure to account for some of the most remarkable facts of tabes. The question of the identity of tabes and paralysis he regarded as very much one of words, but he asked whether common causation could create identity in diseases differing widely in symptoms? Does not the common use of the word disease refer to a definite aggregation of symptoms rather than to causation? As to the question asked by Dr. Mott, whether the toxic agent lowers the durability of the nerve elements so that some other factors induce a premature decay, Sir William Gowers had long taught that that is the secret of the incidence of degenerative diseases. An average normal man he thought inherited equal vitality in all his structures, and went to pieces at last like the "one-hoss shay" in mature, equable, and senile decay. At the other extreme were patients whose structural elements were deficient in some part of the muscular or nervous system, so deficient in some cases that they decayed as soon as they were completely developed.

Dr. Savage admitted that in both general paralysis and tabes the evidences of destructive changes were similar, but thought that it did not prove that exactly the same causes had been at work. The débris in a wrecked house was the same, however the fire originated. On the clinical side the toxic element affected the least stable and most developed tissues. All the symptoms of general paralysis might be seen in the various stages of alcoholic intoxication, and similar symptoms occurred in plumbism and in influenza. The same parts were affected by the poison. Only in the more stable poisons or in those which had a specially pernicious effect on the tissues did decay ensue. He was convinced that syphilis played a most important part in both diseases. He observed that tabetic symptoms often preceded general paralysis by years, but he had also seen many patients who had had tabes and insanity for many years without becoming general paralytics. Many tabetics improved in their ataxy with the development of mental symptoms. In an asylum patients are met with suffering from general paralysis, having every degree of ataxy. The ataxic symptoms were very rare in females. Though not quite convinced that the two diseases were one, he admitted they had similar causes and left similar pathological débris. He thought a toxic cause was the chief one and syphilis the most common toxin. In some cases he believed there might be an autotoxin from rapid brain changes as in acute delirious mania.

Dr. Ferrier favored the view that the two diseases were the same, probably due to the same cause—syphilis either hereditary or acquired. All other assumed causes had been found wanting. The pathological process was sclerosis, whether inflammatory or not, and the question remained why in one case the cortex was affected and in another the posterior columns.

Dr. Payne said that the specimens now shown by Drs. Mott and Batten supplied the anatomical proof of Fournier's clinical conclusion, that the two diseases were closely related and probably identical. A common syphilitic origin went far to prove identity. Once diffuse cirrhosis of the liver due to syphilis was not admitted; other instances of diffuse inflammation produced by syphilis had been admitted in recent years only. He had seen primary lateral sclerosis improve under antisyphilitic treatment.

Dr. Hale White said that while there were two groups in which syphilis affected the cortex and the cord, so there were cases in which the first effect was seen in the peripheral nerves. That the same cause might damage sometimes one part, sometimes another, was seen in lead poisoning.

Dr. Batten gave an account of his investigations, illustrating it with specimens and lantern slides, and promised to bring before the society some further researches on the subject. He dealt on this occasion with the condition of the peripheral nerves and the origin of the degeneration of the posterior columns. As to the latter he held there was considerable evidence in favor of Dr. Bruce's suggestion. He said degeneration of the posterior columns occurred in cases of cerebral tumor, and in some cases was limited to those columns, the roots being unchanged.

The debate was at this point again adjourned.

While excavating in the grounds of Guy's Hospital lately the workmen came on an accumulation of human bones and a number of tobacco pipes. Some years ago a large number of skeletons were removed from the grounds when digging the foundations for additional buildings. It is conjectured that the hospital was built on the site of a burial ground for victims of the great plague.

Dr. Stark, who was killed by a shell at Ladysmith, was a well-known naturalist who was engaged in classifying the plants and fauna of South Africa, and on the outbreak of war offered his services to the army. Probably you have read that the only words he spoke after being hit by the shell were, "Take care of my cat." It has been conjectured that the last word was not completed, and should be catalogue.

Mr. Edward Hamilton, of Dublin, died on the 7th instant, aged seventy-five years. He had been three times president of the College of Surgeons there, viz., in 1875, 1892, and 1893. As a teacher and a surgeon he long held a most important position, and all through his career received the respect of all who knew him. Few men could be more esteemed by his brethren and by his fellow-citizens.

Dr. Henry Hicks, F.R.S., whose death occurred on the 18th ult., was well known as a geologist. He was president of the Geological Society, 1896-98, and received the diamond jubilee medal in 1897.

The death is also announced of Inspector-General Prendergast, in his ninetieth year. He had a distinguished career, and was present at the chief battles in the Crimea.

It is one thing to write and another thing to have readers. The test of what a man can do is the number he can interest in his work.

THE PATHOGENESIS OF GENERAL HÆMACHROMATOSIS (DIABÈTE BRONZÉ).

To the Editor of the Medical Record.

Sir: Apropos of the article of Dr. H. W. Berg, in a recent issue of the Medical Record, permit me to make a few remarks regarding the pathogenesis of diabète bronzé, or, as it is now properly termed, general hæmachromatosis. The characteristic features of this disease consist: (1) in the deposition of an enormous amount of an iron-containing pigment in the liver, pancreas, gastro-intestinal canal, skin, lymphatic glands, etc.; (2) in hypertrophic cirrhosis of the liver and the pancreas; and (3) in the onset of diabetes mellitus, which appears either periodically or only as a terminal event. Regarding the source of the iron-bearing pigment, all writers seem to agree at present that it is derived from the hæmoglobin which was separated within the blood-vessels from the red corpuscles by some pathological process. As to the nature of this factor the diverging opinions can be classified under two heads. Some, perhaps the majority, of the older writers consider the diabetes as the primary cause of the group of symptoms, and assume that the excess of sugar in the blood is, in some way or another, responsible for the destruction of the red cells. Another group of authors, consisting mostly of recent writers on the subject, believe that the destruction of the red blood corpuscles is caused by some unknown agent, and that the degenerated hæmoglobin is deposited in the cells of the liver, pancreas, etc., causing an interstitial inflammation of these organs, which subsequently leads to a "pancreatic diabetes."

The purpose of these lines is to put forward a new suggestion; but, before doing so, I wish also to offer some discussion of the hypothesis set forth by Dr. Berg in his interesting paper on diabète bronzé. The hypothesis belongs to the first category; it simply assumes that the excess of sugar in the blood causes the separation of hæmoglobin from the stromata of the red cells within the circulation. It seems to me, in the first place, that this hypothesis does not fit Dr. Berg's own case, inasmuch as pigmentation of the skin of his patient appeared eighteen months before the diabetes set in. Then if it be true that the excess of sugar in the blood always causes a solution of the red cells, why should there be among the great number of cases of diabetes only so very few—twenty-four—cases of the bronzed type? Again, of the great number of investigators on the character of the blood in diabetes, nobody has ever observed the presence of any unusual number of "shadows," red cells without hæmoglobin. The weakest point, however, of this assumption I believe is its reasons. I shall discuss only one point. Because Brasol has shown that when sugar is injected into the circulation it causes a passage of fluids from the tissues into the blood-vessels, and because the addition of water to blood dissolves out the hæmoglobin from the red-blood globules, Dr. Berg comes to the conclusion that red cells must become dissolved in diabetic blood. Was the dilution of the blood in Brasol's experiments caused by the entrance of water into the blood-vessels? Dr. Berg himself uses the expression "fluids from the tissue," which is an isotonic fluid, and does not dissolve red cells. The physiological process in the experiments of Brasol is simply as follows: The introduction of a very concentrated solution of sugar, forty to fifty per cent., into the circulation increases considerably the osmotic pressure within the blood, and causes a stream of the tissue-lymph into the blood-vessels till the hypertonic blood serum becomes isotonic. At no time during this process are the blood cells bathed by hypotonic fluid, and it is a hypotonic fluid alone which can separate the hæmoglobin from the stromata of the red cells.

The suggestion which I wish to offer is as follows: In general hæmachromatosis there is an enormous amount of iron-bearing pigment deposited in nearly all the organs of the body. This iron comes from the red cells. But examination of the blood has not revealed any noteworthy diminution in the number of the red cells nor a reduction of hæmoglobin. Nor is the presence of hæmoglobinuria noted in any of the described cases. In short, there is no indication of a pathological condition of the blood. On the other hand, blood diseases, even pernicious anæmia, do not produce hæmachromatosis. Neither did the experiments with the blood destroying poisons lead to real hæmachromatosis. All this seems to speak against the assumption that a pathological condition of the red cells is at the bottom of this disease. From where, then, is the enormous storing up of iron in the organs of the body coming? I answer, that the seat of the trouble is perhaps located in that part of the mechanism of the iron metabolism which is entrusted with the removal of the iron from the body. Only very small amounts of iron are absorbed, and about the same quantity is excreted again, mostly by the mucous membranes of the intestines. Perhaps, then, by some fault in this mechanism the organs and cells of the body retain all or most of the iron which reaches them on its normal round through the body. This hypothesis has the merit that it is accessible to an experimental test. If the assumption is correct, an analysis of the fæces would reveal any deviation from the normal. S. J. Meltzer, M.D.

"IS STATIC ELECTRIFICATION A SPECIFIC FOR ORGANIC AND STRUCTURAL NERVOUS DISORDERS?"

To the Editor of the Medical Record.

Sir: Dr. Rockwell asks this question in your last issue, after reading my article in your issue of December 9th.

The question, as put, utterly misrepresents the spirit, meaning, intent, and facts of my article. Electrification is the production of an electric charge; electrization is to subject the human body to the action of electric currents. The former would not disturb a timid child; the latter may force a giant into fixed contortions or kill him. My entire article, as its title states, was devoted to the use of currents (and incidentally sparks) and therefore to electrization. Will any one deny that electrization will affect organic and structural diseases? The "specific" and "panacea" ideas we leave to our critic.

However, as to one point, Dr. Rockwell may be taken seriously. He denies my originality as to the static induced current. He has in his possession "an old, old book by one named Mauduyt," etc., which gives "in descriptive and illustrative detail what is now called the static induced current."

I have also in my possession a dozen or more "old, old books," among them this same author, Mauduyt, and plenty of new ones, all of which give exactly what Dr. Rockwell refers to as given in his Mauduyt. I have searched these books long and carefully to find any allusion to the form of current which I named the static induced current. So have many others. Nowhere is there any reference to a current which will produce a continuous muscular contraction, namely, physiological tetanus, similar to that produced by the faradic current. These authorities deal with the spray, sparks, and mainly with shocks from Leyden jars. To graduate the length of the spark from a Leyden jar and thus to define the limit of the shock, the Lane electrometer, which is simply a Leyden jar with modified metallic connections and other contrivances, were used. The result was a single spark from the jar and a single muscular contraction. It is to this Lane electrometer form of Leyden jar that my critic undoubtedly refers. Let us see what Mauduyt, his own authority, actually says of it. I translate: "Its advantages are (1) to furnish a sure and fixed measure of the force of the shocks; (2) to give them at a strength which is agreeable; (3) to preserve this strength as long as is thought suitable, and to be able to augment or diminish it at will; (4) to determine and regulate their course." Not a word is said of a tetanizing or, so to speak, faradic current, such as the static induced current is, in these conclusions from Mauduyt (nor elsewhere in his writings).

If Dr. Rockwell will produce any record or instance, prior to my publication in 1881, of a current derived from electrostatic apparatus, which has in any one's experience produced physiological tetanus, namely, continuous muscular contractions, as does a faradic current, then I will withdraw any claim to originality for the discovery of the static induced current I have ever made. If, on the other hand, he cannot sustain his statement, let him frankly say so.

William J. Morton, M.D.

December 27, 1899

A REVIEW OF THE HISTORY AND LITERATURE OF APPENDICITIS.

To the Editor of the Medical Record

Sir: In a review of the "History and Literature of Appendicitis," by Dr. George M. Edebohls, in your issue of November 25, 1899, referring to the various operative measures he says: "The expedient adopted by Wyeth of operating at two sittings represents an unnecessary compromise." This "compromise" is in my opinion so essential to the safety of the patient in a large proportion of certain forms of appendicitis that I desire to state my position clearly, and with emphasis. I hold that in many instances unnecessary dangers are incurred by the boldness of certain operators in the efforts to remove septic accumulations from the peritoneal cavity. To advise in all cases a free dissection for the removal of the remains of a diseased appendix and the plastic exudate, which with the mesentery and contiguous intestinal loops form the wall of an abscess resulting from infectious appendicitis, is to encourage a dangerous practice.

In the earlier hours of infection, when the amount of septic matter is small, and the adhesions and area of infection are limited, a complete operation which will require no more than the "gridiron" incision of McBurney can often be done with perfect propriety and with safety by a skilful operator. In my experience, these cases are, however, very rare. When there has been a considerable exudate measuring with the agglutinated mass three or four inches in the various diameters, these complete operations cannot without grave risk be safely accomplished unless the incision through the abdominal wall is enlarged in order to give the surgeon complete control of the septic area, and thus prevent spreading the infection to uninvaded portions of the peritoneal cavity. Enlarging the incision by division of the muscular fibres is very objectionable, for the reason that it weakens the abdominal wall, and not infrequently results in ventral hernia. When an abscess has formed, and this abscess can be opened directly through any part of the abdominal wall in which adhesions exist which enable the operator to drain the septic contents off without entering the general peritoneal cavity, I hold it is better practice to do this than to attempt removal of the infectious mass. The vast majority of these patients recover, and only a very small proportion of them have a second attack. Should a second attack occur I should carry out the same line of practice, and insist upon a removal of the diseased appendix after the acute infection had passed, and in what we call the quiescent period.

In the larger abscesses, in which no adhesions have occurred between the mass and any part of the abdominal wall, I make it a rule, after making the gridiron incision and discovering this condition, to insert gauze in such a way as to keep the wound open, and to secure adhesions between the mass and the peritoneum at the margins of the incision, waiting twenty-four to forty-eight hours to institute drainage For this second operation cocaine anæsthesia is sufficient.

One other point I would like to bring up. Dr. Edebohls says: "Ligation of the stump, though still very generally practised, cannot be considered a perfectly safe procedure." There does not seem to me to be much force in this criticism. It may be asked if any method of closing the opening in the appendix or cæcum can be considered a perfectly safe procedure. With one or two exceptions I have practised simple ligation of the stump with a silk thread in all of my cases. In the other instances in which the gangrene had extended so far as to involve the cæcum, I have been compelled to resort to the Lembert silk suture as practised in ordinary intestinal wounds. Dr. Edebohls mentions two cases, one by Dock and one unpublished case, in which leakage and fatal peritonitis followed slipping of the ligature. If we consider the thousands of cases in which the ligature has been used with only, so far as known, two such fatal cases, it does not seem to me to be a very bad record for this method. I believe that the intestines, and in fact all of the organs within the abdomen, should be submitted to the least possible manipulation and traumatism in all surgical procedures. The insertion of sutures or of Dr. Dawbarn's purse-string suture after inversion of the appendix, all require more manipulation than the simple ligature, and in my opinion offer no greater guarantee of safety to the patient. I have never had an accident after the ligature, nor do I know of any accidents which occurred in the work of my colleagues in my long connection with the hospital service in this city. After tying the appendix close to the cæcum where the tissues are sound and removing the diseased organ, I curette the little funnel-shaped portion of the divided appendix which is beyond the ligature, and then thoroughly cauterize it with a mercuric chloride tablet. I again curette the funnel-shaped stump in order to remove any excess of the mercury. The results so far have been such in all cases as to justify my own continuance of this method.

THE RELATIVE INTENSITY OF THE SECOND SOUNDS AT THE BASE OF THE HEART: A STUDY OF ONE THOUSAND CASES.

By SARAH ROBINSON CREIGHTON, M.D.,

NEW YORK.

Most modern text-books on physical diagnosis state or imply that in the normal heart the aortic second sound is louder than the second sound heard in the pulmonary area. The following quotations exemplify the prevailing view: "On account of the more powerful recoil in the aorta, the aortic is the predominating sound."[1] In F. C. Shattuck's book,[2] the matter is stated in this way: "The sound is, in health, somewhat louder and sharper here (*i.e.*, in the second right interspace near the sternum) than it is over the corresponding point in the left side." In Da Costa's "Physical Diagnosis,"[3] we read: "The second sound of the latter" (the aortic valve) "when compared with that of the former" (the pulmonary valve) "is found to be sharper and more accentuated." Musser states that[4] "In health, the pulmonic second sound is not so loud as the corresponding sound of the aorta." Guttman[5] says: "In normal conditions of the heart, the aortic second sound has the same intensity as the pulmonic, or even a somewhat greater intensity." Gerhardt[6] makes a somewhat different statement from any of the above. "Normally," he says, "the second sounds (in the aortic and pulmonic areas respectively) are equal."

In the works on diseases of the heart, I find very meagre statements about the condition of the second sounds at the base of the normal heart, except the following from Bramwell:[7] "The aortic second is louder and more accentuated than the pulmonary"; and from Sansom,[8] who says: "The sound audible in this direction" (*i.e.*, over the pulmonary area) "is normally less intense than that heard on the aortic side." Nearly all the other writers convey the impression that they believe the aortic second sound to be the louder in health; for example, Broadbent[9] writes: "In the pulmonic and aortic areas, accentuation of the second sound is the point especially to be observed as denoting increased pressure in the pulmonic or systemic circulations respectively." Whittaker[10] writes: "A strong accentuation of the second pulmonary sound, in the absence of other cause, may suffice to establish the diagnosis" (of mitral stenosis). Osler makes no explicit statement on the subject, so far as I can see. Cutler[1] says, "The second sound is loudest over the second left interspace or third rib and over the second right intercostal space, both close to the sternum"; and later on in the article, "The pulmonic second sound" (in cases in which the heart has been uncovered by retraction of the lungs) "is often louder than the aortic second." André Petit[2] says: "The reinforcement of the second sound at the pulmonary valve reveals an excess of pressure in the pulmonary circulation, and should put one on the track of some obstacle to the emptying of the left heart, particularly of the auricle in mitral stenosis."

Among books on children's diseases, Rotch and Starr say nothing in particular on this subject. Holt[3] makes a definite statement, namely: "Normally, the loudest of the heart sounds is the first sound at the apex; the weakest sound is the second sound at the aortic orifice." Hochsinger,[4] also, asserts that "in infants and young children the second sound is weaker in the aortic area than in the pulmonary area. It is loudest in the second left intercostal space."

It will be seen that Holt and Hochsinger are the only ones of all these writers who definitely state that the pulmonic second sound is louder than the aortic second sound, in health. All the others record precisely opposite observations, with the exception of Gerhardt, who found both second sounds equal in intensity. The statements of the majority of the writers just quoted are all the more amazing when one observes that, as long ago as 1885, so careful a student as Vierordt proved experimentally that, contrary to the idea of all the writers just quoted, the pulmonic second sound is frequently louder than the aortic second sound in the healthy heart.

Vierordt measured the relative intensity of the different heart sounds in the following manner: Over a given valve area (for example, the second right chondro-sternal articulation) he placed, one after another, layers of gutta-percha of uniform thickness, and noted how many were needed to prevent the transmission of the heart sounds to the ear. Then, by repeating the process over another valve area, he was able to record in quantitative form any difference in the relative intensity of the sounds in the two areas, as measured by the number of layers necessary to obliterate them. These experiments showed that in only five out of thirty-six cases was the aortic sound louder than the pulmonic. Once they were equal. The average results of his estimation were as follows: Between the ages of four and ten years the intensity of the pulmonic second was to that of the aortic second as 7.78 is to 6.26; eleven and twenty years, as 6.60 is to 4.92; twenty-one and forty years, as 5.68 is to 4.81; forty-one and fifty years, as 5.39 is to 5.46.

Möller,[5] using similar methods, found that in twelve cases the aortic second was, on the average, stronger than the pulmonic, the ratio being 2.32 to 2.24. Five of his twelve cases showed an aortic second stronger than the pulmonic second; four cases showed a pulmonic second stronger than the aortic second; in three cases, the aortic and pulmonic second sounds were equal. On the other hand, Schreiber,[1] who worked with Möller and investigated the same number of cases, found that, on the average, the pulmonic second was the stronger (2.25 to 2.07). In nine of the twelve, the pulmonic second was the louder.

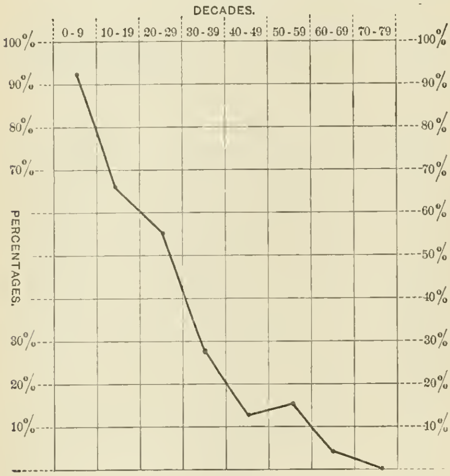

Chart 1.—Showing the Per Cent. of Accentuated Aortic Second Sound in each Decade. Based on 1,000 cases.

Personal Experience.—In view of the discrepancy between the measurements of Vierordt, Schreiber, and Möller, and the statements handed on from one modern text-book to another, it seemed to me worth while to investigate the matter in a considerable number of cases. Accordingly, during the summer of 1899, in Dr. Richard C. Cabot's clinic at the Massachusetts General Hospital, one thousand cases were examined. The cases were distributed in the various decades as follows:

Under 10 years	123
From 10 to 19 years	130
" 20 " 29 "	207
" 30 " 39 "	181
" 40 " 49 "	182
" 50 " 59 "	109
" 60 " 69 "	50
" 70 " 79 "	18
Total	1,000

Among these were 24 cases of general debility, 51 cases of malaria, 63 of gastro-intestinal disorders, etc. The remainder were divided among such affections as the anæmias, neurasthenia, sciatica, etc.

In the 1,000 cases examined, the pulmonic second sound was the louder in 291 cases; the aortic second sound was the louder in 486 cases; while the two sounds were of equal intensity in 223 cases. When we come to examine these figures more in detail, we find that the younger the patient the more apt is the pulmonic second sound to be accented. Thus an accented pulmonic second sound was shown:

Out of	123	cases	under 10	years,	by	111	or	90+	per cent.
"	130	"	from 10 to 19	years,	by	87	"	66.9	"
"	207	"	" 20 " 29	"	"	111	"	53.1	"
"	181	"	" 30 " 39	"	"	51	"	27.6	"
"	182	"	" 40 " 49	"	"	24	"	13.1	"
"	109	"	" 50 " 59	"	"	16	"	14.6	"
"	50	"	" 60 " 69	"	"	2	"	4	"
"	18	"	" 70 " 79	"	"	0	"	0	"
	1,000								

On the other hand, accentuation of the aortic second became more common with each decade. An accented aortic second sound was shown:

Out of	123	cases*	under 10	years,	by	only	4	or	8 2	per cent.
"	130	"	from 10 to 19	years,	by		33	"	25.5	"
"	207	"	" 20 " 29	"	"		72	"	35.5	"
"	181	"	" 30 " 39	"	"		100	"	54.9	"
"	182	"	" 40 " 49	"	"		136	"	74.9	"
"	109	"	" 50 " 59	"	"		82	"	75.4	"
"	50	"	" 60 " 69	"	"		46	"	92	"
"	18	"	" 70 " 79	"	"		17	"	94	"
	1,000									

* In eight the second sounds were equal.

Exhibited in tabular form, these figures give the curves shown in Charts 1 and 2.

In each of these cases the heart was normal, so far as could be determined, and we eliminated all patients having diseases which are ordinarily supposed to alter the heart sounds in any way, except pulmonary phthisis. Nine-tenths of these patients had walked a considerable distance to the out-patient department and were by no means seriously sick, while many of them were healthy individuals, assistants in the clinic, interpreters, or relatives accompanying patients.

Effects of Exercise and Position.—Many were experimented with to ascertain the effects of exercise and position on the second sounds. Exercise does not seem to alter the relative intensity of the aortic and pulmonic second. In a few instances, the aortic was louder in the upright position, while the pulmonic came out with greater force when the patient was lying down.

Accentuation in Youth.—In children under four years, the accentuation at the pulmonary orifice is very striking; between the ages of ten and twenty, it is less so, and from twenty years on, there is seldom any marked difference between the sounds until after the fortieth year, when the aortic second begins to come out sharply.

Tentative Explanations.—Such are the facts. It is, of course, well known that in the fœtus at term the wall of the right ventricle is nearly if not quite equal in thickness to that of the left. From this time on, the thickness of the right ventricle diminishes, until at two years it is often actually thinner than at six months intra-uterine, despite the great increase in the size of the heart as a whole.[1] This fact, viz., the

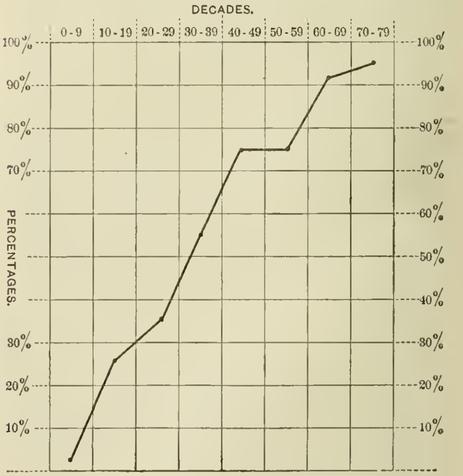

Chart 2.—Showing the Per Cent. of Accentuated Pulmonic Second Sound in each Decade. Based on 1,000 cases.

---

[1] *Ibid.*

[1] Gibson : "Diseases of the Heart and Aorta," p. 8.

relatively great thickness of the right ventricular wall, must be taken into consideration in very young children, and probably assists in accounting for the great accentuation in the pulmonic second sound at that age. It may be further suggested that, in children up to nine years, the accentuation of the pulmonic second, which I have shown to be normal, is to be accounted for partly by the fact that the lungs are not fully expanded before that age. Rotch says:[1] "At what age the lungs reach their full expansion forward has not been determined. It would appear that it is not before five or six years, and it is probably still later." We know that in any disease causing a rise in blood pressure in the pulmonary circulation, such as phthisis, pneumonia, emphysema, etc., we have an accentuation of the sound produced at the pulmonary valves. It seems that the lack of expansion of an otherwise normal lung may well produce the same effect as consolidated tissue. The reason for the pulmonic accentuation from ten years on is not so easy to understand, but whatever the explanation may be, the results of these one thousand cases would seem to show that, up to the time of full physical maturity (twenty-fifth to thirtieth year), the recoil of the blood upon the pulmonary valves is more forcible than that which closes the aortic valves. This difference diminishes progressively with growth until full maturity, when the normal condition would seem to be equality in the recoil of the blood against both sets of valves. We may suppose that this situation holds until degeneration of arteries, and all the many changes which follow the gradual wearing out of various parts of the body, increase the resistance in the systemic circulation. The latter has many more pitfalls to encounter than the pulmonary circulation, especially in the tissues of the kidney and liver, which offer splendid ground for degenerative changes. Autopsies certainly prove that it is rare to find perfect kidneys after forty years of age.

Conclusions.—1. Accentuation of the pulmonic second sound is almost invariable in young children and frequent in youth.

2. After the fortieth year of life, the reverse is the case, and it is then rare to find a pulmonic second sound as loud as the corresponding aortic sound.

3. Between the ages of twenty and thirty years, there is no marked accentuation of either sound.

4. In view of the above facts, it is obvious that when one speaks of an accented pulmonic second sound as corroborative of a diagnosis of heart disease, such accentuation must mean an increase in the loudness of the sound over that normally to be expected at the age of the patient in question. A comparison with the aortic second is not sufficient to settle the question.

5. Further, when we speak of an aortic second sound as accented, we must mean (in case of patients over forty years) more accented than it normally is. Once more, the simple comparison with the pulmonic second sound will not settle the question. The comparison must be with an ideal standard carried in the mind.

6. In interpreting the meaning of an accentuation of the pulmonic second in suspected mitral stenosis, one must bear in mind the age of the patient. The presence of a pathological accentuation of the sound can be determined only in relation to the degree of accentuation which is to be expected at the age of the patient in question.

Erysipelas.—Moist applications of a two-per-cent. solution of creolin frequently cause very rapid subsidence of the inflammation and fever.—M. Wolf, *Wiener med. Presse*, October 8, 1899.

ACQUIRED NON-MALIGNANT STRICTURE OF THE RECTUM: CAUSES, SYMPTOMS, AND TREATMENT.

By W. DUFF BULLARD, M.D.,
NEW YORK.

By the great majority of observers, syphilis has been regarded as the most common etiological factor in stricture of the rectum. No convincing argument, however, has yet been brought forward which proves beyond conjecture that syphilis finds in the rectum structures more readily yielding to its ravages than tissues in other portions of the alimentary canal.

Before proceeding to the discussion of the subject proper of this article, I shall endeavor to give a brief résumé of what has been said by various authors upon diseases of the rectum with especial reference to syphilis as a causative factor.*

White,[1] of Bath, the first English surgeon, I believe, who wrote a work on stricture of the rectum, makes no mention of the venereal poison as a cause of stricture. This is also the case with Mayo[2] and Frederick Talman,[3] and even Mr. Syme, in a paper on diseases of the rectum, does not allude to it. Indeed, it would appear that the earlier English writers have passed over in silence any venereal disease as a cause of stricture. Thus, as early as 1815, Richerand[4] speaks of "condyloms internes" of the rectum. Others have spoken of tubercles in this organ causing stricture, but Bushe[5] says that "neither Morgagni, Desault, Tanson, White, Copeland, nor Calvert say that these tubercles depend on any specific cause." Both Richerand and Delpech, however, assert most distinctly that they depend upon the venereal poison. Bushe, in a short chapter on venereal ulceration of the rectum, says: "This ulceration may arise from the direct application of the venereal poison, or it may coexist with other secondary symptoms." He does not, however, speak of this disease as causing stricture. South,[6] among the numerous causes enumerated as giving rise to stricture, includes that of syphilis, and says: "The immediate cause of stricture of the rectum is always a more or less extensive inflammation or continual irritation of the rectum, in consequence of which there is a secretion of plastic matter, thickening and elongation of tissue."

According to Copeland,[7] Desault saw stricture so frequently in combination with other symptoms decidedly venereal, that he did not hesitate at once to put his patients under a course of mercury, and, he says, with a success that fully warranted him in considering it as very frequently a symptom of the venereal disease. It must be stated here, however, that at the same time Desault resorted to local treatment by means of the bougie. Copeland further remarks that stricture is much more frequent than physicians imagine, and it is not so frequently of a cancerous origin as authors would lead us to believe. Curling,[8] in speaking of chronic ulceration of the rectum, says: "Mr. Avery exhibited a specimen of ulceration of the rectum in a female, the history of which clearly showed the connection of the lesion with syphilis and its probable occurrence as one of the secondary phenomena of the disease. When the patient died she had numerous indelible marks of syphilitic eruption on the limbs and trunk, and was suffering from sore throat." It appears that Mr. Curling is not a believer in the so-called "syphilitic stricture," for when speaking of stricture he remarks "that Desault supposed they were of syphilitic origin, but his observations in reference to that point are not satisfactory." Mr. Quain,[9] while speaking of ulceration and stricture as a result, does not allude to venereal disease as a cause.

---

* For many of the references given in the text, acknowledgment is due to Erskine Mason.

In looking over some of the standard authors on general surgery, I find Chelius[10] includes syphilis as one of the causes of stricture. Erichsen makes no mention of any venereal stricture, but speaks of having met "that form which occurs low down several times in young women otherwise perfectly healthy." The same is true of the works of Fergusson, Pirrie, and Druitt. Gross[11] says: "A syphilitic stricture is occasionally met with in the lower bowel, caused not by any constitutional taint, but by direct inoculation with chancrous matter." Mr. Henry Smith[12] regards this disease as due to constitutional syphilis, and advocates "the exhibition of small doses of mercury and the iodide of potassium" in the treatment of the same. Lancereaux[13] confirms the ideas expressed by Gosselin; and Bumstead[14] is an advocate of the disease being chancroidal and not syphilitic. Berkeley Hill,[15] on the other hand, while giving an accurate description of this stricture, says: "Many observers, among whom is Gosselin, do not regard this as a product of the syphilitic diathesis," but he does not give his own opinion. I infer, however, that he entertains the more modern view in reference to this subject when he says: "In the treatment of syphilitic stricture of the rectum specifics are of little value."

Among the more recent authors I find that Dr. Van Buren[16] regards the chancroid, especially when it takes on a phagedenic character, as the only mode in which any form of the venereal disease is certainly known to give rise to strictures of the rectum. On the other hand, I find Mr. Allingham,[17] in referring to ulceration of the rectum, uses the following language: "I have no doubt that a good many are of syphilitic origin. They may be the result either of secondary or tertiary syphilis, and other syphilitic lesions will be observed; but sometimes the ulceration of the bowel with a syphilitic history is the only symptom present." With reference to stricture of the rectum he says: "I am of the opinion that some strictures are syphilitic in their origin, and when they are, the patients generally do well." For these cases he advocates anti-syphilitic treatment.

Again, Hamilton[18] remarks: "The most common cause of stricture of the rectum in public practice is syphilis and chancroid. At Charity Hospital these cases are constantly under observation, and they are observed to be particularly frequent among women. Gosselin[19] concluded from his observations on twelve patients, all women, that the affection known as "syphilitic stricture" was due to the local sore, "the chancroid," rather than to constitutional syphilis. Mason[20] states that the deductions he would make are: "The disease appears peculiar to females; it occurs chiefly between the ages of eighteen and thirty-five years. The locality of the stricture, as a rule, is between one and two inches from the anus. Anti-syphilitic remedies possess no beneficial influence over the disease. This disease is more frequent than is generally supposed." Though unwilling to deny that a stricture of the rectum might occur as the result of a syphilitic ulcer, he believes that such an occurrence must be exceedingly rare; and, therefore, the term "syphilitic stricture" is an improper name. Hence the disease, being due to the chancroid, should be known as the "venereal," or rather "chancroidal" stricture. He reports thirty-one cases, all in women.

Bäumler[21] states that: "A number of authors look upon 'chancres' as the sole cause of the stricture. Others, among whom are A. Guerin and Verneuil, urge the syphilitic nature of the process upon which the disease depends. Virchow leaves it undecided, since he has had no opportunity to examine the early stages of the process. It must, however, be admitted that secondary ulceration of the rectum may extend upward from affections about the anus, and also that gummata may occur in the rectum. Moreover, if stricture of the rectum is found in young women, it is probably due to 'chancre' cicatrices: if it is met with in old women and men, the inference should be that it is either caused by cancer or by a syphilitic infiltration with its consequences. Only in those cases in which no cicatricial tissue has been formed, *i.e.*, where the contraction is due to the infiltration alone, will the results of anti-syphilitic treatment contribute anything toward rendering the diagnosis more certain."

The "chancres" referred to in the above quotation are evidently intended to mean only the local sore—chancroid.

Cooper and Edwards[22] state that "syphilitic ulceration is most often due to the disintegration of gummatous growths and is therefore connected with the tertiary stage of the disorder." They also state that "a history of syphilis is obtainable in from twenty to thirty per cent. of all cases of stricture of the rectum." In a rapid examination of their book, it was noted that no mention was made as to whether they found stricture occurring more frequently in women or not. The Allinghams[23] say: "In our experience, certainly half of the cases of stricture with ulceration have been syphilitic of a late secondary or tertiary type." No mention of stricture of the rectum occurring more frequently in women is here made, and they do not deign to mention how it is possible to distinguish between a stricture of the tertiary type and one of the secondary.

Matthews[24] says: "I have already stated that I do not hold to the theory of chancroidal ulceration and consequent stricture, as advocated by Ziegler, Mason, Kelsey, Van Buren, Gosselin, and others. Nor do I subscribe to the belief that the stricture is caused by the contraction of the cicatrix of the healed ulcer. . . . I believe that strictures in a syphilitic subject are the result of a syphilitic neoplasm which becomes organized into firm tissue. . . . Indeed, so firm am I in this belief, that if it is a question between cancer and no cancer, and it is decided that it is not malignant, ninety-nine out of every hundred cases will, in my opinion, prove to be syphilitic."

Allingham, in tabulating his cases of stricture, says: "Thus out of the total number of ninety-nine cases of stricture, fifty-two or more were syphilitic."

Matthews, although he mentions many cases of stricture seen in his own practice among women, also attaches no importance to the fact, for he does not anywhere state that women are more commonly affected, as least so far as the writer could see. All the authorities in the same way either ignore this peculiarity in the etiology, or state that it is simply a disease of women, and rest their argument there. It seems curious to the writer that so many observers should pass over this peculiar feature with so little reference, and continue along the lines laid down, when the facts in the case do not warrant such a course.

Kelsey says: "Of the existence of syphilitic ulceration of the rectal pouch occurring in the late secondary or tertiary stage of the disease, there can be no more doubt than of the existence of the same condition in the fauces or trachea. . . . I believe it to be a rare condition . . . and one that in no way accounts for the condition of hypertrophy of the surrounding tissues and stenosis so commonly described as 'syphilitic stricture' of the rectum." Again, quoting Fournier's description of the so-called ano-rectal syphiloma, he says: "The disease commences as an infiltration of the rectal wall by the neoplasm; the deposit is entirely submucous and occurs by preference in the rectal pouch, and always encircles the whole calibre. . . . There is no contraction and no ulceration until later. As the deposit increases in amount, the mucous membrane over it loses its vitality and becomes ulcerated, and the deposit itself finally degenerates into fibrous tissue, retracts, and causes stricture."

Such a process as Fournier describes is unknown in any other part of the body, and equally unknown as any process characteristic of syphilis. Nor is it in any way amenable to anti-syphilitic treatment, the condition being simply a chronic hypertrophic proctitis independent of syphilis. The weight of evidence is decidedly in favor of the possibility of the causation of stricture by phagedenic chancroids; but that any large proportion of strictures are in any way due either to chancroids or syphilis has never been proved, while recent clinical and microscopical study is all against this time-honored theory. The views of Dr. Kelsey are, in the opinion of the writer, not sufficiently radical. The author would go still further and say that not one in a thousand cases of stricture is caused either by chancroid or syphilis, and that what Dr. Kelsey designates "chronic hypertrophic proctitis" can be explained frequently, not as the effect of inflammation starting in the rectal wall, but as the direct result of some mechanical cause external to the rectum and encroaching upon its calibre.

After reviewing the writings of the many authors above referred to, it would seem that no two of them agree as to the frequency with which syphilis and chancroids act in the production of stricture of the rectum. All are, however, of the opinion that the disease is more frequent in women.

In the writer's opinion, the primary syphilitic lesion occurs in the rectum only in victims of passive pederasty or by means of direct contagion. There is very little destruction of tissue produced by a chancre, and the tendency is for it to run its course to spontaneous healing in from four to six weeks. Mucous patches may also occur in the rectum as a secondary manifestation of syphilis. As is well known, the fauces and pharynx are the parts most frequently affected by this type of the disease. The symptoms here are more aggravated by irritants, such as tobacco, alcohol, etc. Men are more subject to these irritations. Why should the female rectum be the structure in which the mucous patch proceeds to stricture, while the male organ escapes? Mucous patches in the fauces produce decided symptoms. Let the syphilographer tell us how many patients suffer from symptoms of ulcerated mucous patches in the rectum at this stage of syphilis. The writer believes their answer will be that no case showed symptoms of rectal disease which were not present before the syphilis was contracted. But if we admit that mucous patches occasionally do occur in the rectum, will they cause stricture of the rectum without first presenting well-marked symptoms of acute ulceration with its muco-purulent discharge and tenesmus? No. The mucous patch is distinctly an ulcerative lesion, and rarely extends deeper than the mucous membrane, and always responds to cleanliness and anti-syphilitic treatment. These rectal strictures, however, do not respond to anti-syphilitic treatment at any stage of their development.

Most authorities look upon tertiary lesions and the ano-rectal syphiloma of Fournier as the cause of most non-malignant strictures of the rectum. The ano-rectal syphiloma is supposed to be a diffuse infiltration of all the lower part of the rectal wall, causing an hypertrophy which narrows the canal. Such a process occurs, but it is, in the writer's opinion, neither caused by, nor characteristic of, syphilis. In his opinion, it is due to prolonged irritation acting in the rectum, or more frequently to external causes, such as will be subsequently described under the head of stricture from cellular deposit.

Several authorities claim to have seen gummata as circumscribed swellings in the wall of the rectum; but, if such is the case, the writer can see no reason why such deposits in this locality should not as readily respond to anti-syphilitic treatment as they do in other parts of the body. However, authorities state that they do not respond to specific treatment. Therefore the author believes it is safe to say that no lesion in the body is syphilitic that does not respond to specific treatment. Furthermore, he is convinced that syphilis *per se* is not a causative factor in stricture of the rectum. The more frequent occurrence of stricture in the female rectum can be accounted for by reason of the greater liability to traumatism to which the latter is exposed. Every coitus and every pregnancy affect the rectal wall, and every inflammatory process in uterus, tubes, or ovaries may exert a pernicious influence.

The author is of the opinion that the great majority of observers have been led to consider syphilis the causative factor in the production of rectal stricture by the fact that this condition has been most frequently observed in syphilitic subjects. To the author's mind it appears much more rational to assume that syphilis is not immediately responsible for such lesions for the following reasons:

Endarteritis is a well-recognized state in syphilis. This change in the vascular system, combined with the resultant low state of nutrition, renders the mucosa of the rectum less resistant to irritants and trauma. Under these circumstances, small losses of the epithelial covering, which would readily be restored in healthy individuals, remain unhealed and constitute the beginning of simple inflammatory or ulcerative conditions. Examples of this are offered in the indolent healing of wounds and in the delayed union of fractures in syphilitic subjects.

The production of a stricture of the rectum is characterized by a progressive narrowing of the lumen of this viscus. The varieties of lesions that tend to produce such a condition may be divided into two large classes:

I. Lesions external to the bowel, producing mechanical obstructions and circulatory disturbances resulting in involvement of the rectal wall.

II. Lesions originating in the wall of the bowel itself.

Lesions external to the bowel operating to produce rectal stricture are of more frequent occurrence in the female than in the male subject.

This is undoubtedly due to the fact that in the former the rectum lies in closer proximity to the organs of generation, which are more subject to radical changes than in the latter. Disease of the vulva or vagina, as manifested in the cicatricial contraction following old non-syphilitic ulceration, chancroidal disease, extensive gonorrhœal inflammation, and, most common of all, traumatisms, as illustrated by the ruptured perineum, directly affect the rectal wall. Enlargement of the uterus in pregnancy or any disease of the adnexa, if allowed to progress, interferes with proper performance of the rectal functions. Pressure is exerted upon the elastic rectal wall, thereby producing a rounded spur which projects into the lumen of the bowel. If there be added to this a constipated habit and the straining necessary to force the hardened fæces beyond this spur, the continuity and integrity of the rectal wall are menaced. This condition, if unrelieved, obstructs the circulatory efforts of nature which are essential to the sustenance of the mucosa. The mucosa gradually loses its elasticity and vitality, until, by constant irritation, the stools erode the epithelium covering the spur. Ulceration now takes place, and the steps between this stage and stricture of the rectum are short.

This sequel can, perhaps, most frequently be observed in patients suffering from adherent retroflexed uterus; but it may also result from the action of any mass encroaching upon the normal calibre of the rectum. Nature, apparently realizing the dangers to which the rectum is exposed, endeavors to overcome them by dilating the canal into what is called the "rectal pouch." If, however, this "rectal pouch" is surrounded by a plastic exudate from a contiguous pelvic peritonitis, cellulitis, peri-prostatic or pelvic abscess, the power of adapting itself to the mass of fæces is lost. Under these circumstances the pressure necessary to push a stool beyond the obstruction may be likened to an attempt to force semi-fluid material through an old stiffened section of rubber hose having a partial kink in its calibre. Dilatation occurs above the kink until sufficient pressure is exerted to force a passage or to burst the tube. The inflammatory deposit may so interrupt peristaltic action as to give rise to obstruction.

Stricture resulting from such a condition is likely to consist of an hypertrophy of all the walls of the bowel for three or four inches above the point where the lumen of the gut is encroached upon by the inflammatory deposit. This results from Nature's efforts to force the contents of the rectum through the adherent and obstructed portion of the bowel. Later, when dilatation results from constant pressure above, ulceration and pocketing occur. This, however, is observed only in those well-advanced cases in which treatment had not been applied or in which the real trouble had not been recognized.

Chancroids frequently occur at the anal margin and cause fissures and ulcers about the anus. The author, however, does not believe that they are the cause of stricture except in those cases in which the action of the sphincter is impaired or in which they are allowed to progress to the phagedenic type, and the induration that follows such an extensive process causes a migration of leucocytes into all the neighboring tissues that later become organized into firm tissue. The function of the rectum is to expel all irritating substances and not to draw them in. If chancroidal poison was carried directly into the rectum we surely would find that nearly every prostitute had a stricture of the rectum.

II. Lesions occurring in the rectal wall.

Tuberculosis is sometimes the cause of stricture of the rectum. The rectum is rarely the primary focus of the disease, but when the system is lowered by tuberculosis of the lungs or the like, the bacilli find a locus resistentiæ minoris in the peri-rectal tissue or in the folds of the mucous membrane itself. If they lodge in the peri-rectal tissue, a tuberculous abscess is formed with subsequent ulceration and stricture. If the mucous membrane is first involved, then ulceration at once begins and spreads rapidly, leaving areas of hard indurated and granulating tissue. This ulceration is most intractable to all forms of treatment, and the infiltration of the rectal wall results in a wide, dense stricture composed of fibrous bands, and large areas the seat of ulceration. The diseases of the colon, such as dysentery, typhoid, amœbic colitis, etc., produce ulceration in the rectal wall as elsewhere in the alimentary tract. These ulcerations may not heal readily, and a fibrous stricture results.

He also believes that gonorrhœa exerts no influence in the formation of stricture of the rectum except from direct contagion.

Hemorrhoids is a lesion that exerts the most potent influence. These varicosities, when they become engorged, inflamed, and strangulated, obstruct the passage of stools. They may slough off the surrounding tissue. The ulcer thus left is generally at first superficial and of little consequence; but if left neglected it gradually extends through the whole mucous membrane to the submucous layer of the rectal wall. A partial stricture is likely to result from subsequent cicatrization.

Abscess and fistula in ano are the most common diseases of the rectum. Abscesses usually press upon the rectal wall, as is shown by the excruciating pains suffered by the patient at stool. If the abscess ruptures externally, then small damage is done to the rectal wall. If the abscess discharges internally, a marked ulceration occurs about this opening from the irritation of the infective material carried over its surface by the fæces. Granulation of the abscess cavity takes place and frequently results in the formation of a large, soft mass of exuberant granulations protruding into the rectal calibre. This mass causes a necrosis of tissue in that part of the rectal wall contiguous thereto. These strictures are soft, prone to hemorrhage, and easily dilated under appropriate and judicious treatment.

Prolapse of the rectum, especially when it originates in childhood, tends to narrow the rectal canal as the result of the thickening of all its walls incident to its repeated fall and reduction, and thus causes stricture.

Surgical operations within the rectum and in the neighboring tissues are quite a common cause of stricture of the rectum. Many such cases are reported from all types of operations; perhaps the most common are those following surgical interference in hemorrhoids and fistula in ano.

During the past winter the writer saw two such cases. One, a woman operated upon for hemorrhoids six years before at a large New York hospital (probably Whitehead's operation was done) showed absolutely no sphincter, the anal orifice being a square opening with no contractile power whatever. Two inches up in the rectum a fibrous stricture was felt and then seen through a speculum. Dilatation was not attempted, as the patient, when first seen, was suffering from an acute attack of obstruction. At the subsequent operation, the stricture was found to extend upward into the bowel for five inches. The whole stricture was divided posteriorly and the wound packed after irrigation and cleansing of the bowel. The recovery was uninterrupted. Several details of interest in this case will be reported in a later article. The second case occurred in a man who consulted a well-known (so-called) rectal specialist of New York City. This gentleman injected some fluid into the rectal wall for the cure of hemorrhoids. A slough and ulceration followed, and the patient, becoming dissatisfied with the way he was progressing, forswore all physicians after six months of treatment. Eighteen months later, he was frightened at his condition and called at my office. He presented an easily dilatable stricture, giving to the touch the feeling of a number of hard polypoid masses surrounded by soft, friable tissue. This condition improved greatly under dilatation and local applications.

Pessaries, glass enema tubes, a fall upon the buttocks, bones, pins, and foreign bodies of various kinds that have become impacted in the rectum, are all likely to cause ulceration and subsequent stricture.

The symptoms occasioned by stricture of the rectum can be discussed in two classes: I. Before ulceration occurs. II. After ulceration occurs.

I. Stricture of the rectum presents very few symptoms before ulceration takes place. Alternating constipation and diarrhœa, a sensation of fulness in the abdomen and of weight in the pelvis, may be all that is present. Every physician should feel that such a condition, not responding to the usual treatment in such affections, is sufficient to call for a careful and thorough rectal examination. Occasionally a patient will not present even so many symptoms as above mentioned. The only trouble that would attract attention to the rectum as the cause of difficulty may be a slight throbbing pain at the anus and a feeling of nausea after a stool.

The stools of a patient suffering from stricture of the rectum are necessarily different in character from those occurring in the healthy subject. They usually consist of small, hard, rounded lumps of fecal scybala not unlike a number of grapes separated from the common stalk. The so-called "ribbon-shaped" stools are rarely seen, and then only in those cases in which the stricture is at the anus or is forced down to it by the act of straining. They are of little diagnostic value, as they may be caused by a spasmodic contraction of the sphincter when no stricture is present. As the stricture becomes dense, and the tissue organized into fibrous bands, the symptoms become more severe. There are now distention of the abdomen, impairment of digestion, eructation of gases, and distress after eating. Fecal masses can be felt in the transverse and descending colon. The patient now begins to suffer from tenesmus, and is obliged to go to stool time after time to pass but a few lumps of fecal matter and an excessive amount of muco-purulent material from the irritated mucous membrane of the bowel. The fecal masses begin to act as foreign bodies and cause a catarrhal inflammation of the whole intestinal canal with its attendant mucous discharge and septic absorption.

Relief is temporarily obtained from the use of cathartics, but the process repeats itself again and again, exhausting alike the patient and the intestinal functions. If the patient becomes constipated, acute obstruction may occur and a fatal issue result, unless operative interference is at once instituted. This is more likely to occur if the stricture is in the sigmoid or high up in the rectum, where the intestine may twist upon itself in its peristaltic efforts to push the obstruction onward, than if it is low down in the rectum where all the force is concentrated upon a mass held steadily in position by the surrounding organs and a tight meso-rectum.

II. After ulceration begins.

As a rule, the writer believes that ulceration is the first step in the production of a stricture of the rectum, and consequently cases with as obscure symptoms as detailed above are the exception and not the rule.

The symptoms of ulceration of the rectum should at once attract the attention of the physician. Pain, muco-purulent discharge, and tenesmus are characteristic. The patient is called to stool any number of times in twenty-four hours, to pass only a few scybala surrounded by a quantity of slime and muco-purulent material streaked with blood. If the patient consults a physician when these symptoms are first noticed and proper treatment is instituted, most patients should be cured, and the sufferer escape from the formation of stricture of the rectum. Only too frequently, I fear, the general practitioner prefers to temporize with a serious condition that needs the care of a specialist as much as does a new growth of the larynx. An ulcer of the rectum will rarely respond to internal treatment, even if it be supplemented by the use of an occasional suppository. Treatment locally to the diseased area, and that alone, is essential. A few additions to the physician's regular armamentarium and some training should suffice to render local treatment of an ulcer of the rectum possible in every physician's office. The result should be nearly as satisfactory as is the treatment of an ulcer anywhere upon the limbs or body, instead of being a "bête noire" as now. The writer believes that, could the general profession realize the importance of local treatment and apply it in ulcer of the rectum, non-malignant stricture of the rectum would become a rare condition, instead of a comparatively common one as it is to-day. If the ulceration is neglected, it gradually extends, the symptoms grow more severe, and the patient becomes exhausted from the constant drain on the system and the tenesmus. Nature endeavors to remedy the evil, and cicatricial bands and inflammatory deposit narrow the rectal calibre. Then appear the symptoms of deranged intestinal functions, the abdominal soreness and pain, distention, eructation of gases, nausea, occasional attacks of vomiting, localized areas of peritonitis surrounding the diseased mass, chronic obstipation and septic absorption, until the patient succumbs to acute obstruction or exhaustion.

The presence of stricture of the rectum can easily be discovered if the physician understands the use of the numerous instruments at his disposal. The Kelly tube and Kelsey's modification of the same can be used to explore for stricture as high as the middle of the descending colon. Great care should be taken not to attempt to force any instrument by an obstruction. The instrument should be removed and an attempt made to pass a soft-rubber bougie. It is better at first to use a large size, a No. 8 or 10. This large size will distend the folds of mucous membrane. If this soft instrument seems to catch, some soap-suds or olive oil should be injected through the opening in the centre of the bougie, and another attempt made very gently to pass the bougie onward. If resistance is still met with, there is very good reason to believe some obstruction exists. The bougie should be removed and notice taken how many inches of it were introduced before the obstruction was reached. A Kelly tube may then be introduced about the same distance as the bougie, its obturator removed, and with the assistance of an electric head-light the distal end of the stricture can easily be observed, and its calibre accurately measured. A hard-rubber olive-headed bougie on a small flexible metal stem can then be introduced through the tube directly into the lumen of the stricture. It is not desirable for diagnostic purposes to force a large size through the stricture. It is safer to pass one that is nicely adjusted to the lumen of the stricture. By this means the depth of the stricture and any excessive narrowing of its calibre higher up can readily be determined. The resistance to the return of the bougie after it has passed the upper limit of the stricture determines its proximal end as readily as in the case of a urethral stricture. With some experience, the operator can detect the exact nature of the stricture, whether of a dense fibrous type or of partially organized tissue with an excessive amount of ulceration. The metal stem on the bougie employed by the writer is very small. As soon as the olive head has been introduced into the stricture, the walls of the stricture can be perfectly viewed through the tube as they are gradually distended by the onward passage of the bulbous head.

The treatment of these strictures should be governed by the peculiar conditions present in each individual case. When the stricture is found to be quite wide and thick and of large calibre, with considerable ulceration, the treatment should be directed toward curing the ulceration.

Stimulating, cauterizing, and protective applications should be made directly to the ulcerating areas. Healing will usually attend the conscientious and skilful use of such applications. The inflammatory deposit about the stricture, which is constantly increased by the irritation of infective materials upon the ulcers, will begin to be absorbed, and the bowel wall will become less rigid and more amenable to gradual dilatation. As soon as the irritation is overcome, nature will cause the disappearance of a surprisingly large amount of this partially organized material. Just in proportion to the physician's success in overcoming this irritation and infiltration of tissue is the prognosis good or bad. The longer the duration of the disease the more fully organized the tissue will be, and the less will it respond to the efforts of nature to absorb it. The prognosis, then, in an old case should be guarded as to complete or rapid recovery. The author believes that the vast majority of cases in which the patient is not already suffering from chronic obstruction, when first seen can be made more comfortable by the above briefly outlined treatment than by any operation at present at our disposal. When the disease has progressed to such an extent that the stricture is of a very narrow calibre, the patient greatly reduced and suffering from chronic obstruction, radical treatment is at once demanded. Here, operation is the lesser of two evils.

There are several classical methods to relieve these advanced cases.

The operation known as posterior proctotomy is the most generally useful. This operation consists in an incision made in the posterior wall of the rectum from the upper limit of the stricture backward and outward, dividing all the tissues involved in the stricture, including the sphincter and all the cellular tissue between the rectum, the coccyx, and the external gluteal fold. Such an incision is best made in the median line behind. The bowel should then be thoroughly irrigated with some mild solution until the greater part of the fecal masses in the rectum and colon has been entirely removed. The wound is then tightly packed with sterile gauze. The extensive oozing may be controlled by using very hot irrigating fluids, and careful packing of the entire wound cavity. The care of these cases after operation is by far the most important part of the treatment. Any surgeon can make an incision through the rectal wall, but how to treat the incision afterward so as to get the best possible result does not seem to be thoroughly understood. Much of the benefit to be derived from the operation is lost by permitting rapid healing, as, unless that part of the incision that is expected to form a portion of the bowel passage is not covered with mucous membrane, the contraction of the cicatrix will overcome the best efforts to preserve the calibre of the bowel as large as was intended. In other words, every means at our disposal must be employed toward extensive production of mucous membrane.

Granulation from the bottom and sides of the incision should be prevented as much as possible while the slow-growing epithelium-covered mucous membrane extends down over the sides of this incision to meet that of the opposite side. If the mucous membrane will grow on this cellular tissue which constitutes the bottom and sides of the incision, much will be gained, as there is practically no contraction after this form of healing. So it is desirable to have this wound heal not by primary or secondary union, but by third or last union.

The after-treatment of a typical case will be briefly described. Twenty-four hours after the operation the gauze packing is all removed, great care and gentleness being observed in order to avoid hemorrhage, and the bowel thoroughly irrigated with solution of bichloride of mercury 1 : 10,000, at about the temperature 110° F. This should run into the bowel from a douche bag at the height of about four feet above the patient. The irrigation should be kept up until the return flow is clear. One-half the amount of gauze taken out is then replaced with fresh gauze covered with sterile vaseline and placed in the incision. This is allowed to remain *in situ* for twenty-four hours, and is then removed and a smaller amount replaced. The bowels are not moved for three days; then a half ounce of licorice powder is given to soften thoroughly the fecal mass. When the bowels are inclined to move a large soapsuds enema is given, so that no irritation will be felt by the patient when the mass passes through that part of the bowel presenting only a raw surface. After the bowels have moved satisfactorily the patient is allowed to get out of bed and to return to his home when his general condition warrants the exertion. The stools are kept soft by any laxative, and a daily movement is induced. Directly after the movement, the bowel should be carefully irrigated with the antiseptic solution as already mentioned.

The real work on the case now commences. The patient should be seen in the morning after the irrigation, and the condition of the wound carefully inspected by speculæ and artificial light. Granulation will probably have already commenced. The encroachment of this process on the calibre of the bowel opening must be stopped. It can be controlled by light cauterization with the electric cautery, preceded by an ethyl-chloride spray or by a two-per-cent. solution of eucaine "B," applied on a camel's-hair brush. If the granulating areas are not extensive, covering the wound cavity with bismuth subnitrate or any other inert dusting-powder will accomplish the same result. Along the edges of the mucous membrane, great care must be observed in no way to arrest its growth by too free cauterization. This process should be supplemented by stimulating applications to the edges of the mucous membrane if there is any delay in its growth.

The anterior wall of the bowel, if it has been the seat of ulceration and cicatrization, must also be treated, and any further spread of ulceration or contraction prevented by the use of applications and bougies. As a rule, from six weeks to three months are needed to heal this wound properly. At the end of that length of time, the patient should be nearly cured, but about once a month before retiring the patient should introduce a soft-rubber bougie that has been fitted to the rectum and allow it to remain in place all night. This bougie must not be passed oftener than once a month, or it may cause some inflammatory action which will start the ulceration afresh.

Another method is forcible divulsion of the strictured tract by any of the powerful specula and dilators at our command. This method is mentioned only to be condemned as dangerous and unsurgical. It is impossible to tell how far the effects of such a divulsion may go. It may tear through the wall of the rectum into the cellular tissue and a septic peri-proctitis result, or the tear may extend into the peritoneum and a septic cellulitis or peritonitis result in the premature death of the patient.

If the local disease is so far advanced as to contraindicate an attempt to bring about a cure of the local trouble, the descending colon can be opened either in the left inguinal or lumbar region, constituting the operations known as left inguinal or lumbar colostomy. Either of these operations will give immediate relief to the sufferer. It is not my purpose here to give a description of these operations, as they have been fully described in numerous works on general surgery, as well as in several works devoted entirely to rectal diseases. It will be sufficient to state that a very good technique for the inguinal operation (the preferable) can be found in the "Twentieth Century Practice of Medicine" or in Dr. Kelsey's book, "Surgery of the Rectum, and Pelvis."

Briefly summarized, the conclusions the author would draw are:

1. The majority of rectal strictures are of non-syphilitic origin.

2. Syphilis may be a predisposing, but it is not an immediate, cause of stricture of the rectum.

3. Trauma is the chief immediate causative factor in the production of rectal stricture.

4. The proper and intelligent local treatment of non-syphilitic ulceration of the rectum will minimize the occurrence of rectal stricture.

POST-PARTUM HEMORRHAGE, ITS PREVENTION AND TREATMENT, WITH THE REPORT OF AN UNUSUAL CASE.

By EDWARD P. DAVIS, A.M., M.D.,

PHILADELPHIA, PA.,

PROFESSOR OF OBSTETRICS IN THE JEFFERSON MEDICAL COLLEGE AND IN THE PHILADELPHIA POLYCLINIC; OBSTETRICIAN TO THE JEFFERSON, PHILADELPHIA, AND POLYCLINIC HOSPITALS, ETC.

In spite of recent advances in modern obstetric science, post-partum hemorrhage remains one of the great dangers to the parturient woman. Asepsis protects her from the invasion of disease, but in post-partum hemorrhage we have a source of morbidity and mortality that often brings the patient into great danger with but little warning.

We must recognize as the most frequent cause of post-partum hemorrhage the patient's exhaustion. This is of two sorts, local and general. The local exhaustion which threatens her with bleeding is seen in the relaxed condition of the uterus. The general exhaustion which underlies the local condition is observed in those cases of protracted labor in which the mother fails to expel her child spontaneously. Less frequent causes of post-partum hemorrhage are the retention of a partially detached placenta or of a portion of the placenta and membranes within the uterus, lacerations of the genital tract which open blood-vessels, and a profoundly altered condition of the patient's blood.

The prevention of post-partum hemorrhage calls for the careful avoidance of exhaustion. This can be effected only by a thorough examination of each patient before labor or in the earliest stages of labor, to ascertain the presence or absence of an insurmountable obstacle to delivery, and to recognize if possible any complicating condition which may render the labor unusually long and difficult. Much has been said regarding the value of palpation and auscultation in diagnosis, making vaginal examinations infrequent, and thus avoiding septic infection. In the same way very much may be done to avoid exhaustion and hemorrhage if an accurate examination is made before labor, ascertaining the relative size of mother and child, the position of the child and its presentation, the position of the placenta, the muscular vigor and development of the mother's uterus and general muscular system, and the presence or absence of abnormal distention of the uterus through multiple pregnancy or polyhydramnios. We cannot too strongly insist upon the fact that to be forewarned is literally to be forearmed in the prevention and treatment of post-partum hemorrhage.

The complications recognized as predisposing to hemorrhage must each be met in its appropriate way. In the case of marked disproportion between the pelvis and the probable development of the child, induced labor furnishes the practitioner with a safe method of delivery. If the womb be over-distended by multiple pregnancy or by excessive fluid, the physician will leave instructions with his patient that he be summoned early, and will take care to avoid the rapid emptying of the uterus. If the mother's general muscular system and uterus are deficient in tone, she may take appropriate tonics during pregnancy, and during labor the physician will be on his guard to prevent exhaustion.

In dealing with the more unusual causes of post-partum hemorrhage, considerable difficulty is at times experienced. In syphilitic patients we expect a partially adherent placenta, which, becoming but partially detached, gives rise to hemorrhage at labor. In a patient who has had gonorrhœa during pregnancy, adhesion of the membranes may cause slow dilatation and interfere with the prompt and complete emptying of the uterus. If a patient be seen early in her pregnancy, and if we find her the victim of malarial poison, of profound toxæmia, or of specific disease, we may, by the liberal use of iron and arsenic, so improve the condition of the blood as entirely to avoid post-partum hemorrhage. Each case of pregnancy and labor demands its individual study, and no case can be successfully treated without considering the prevention of this important complication.

In the conduct of labor, much can be done to avoid hemorrhage. It is well, if possible, to locate the placenta. This may be accomplished by palpation and auscultation, and should a suspicious oozing of blood occur, a thorough vaginal examination should be made immediately, the hand being introduced as far as possible toward the brim of the pelvis.

Remembering that exhaustion is the great cause of bleeding, the patient's strength must be carefully preserved. During the first stage of labor, she should receive liquid food in small quantities, as frequently as she can take it, and, if necessary, stimulus as well. Loss of sleep during the first stage of labor must be reduced to a minimum by the use of appropriate sedatives. Gr. x. of hydrate of chloral given in syrup and water, either by the mouth or by the rectum, may be repeated three times at hourly intervals to advantage in many cases. In other patients, gr. xx. of bromide of ammonium gives good results. In other patients, gr. x. of trional taken with broth, soup, or with a tablespoonful of whiskey in hot water, causes several hours of refreshing sleep. Care should be taken that the bladder and rectum be frequently emptied, that unnecessary irritation of the bladder and delay in labor may thus be avoided. A warm bath at the beginning of labor often lessens the irritation and pain which the patient suffers. An experienced nurse will carry her patient through the first stage of labor in good condition by those arts of nursing which conduce so much to her comfort. Obstetric nurses should be trained to utilize the best postures for patients during this stage of labor, and thus suffering may be reduced to a minimum.

A prolonged first stage of labor must occasion anxiety to the physician. He must assure himself that no insurmountable obstacle to the birth of the child is present. If dilatation of the cervix seems practically impossible without assistance, he will find the use of an elastic rubber bag filled with antiseptic fluid of the greatest advantage. I employ most frequently McLean's double bag, because it affords us the greatest amount of dilatation with but one insertion of the bag. By filling one half of the bag at first and then the other from one to two hours later, we obtain, in from two to three hours, a practical dilatation of the os.

During the second stage of labor, especial attention must be given to maintaining the general strength of the patient. She should be placed in such a posture as to favor the mechanism of labor. While the head is passing through the pelvic brim, in cases in which the back of the child is directed to the left side of the mother's pelvis, she should lie upon her left side. In second positions, when the back is toward the right side of the mother's abdomen, the patient should lie upon her right side. When the head has reached the pelvic cavity and is coming down upon the pelvic floor, patients sometimes do better in the semi-sitting posture, resting the body upon the tuberosities of the ischia and bending the trunk forward, while the hands grasp firmly the back of a chair placed in front of the patient. In some cases of difficult labor, we have succeeded by placing the patient upon a padded slop jar, the trunk of the body bending forward.

The decision to interfere during the second stage of labor requires careful observation and good judgment. Thanks to aseptic precautions, it is undoubtedly at the present time safer for the patient to interfere during the second stage of labor as soon as her expulsive powers show signs of exhaustion. I call attention to the phrase "signs of exhaustion" as distinct from an exhausted condition itself. It is the duty of the practitioner not to allow the patient to become exhausted. We have formerly been taught that the head of the child must remain two hours upon the pelvic floor before the use of forceps is justifiable. It is, however, impossible to make a hard and fast rule for these cases, and I have no doubt that many patients have suffered from exhaustion and hemorrhage because of too long delay through some arbitrary standard. When the head has reached the pelvic cavity, the membranes having ruptured, the cervix being fully dilated, and the presentation and position favorable for the use of forceps, delay must not occur.

The instrumental termination of labor must usually be conducted under anæsthesia, and here a choice and method of administration of the anæsthetic have an important bearing on post-partum hemorrhage. For the use of forceps, I distinctly prefer ether. Deep anæsthesia is never necessary in the use of forceps, and while the patient should be sufficiently under the anæsthetic to be insensible to pain and to relax her limbs, she should never be in the semi-asphyxiated condition often observed in prolonged operations under ether. The administration of ether for the use of forceps demands as much skill and care as does the administration of ether for the removal of an ovarian cyst. It is a tribute to the faithfulness and care of practitioners that so few accidents from anæsthetics occur in obstetric practice. But the burden of responsibility thus often assumed by the practitioner alone is excessive and unjust alike to him and to his patient. Whenever possible, the anæsthetic for the termination of labor should be given by a thoroughly competent person, and one who will follow down the uterus with the hand during delivery, and who understands the manipulation of the womb necessary to prevent relaxation and hemorrhage.

When the physician has determined to end labor instrumentally, he must consider the possible traumatic lesions which may expose his patient to the dangers of post-partum hemorrhage. He may naturally raise the questions, "Shall I allow the patient to recover from the anæsthetic and to expel the placenta spontaneously, or shall I immediately remove the placenta before the patient fully rouses? If lacerations occur, shall I not be in a better position to repair them if I empty the womb completely and repair lacerations before the anæsthesia is entirely removed?" In this regard, I believe that the safest course is, after the delivery of the child, to continue the anæsthesia in a partial degree, allowing the patient to rouse and become partially conscious and to assist in the expulsion of the placenta. This may be done without loss of time, and the result is usually satisfactory. So soon as the child is delivered, the anæsthetist remains with the patient ready to administer the ether again. Having cleansed his hands, the physician in charge, compressing the uterus gently as the patient wakes and rouses, may urge her to bear down, and in from ten to twenty minutes after the birth of the child, the placenta may readily be expressed by Credé's method. When this has been done, the physician should determine whether or no laceration of the cervix accompanied by hemorrhage is present. In suspected cases, it is well to introduce a speculum with tenaculum forceps and to examine the cervix. In some cases, digital examination of the cervix will detect the presence of a laceration sufficiently great to demand suture. If there be no such laceration, the pelvic floor and perineum must next be subjected to scrutiny. If it is necessary to take stitches, enough ether may be administered to the patient to make her controllable, and the suture be immediately performed.

Before the insertion of the suture in the pelvic floor and perineum, if relaxation of the womb is threatened, it will usually become apparent. The womb will fail promptly and vigorously to contract, the patient will have a greater flow than is natural after childbirth, and the physician may be in doubt as to whether or not hemorrhage will occur. I believe that the interests of the patient are best served by taking all possible precautions against hemorrhage when a doubt arises. In such cases, therefore, I am accustomed, upon the appearance of relaxation of the womb, immediately to douche the uterus thoroughly with hot salt solution or with boiled water only, and to tampon it with iodoform gauze. I have yet to observe a case of infection which could be traced to this manœuvre, and I have yet to be disappointed in it as a means of assisting in the prevention of hemorrhage. So soon as this is done, the patient should receive a hypodermatic injection of gr. $\frac{1}{15}$ of sulphate of strychnine. After this, lacerations in the pelvic floor and perineum may be repaired under anæsthesia, giving as little ether as possible, but holding the womb to prevent its relaxation.

As soon as the patient has recovered from the anæsthesia sufficiently to swallow, ʒ ii. of fluid extract of ergot should be taken by the mouth, or, if the patient is nauseated, an injection of ergot should be made beneath the skin. It is possible to obtain for this purpose aseptic ergot which can be readily injected and directly absorbed. To control the womb, the physician must remain beside his patient, holding the uterus firmly, but not fatiguing the uterine muscle with unnecessary and useless manipulation. In grasping the womb, care should be taken that pressure is exerted upon the anterior and posterior walls, and that the tube and ovary are not included in such compression. Pressure should always be avoided upon the fundus of the womb, for inversion of the uterus with its dangers has followed the "dimpling" of the fundus. Under the treatment described, the patient usually reacts from labor in a satisfactory condition, the uterus remaining well contracted, and shock and relaxation of the womb being avoided. Should these measures, however, not be entirely efficient, gr. $\frac{1}{30}$ sulphate of strychnine with gr. $\frac{1}{200}$ of atropine may be injected. The injection of ergot may also be repeated, or ergot may be administered by the mouth. The patient's head should be kept low, and if the pulse is lacking in volume, a rectal injection of freshly made coffee, well diluted, will be found of advantage. As soon as the danger of relaxation is past, if the physician fears its recurrence, the nurse may apply compression to the uterus, using three towels made into firm rolls eight inches long and three inches in diameter. The womb should be brought by the hand downward and forward, one of these rolls being placed above the fundus and one on either side, and the usual obstetric binder applied from above downward.

It is, however, exceedingly important that a patient threatened with hemorrhage should not be left by her physician while the danger exists. It is the duty of her attendant to be sure that she has fully reacted from delivery, that the pulse is slow, its volume good, its tension good, the womb contracted, and the general condition of the patient satisfactory, before she can be left to the care of the nurse alone.

As regards the further treatment of such a case, the external parts are kept scrupulously clean and disinfected with bichloride of mercury 1 : 4,000 after each emptying of the bladder or rectum. The patient is catheterized if needed, and if stitches have been taken, the stitches are cleansed by irrigation with bichloride 1 : 8,000 or with lysol one per cent., and are then powdered with boracic acid. Sterile napkins or napkins soaked in bichloride 1 : 2,000, and dried, are constantly worn. In from twenty-four to thirty-six hours after delivery, the gauze is removed from the uterus and the womb thoroughly douched with decinormal salt solution at a temperature of 105° to 110° F. To secure involution, the patient is given by the mouth gr. $\frac{1}{40}$ strychnine sulphate, and gtt. xx. fluid extract of ergot every six hours for the first forty-eight hours after delivery, beginning at such a time as the judgment of the physician may dictate. The frequency of the administration of these medicines is lessened as the condition of the patient suggests. The use of the catheter is avoided if possible, but the bladder is not allowed to become distended.

I have devoted considerable space to the prevention of post-partum hemorrhage, believing that, like septic infection, its prevention is more satisfactory than the actual treatment of the condition. In the presence, however, of post-partum hemorrhage occurring immediately after labor, the physician must quickly differentiate between a relaxed condition of the uterus and hemorrhage from a tear in the cervix, pelvic floor, or vaginal tissues. If the womb is well contracted, and the blood is bright in color, coming constantly in a small stream, its source will be found in a torn vessel in the cervix, pelvic floor, or vaginal walls. An examination should be made immediately to determine the cause of the hemorrhage, and stitches should be taken to control it. In this connection, I must call attention to lacerations in the anterior vaginal wall near the urethra as a source of hemorrhage after labor. I have seen this condition several times, and recall one instructive case as follows:

A primipara had just been delivered, by her physician, of a child by a comparatively easy application of the forceps. The placenta was removed by expression and the patient was apparently in good condition. Trickling hemorrhage, however, persisted, the cause of which was not evident to the medical attendant. The womb was well contracted, and, fearing some tear of the cervix, the vagina was immediately tamponed with gauze. The hemorrhage, however, increased, and, upon seeing the patient, I found its source to be a laceration in the anterior vaginal wall, which had opened small vessels around the urethra, extending downward from the base of the clitoris. The pressure of the vaginal tampon increased the stasis of blood and maintained the hemorrhage. The lacerations were very slight, but the vessels had been much enlarged during pregnancy, hence the bleeding. When the vaginal tampon was removed, and the parts were thoroughly irrigated with hot sterile water, the bleeding at once ceased. The patient made a good recovery.

If, however, no tear of the cervix, pelvic floor, or vaginal tissues can be found, and the womb relaxes, it should be grasped by the hand and a vaginal douche of hot sterile water, two quarts at 110° F., should be administered. Gr. $\frac{1}{30}$ sulphate of strychnine with gr. $\frac{1}{200}$ of atropine should be given hypodermatically, when, in the majority of cases, the bleeding promptly stops. Should further relaxation occur, we should immediately tampon the uterus with aseptic or iodoform gauze.

Many cases of post-partum hemorrhage following relaxation of the womb occur after the physician has left his patient and when she is in charge of the nurse. Physicians should leave with obstetric nurses written orders, stating what may be done in the event of hemorrhage before the physician arrives. It is my habit to allow a competent obstetric nurse, should hemorrhage occur before I can reach the patient, to act as follows: First, she should remove the obstetric binder, massage the uterus until it contracts, and grasp it in the manner described; second, still holding the uterus, with any aid available, she should give the patient a hot vaginal douche of two quarts of sterile water or bichloride solution 1 : 8,000 at a temperature of 110° F.; third, she should cause the patient to swallow two teaspoonfuls of fluid extract of ergot. Upon the appearance of hemorrhage, the nurse should send for the physician, but should remain grasping the uterus until the hemorrhage has entirely ceased, or until the physician arrives. Nurses should be cautioned not to fatigue the uterine muscle by useless manipulation, but, having brought it to contract by massage, to hold the womb steadily but gently in a contracted state. Post-partum hemorrhage is not very frequent when care is taken to avoid it, in my experience, and in most cases my nurses succeed in stopping the bleeding before my arrival.

Failure of the womb to remain properly contracted, persistent oozing hemorrhage in the absence of a laceration which accounts for the bleeding, must suggest to the physician that a portion of the placenta or membranes or a large clot remains within the uterus. Much stress was formerly laid upon turning out the clot to cause post-partum hemorrhage to cease. If precautions are taken to avoid hemorrhage, a large clot seldom forms. In the presence of the symptoms described, it is, however, the physician's duty to explore the interior of the womb and to be sure that it is empty and clean. This may be done with the finger, with the hot douche, or with the hot douche given through the blunt curette. Difficulty is often found in attempting to use the finger from the fact that it is hard to explore every portion of the uterine cavity in the recently emptied womb with the finger. The finger is unfortunately in many cases too short. Very often a thorough intra-uterine douche will bring away whatever is retained. In the giving of this douche, if the cervix is shut down tightly, it should be dilated gently with the finger. I prefer a glass douche tube, containing a groove along its posterior aspect, and made of especially chosen glass, which enables me to boil the tube thoroughly before using. Boiled water, decinormal salt solution, or lysol one per cent. is chosen for this purpose. I do not employ mercurial solutions within the uterine cavity unless the case is complicated by some septic condition. When the uterus is large, the functions of the finger and tube may be combined by the use of the blunt curette. The surface of the interior of the womb should be thoroughly but gently gone over while the hot fluid runs freely through the curette. If oozing continues at the conclusion of the douche, it is well to pack with gauze as described. I am quite aware that to interfere with the uterine cavity during and immediately after labor is an important procedure, but by boiling the instrument employed, by thoroughly cleansing the hands, by the plentiful use of hot dilute antiseptic fluid, and by selecting the gauze employed for the tampon carefully, I have seen none but good results follow this procedure.

If the patient is kept externally clean by antiseptic solutions, and if sterile napkins are worn, the gauze packing may safely remain without disturbance from twenty-four to thirty-six hours. It should then be removed, and the uterus thoroughly but very gently douched with decinormal salt solution at a temperature of from 105° to 110° F. This procedure requires no anæsthetic, occasions but little manipulation, and is usually well borne by the patient. For such purposes, I employ the simple glass douche tube already described, and have found it satisfactory.

In the case of highly anæmic and neurotic women, the nervous system plays an important part in causing hemorrhage. The following case of unusual hemorrhage illustrates the preceding statement:

Mrs. C——, aged forty, a married woman, was delivered of a healthy child in normal labor at the Jefferson Maternity, some two years before her recent labor. Her recovery was without complications, and she left the institution in good condition. She was recently admitted to the Maternity in labor, and in a highly exhausted condition. A macerated fœtus and its appendages were delivered; the placenta was removed by the hand, the uterus thoroughly emptied and packed with antiseptic gauze. The fœtus had been dead for some time and was considerably decomposed. The patient was given appropriate stimuli and reacted well from delivery. In view of the highly decomposed condition of the child, it was thought best to remove the gauze at the end of twenty-four hours and thoroughly irrigate the uterus. This was done, and upon removal the gauze was found to have a slightly offensive odor. Some hours afterward, the patient had a sudden and severe hemorrhage. It was controlled by removing a clot from the uterus, thoroughly irrigating it, and again tamponing with gauze. She rallied promptly from this, and apparently did well. After the removal of this packing, a further hemorrhage occurred, which was promptly controlled by the use of the blunt curette with hot antiseptic fluid. It was feared that some portion of membranes or placenta was remaining within the uterus, but none could be found. After this bleeding, the patient did well for ten days, when it was thought justifiable to take her to the obstetric clinic in the same building upon a stretcher. She did not seem especially agitated during the clinic, as she was subjected to no manipulation, and attention was simply called to her anæmic condition and the history of her bleeding. Shortly after returning to the ward, another hemorrhage occurred, much less in quantity but still distinct in character. This yielded promptly to a hot vaginal douche, and the administration of strychnine and ergot. Involution had proceeded normally; the womb was small and movable, and the source of the hemorrhage could not readily be ascertained. A fourth bleeding, slight in character, also occurred. Two blood counts were made from this patient, and are as follows: November 6th: Hæmoglobin thirty-seven per cent.; red cells, 3,450,000; white cells, 6,000. November 15th: Hæmoglobin, forty-five per cent.; red cells, 3,500,000; white cells, 2,800.

An examination of the pelvic organs at the time of writing gives the following results: The pelvic floor is in good condition. It has been slightly lacerated in previous labors, but the lacerations have been closed and have healed. The womb is slightly retroverted, movable, slightly larger than normal, but involution has proceeded quite as well as in the majority of multiparæ. There is a whitish secretion of mucus in the vagina. Upon examining the cervix with a speculum, the mucous membrane is healthy in color. There is no extensive laceration, and no sign of ulceration is present. The external genital organs show no positive evidence of specific infection.

The patient's general condition is greatly improved. Obstinate hemicrania, from which she suffered at first, has largely disappeared, and she is convalescent at present. Her treatment in addition to the local treatment described has been as follows: She has taken three times daily, before eating, a mixture of Fowler's solution, gentian, and simple elixir, the dose of Fowler's solution varying from one and a half to three drops at each administration. After eating, tincture of chloride of iron has been administered in increasing doses until she has taken thirty drops three times daily. Attention has been paid to the condition of the intestinal tract, and purgatives of various sorts with saline laxatives have been given as needed.

The question of syphilitic infection enters naturally into consideration in this case. The statement was made by some one knowing the patient's circumstances before admission, that her husband had become recently syphilitic and had infected her. At the time of the patient's labor, no lesion was discovered in the genital canal indicating specific disease. The presence of a macerated fœtus points strongly to syphilitic infection of the ovum, with the resulting changes in the endometrium and decidua commonly seen in these cases. There can be no reasonable doubt that this condition of the maternal tissues had something to do with the patient's repeated hemorrhages. That she herself is syphilitic in the usual sense of the word and in the acute stage cannot be proven.

I may summarize this case as follows: A multipara became, during her pregnancy, anæmic and reduced in strength through hard work and the presence of a macerated fœtus within the womb. We must suppose that the endometrium and decidua became extensively altered, very probably through syphilis of the ovum, and that its blood-vessels were in an unusually friable condition. The expulsion of the macerated fœtus was followed by relaxation of the womb and hemorrhage at varying intervals in spite of the persistent administration of tonics and stimulants, strychnine and ergot being given in large doses during the first ten days of the patient's puerperal period. During this time, she had four hemorrhages without apparent cause. Each was immediately controlled by methods described. Her convalescence has covered a period of between two and three months, her gain in hæmoglobin being practically one per cent. daily during the time of her most rapid recovery. She had a rise of temperature after delivery, indicating sapræmic absorption, but this rapidly declined to normal.

Medicine in Whiskey Bottles.—It will be remembered, says the *British Pharmaceutical Journal*, with what indignation the parish beadle in "Oliver Twist" related the rejection of some stuff in a blacking bottle intended for a sick pauper woman. "Nous avons changé tout cela," but there still remain a few features of the ancient system which have lately been responsible for a poisoning fatality. An old lady in Ireland had been for some time attended by the dispensary medical officer for an affection of the knee-joint. Some time ago she got a lotion which contained poison, and took the lotion by mistake for whiskey. She exhibited all the symptoms of belladonna poisoning.

THE QUESTION OF LEGAL CONTROL OF PROSTITUTION IN AMERICA.[1]

By S. LUSTGARTEN, M.D.,

NEW YORK.

DELEGATE FROM THE UNITED STATES GOVERNMENT.

In discussing the question of legal control of prostitution in America (the United States) we approach a subject that is almost entirely new. In but one instance, and but for a short time, have there been laws enacted by a State for the regulation of prostitution, with a view to prevent disease. This solitary experiment occurred in St. Louis, in 1872. A law, drafted upon the lines of that in operation in Paris, was enacted by the Missouri legislature, the object of which was to regulate and bring under control prostitution in the city of St. Louis. The provisions of this law—I quote freely from the appendix of the new edition of Sanger's book on prostitution—were substantially as follows: All prostitutes plying their avocation were registered. These were divided in three classes—the inmates of houses, the occupants of rooms outside of such houses, and those known as "kept women," or mistresses. There was no distinction whatever between these classes. In the eyes of the law, the "kept woman" was quite as much a prostitute, and subject to the provisions of the law, as her less fortunate sister in the common disorderly house. No registered woman was permitted to change her abode without first giving notice to the authorities, so that her whereabouts was constantly known. Many of the more vicious and corrupt practices of the business were absolutely prohibited, and practically suppressed. Soliciting, either on the street or from windows or doors of houses of prostitution, was severely punished, a second offence generally resulting in a deportation of the offender from the city as a vagrant. No carriage or public conveyance was permitted to stop or stand in front of a house. No red lamp of sin was tolerated; in short, no light of a color calculated to attract attention was allowed in hallway or parlor. The front doors of all houses were kept unlocked, thus admitting, at all hours, not only the patrons but the police as well. In fact, every barrier between the authorities and the vicious class was, as far as possible, removed.

The city was divided into three districts, both in respect to sanitary and police regulations. A physician of recognized standing, called "social-evil examiner," was placed in charge of each of these districts, whose duty it was to compel weekly medical inspection of each and all the registered unfortunates. A nominal fee was collected weekly from the inmates of houses and rooms, and a larger fee from the proprietors of houses. The money thus collected went indirectly back, to a great extent, to those contributing it, as it was largely devoted to the maintenance of a hospital open at all times to the members of this unfortunate class.

Apparently well-informed writers, as well as many of the leading physicians of the city, could discern salutary effects after the law had been in operation but a short time. Venereal diseases decreased in a marked way, and the evil itself was lessened, many of the members of a bad class preferring to leave the community sooner than subject themselves to the requirements of the new law. This latter movement, this shifting of prostitution, can be ranked only among the salutary effects if viewed from the selfish point of a comparatively limited area, a city, or even a State. The sanitation of the United States was surely not improved through it. The *Missouri Medical Record* (May 15, 1874), in an article printed a few weeks after the repeal of the law, stated that the system had operated most beneficially in the interests of the community, as well as the welfare of the prostitutes; that many of the inmates of the hospital, influenced by the ministrations of good men and noble women, have been seeking a "purer, a better" way, and have become so fully aware of the physical advantages arising out of the law that not a few of them voluntarily subjected themselves to the inspection, at their own expense, after the abrogation of the law. It is to be regretted that the absence of statistics detracts so much from the scientific value of these observations.

For about a year only this law remained on the statute books of the State. The incidents—I quote the language of a St. Louis law journal (*Morning Advertiser*, January 12, 1895)—attending its repeal were dramatic. Throughout the State there was a moral uprising against what was regarded as the licensing of vice, and the lobbies of both branches of the legislature were taken complete possession of by the clergy of the various denominations, and earnest co-workers of the other sex. A petition praying for the repeal of the obnoxious law, signed by more than one hundred thousand good people, was presented. The document was cumbersome. A wheel-barrow, decorated with white ribbons and accompanied by a group of innocent young girls, attired in spotless white gowns, was brought into service, on which the gigantic and emphatic protest against the licensing of vice was wheeled up to the clerk's desk to be read. There were, of course, counter-petitions from the cities, and conspicuous among the signers of these latter were members of the medical profession. But the overwhelming sentiment was against the law, the members, without exception, representing a country constituency voting against it.

Thus ended the short-lived and solitary experiment, and we may well ask why, during a period of almost thirty years, not one of the many States which constitute the Union has again approached this subject, and why, to-day, the enactment of a social-evil law in the United States is as remote as ever.

Assuming State intervention to be desirable, there are difficulties opposing its introduction, and these are public opinion, probable lack of constitutional power, and also the difficulty of uniform regulations.

As to the law, it must be remembered that every State of the Union that is known as the United States of America is a separate and distinct sovereignty. Each State has its respective constitution. The United States, a federal government, has its constitution. Excepting so far as each State has surrendered its sovereignty, each is as distinct the one from the other as Greece from Italy. The federal constitution embodies power which each State altogether has surrendered. Back of the constitution of the United States lie the sovereign people, who can change that constitution. This, however, is exercised exceptionally.

Every law, then, that is enacted by any or all of the forty-five separate sovereignties may have to stand the test of each State constitution, and ultimately that of the United States, and such would be the case when a law is passed that in any way infringes upon individual liberty. The law of the United States, generally speaking, is based upon the law of England. It breathes forth that spirit of individual rights, personal liberty and freedom, that reverence for the sanctity of the private home and life within it, that has ever been the pride of Englishmen and Americans. The constitution of the United States (in the Fourteenth Amendment) provides that "no State shall deprive any person of life, liberty, or property without due process of law, nor deny to any person within its jurisdiction the equal protection of the law." That amendment limits the powers of the individual States. Any law regulating prostitution must be so formed as not to violate that amendment. Most of the State constitutions contain similar provisions, and all laws must be subject to them, and under scrutiny of the highest State courts. It may, therefore, very reasonably be a question whether any effective laws could be passed that would not violate either the State or federal constitutions or all of them.

---

[1] A contribution to the transactions of the International Conference for the Prevention of Syphilis and Venereal Diseases, held in Brussels, September, 1899.

There is a further difficulty. The federal government has only the powers enumerated in the federal constitution. In that constitution there is no provision, I am advised, that would permit of a federal regulation of prostitution. Accordingly there is no power to compel an unwilling State to pass such regulations, and it can be readily seen that, unless a vast majority of the forty-five States adopted the same, or similar, regulations, no beneficial consequences could ensue. This is no imaginary or purely academical difficulty. In matters wherein public sentiment is in accord, uniform laws throughout the States are wanting. I am advised that in this great commercial community the laws pertaining to commercial paper differ in different States, leading to much embarrassment. Such is likewise the case in regard to many other laws, commercial and criminal. Here, then, is a practical difficulty, that of uniform legislation; and this leads us to the next consideration—that of public opinion. Public opinion is largely public sentiment. Public opinion, of necessity, must be in accord throughout the Union in order that the individual State legislatures should enact uniform laws on this subject. It is not necessary to analyze public opinion in America. Let it suffice to say that in no country of such magnitude does public opinion exert so much direct influence on those who are placed in authority, both to make and administer the laws. This condition of affairs will assist us in enacting regulations, if public opinion be in accord, but all the indications are that it is in opposition to the matter under discussion.

First, there is the sentiment that prostitution should not, upon moral grounds, receive recognition by the State. That view is shared by very many people. It is that sentiment that permits street-walking in London. Here it is that more or less strong laws are enacted punishing adultery, fornication, street-walking, and the various States have a variety of penal laws against such crimes. Separation by a husband or wife from the other is allowed by the courts because of disease communicated. Impotence is a ground for annulment of the marriage. On the whole, however, the sentiment exists that abhors State interference, on moral grounds. That disease is communicated is said to be fit punishment for sexual indulgence.

Another sentiment is based upon personal liberty. Each citizen is conscious of his position as one of the sovereign people, and those in power are his servants, and there at his will. The administration of such laws as would have to be enacted to prove effectual would be a practical impossibility. The natural privacy that accompanies indulgence in sexual intercourse is invaded. As illustrative of the above sentiments, as well as the further one that such regulations debase the individual, is the short and calamitous life of the laws enacted in 1870 in Missouri. Amid wild enthusiasm, where young girls in pure white, bedecked with flowers, paraded, symbolical of purity and chastity, was the law repealed.

Public sentiment looks, however, to therapeutics as the solution. The Americans are progressive and ready to learn. Could it be demonstrated beyond a doubt, by the experience of other countries, that the result of such regulations is, as a matter of fact, highly beneficial, and that mankind is not debased thereby, public sentiment would doubtless change. That time, however, has not yet come, and the United States will, I feel, still stand by and watch the experiments made abroad before adopting measures foreign to the spirit of its people and its laws.

Copaiba in Diabetes.—Dr. Bettmann (*Berliner klinische Wochenschr.*, S. 479, 1899) has observed that the administration to diabetic patients of copaiba, even in small doses, causes an increase in the excretion of sugar; the urine contains double, sometimes treble the quantity normally excreted. Turpentine and essential oils have a similar action.

Observations on the Relation of the Uterus to the Thyroid Gland. — Dr. Charles R. Dickson (*Charlotte Medical Journal*, October, 1899) summarizes as follows: In treating diseases of the thyroid gland in women it is wise to inquire into the condition and habits of the uterus, and to devote some attention to it as well as, if not instead of, the thyroid. Very active measures should be omitted before puberty, during menstruation and pregnancy, while the climacteric is a time for especial suspicion.

The Influenza Heart.—After mentioning the various forms in which influenza manifests itself, Dr. Robert Saundby (*Birmingham Medical Review*, November, 1899) says that among the more frequent sequelæ we must reckon affections of the heart. These are more frequent than is suggested by the number in which the relationship can be strictly proved, for the initial attack of influenza which has set up the cardiac disturbance may pass unrecognized. The cardiac troubles of influenza may be either functional or organic. The functional troubles are alterations in the cardiac rhythm, tachycardia less often than bradycardia. These conditions have not been always obvious. The alteration of the pulse in many cases has been variable, or has been absent, except at certain times or under special conditions. The patients complain of weakness or faintness on exertion, or may express themselves as only generally weak and inapt for their ordinary business. On examination the pulse may be too quick, feeble, and small; more often it is slow, irregular, and intermittent, but is subject to great variations. The irregularity may be noticeable only in the early morning, and disappear later, or be brought on by exertion, fatigue, digestion, the use of alcohol, tobacco, tea, etc. He has noticed that these patients referred their symptoms rarely to their hearts, so that without examination such cases may be overlooked. In the other group, where there is definite organic disease, the heart is dilated, and there are all the indications of insufficiency of the left ventricle, breathlessness, œdema of the feet, etc. There is always danger of the functional cases becoming organic—that is, of the neuro-motor mechanical derangement resulting in muscular degeneration. The mischief probably begins in the cardiac ganglia or nerve, but when the intoxication is sufficiently intense and persistent the myocardium sooner or later becomes implicated. Dilatation is due to a subacute myocarditis. With proper care compensatory hypertrophy takes place. There is a marked tendency to recurrence of the cardiac trouble whenever a renewal of grippe infection occurs. The cardiac enlargement is, as a rule, easily made out, and dulness may extend to beyond the anterior axillary line. There may be no murmur; occasionally there is a systolic murmur at the apex transmitted to the axilla associated with an accentuated pulmonary second sound. The urine is free from albumin. Gastric complications are very common.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, January 13, 1900.

THE HOUSING OF THE POOR.

THIS is a difficulty which becomes more embarrassing and increases in importance year by year. Indeed it would be no exaggeration to say that it is one of the paramount questions of the hour. Legislators and philanthropists are at their wits' end to devise a satisfactory scheme to house the working-classes, and to dispose of the surplus population. The rush of people from rural districts in commercial countries to the large towns shows no tendency to abate, and the consequence is that in unwieldy, overgrown cities like New York and London, the working and pauper classes are for the most part compelled to live under conditions which are not only in a high degree prejudicial to their own health, but also constitute a standing menace to the physical well-being of the entire community. The point that it is to the interests of the public as a whole for the poorer classes to be housed in a sanitary manner, and that their environment generally should conform to the requirements of modern hygiene, is one that does not seem as yet to have been thoroughly grasped and its true significance appreciated by municipalities. In order that a nation should prosper it is necessary that its individual members should be sound physically and mentally. To gain this end, disease must be eradicated as far as is possible, and to curtail the spread of disease the most effective measures must be taken to insure to every one the means of living in healthy surroundings. The obstacles in the way of successfully accomplishing this object are undeniably hard to overcome, but they are not insurmountable.

The problem of housing the poor in London has so thrust itself to the front that thoughtful men have decided that it must be promptly faced, and methods of various kinds have been suggested as a solution. It is true that in the British metropolis the municipal authorities and county council have taken up the matter vigorously, and have effected many improvements Acres of unsavory rookeries have been cleared away, and on the site fine, well-built sanitary dwellings have been erected. Unfortunately this remedy is but partial. The people ousted from the old houses are not able to afford the rents demanded in the new buildings, and are thus compelled to settle in some other poverty-stricken and overcrowded district. A suggestion has recently been advanced that houses for workmen should be built outside the boundaries of London, and which might be reached by trains run at specially cheap rates. If such a plan could be successfully carried out, undoubtedly a great part of the working population could be housed more healthily and at a less cost than in London itself. However, at present red tape blocks the way to this scheme, and until existing laws are repealed the poor must stay within the limits of London.

The situation of the working-classes of New York, so far as house accommodation is concerned, is said to be—by those who have had experience of these matters—much worse than in London. It is computed that the population in the tenement district of the former city is twice as dense as in the most crowded parts of the latter. At the time when there was no restriction on immigration, the scum of the nations came to New York, herding like cattle in the poorer portions of the town. The efforts of the organized charities in the direction of improving the lot of the poor have been attended with much success, but little has been done toward the provision of clean and healthy homes.

The report of the tenement-house committee of the Charity Organization Society has just been published. This committee was formed in 1898 with the object of considering the necessity and advisability of taking action looking toward the improvement of the condition of the tenement houses in the city. Two bills to amend some objectionable points in the charter were introduced into the State legislature, but were not manipulated through that body. The committee also framed a series of proposed ordinances, which, while in no respect conflicting with any sections of the present charter, would at the same time have greatly bettered the state of the tenement dwellings. The Building Code Commission did not see their way to, or were not desirous of, adopting any of these suggestions, and thus so far the labors of the tenement committee have been of no avail. However, although discouraged, its members have no intention of giving up the struggle, and as the sentiment of the intelligent part of the community would seem to be with them, there is reason to hope that in the end their philanthropic efforts will have a satisfactory issue. It is a decided slur on the rich and influential inhabitants of New York that the poor should be forced to live under conditions so insanitary.

THE SANITARY ASPECT OF THE WAR IN SOUTH AFRICA.

DESPITE the healthfulness of the South African climate it cannot be reasonably anticipated, with so large a body of men living under the conditions to which soldiers in the field are compelled to submit, that disease will not claim its share of victims. The exigencies of war do not permit an approach to perfection in the sanitary arrangements of camps, but unless every effort is made to place these upon as satisfactory a basis as possible, disastrous results will inevitably follow.

The truth of this statement is so fully recognized that it would be idle to multiply instances in proof. The state of some of our camps during the Spanish war is a sufficiently striking object-lesson. The surgeon-general of the United States army, referring to this feature, speaks as follows: "The sanitary condition of the permanent camps before the war was excellent, but the new camps formed on the outbreak of the war, and filled with undisciplined volunteers, speedily became hot-beds of disease, especially of typhoid fever, from which they suffered severely in July and August."

The British troops in Africa are disciplined, and, moreover, the greater portion of them have had experience of tropical climates, but with all these facts in their favor unceasing vigilance will be needed on the part of their medical officers to ward off and hold in check the maladies common to South Africa at this season of the year. Enteric fever is very prevalent, particularly in the high lands, and February, March, and April are the months in which it is most rampant. Dysentery and diarrhœa are said to be epidemic in the Transvaal before the rainy season. Parasitic diseases due to eating uncooked vegetables and some forms of uncooked meat are of frequent occurrence. In addition to these complaints indigenous to South Africa an outbreak of smallpox is reported at the Cape, while at Delagoa Bay and vicinity are many cases of bubonic plague.

The duty of supervising the sanitary arrangements of the camps will, it appears, devolve upon the army surgeons. The London *Lancet* says: "No special sanitary officer is appointed to the forces, nor is any such appointment provided for in war establishments, but the medical arrangements entail ceaseless vigilance over his particular charge upon every medical officer, who is thus constituted an ex-officio sanitary officer." It is therefore clear that the already confessedly insufficient British army medical corps will have a most onerous task to undertake successfully the double duty of attending to the sick and wounded and of insuring the proper sanitation of the camps. Indeed, the question as to whether its members will be equal to the strain has been mooted in some of the British journals. The London *Practitioner* makes the following suggestions: "For the protection of the forces in South Africa against the dangers that may arise from official ignorance or apathy the government would be well advised if they appointed one or two consulting physicians to the forces, who should hold the same relation to the royal army medical corps as the consulting surgeons who have been sent out. These sanitary commissioners, in addition to their special knowledge, would be in a disciplinary sense independent of the military authorities, and could therefore offer advice not merely 'when it is wanted,' as Lord Wolseley graciously allows, but when it is not wanted, and they could insist at least on its receiving serious attention. The services in such a capacity of a man of independent position, combining medical knowledge with official experience in sanitary administration, would be invaluable."

It is probable, and in fact now seems certain, that the war in South Africa will drag on for many months, during which time the British soldiers must live in camps. In order to keep the camps in a healthy condition strict overlooking by men experienced in sanitary matters will be necessary. It would seem that by following the advice of the *Practitioner* a long step toward attaining the desired object would be made.

INTRA-ABDOMINAL BILOCULAR HYDROCELE.

Bilocular or hour-glass hydrocele is not a common affection, although Monod and Terrillon, in their excellent treatise on "Les Maladies du Testicule," treat of it at considerable length. The affection has also been studied by Dupuytren, who described it under the name of "hydrocèle en bissac," Chelius, Berger, Malgaigne, and Duplay, and more recently by Kocher, Trendelenburg, Humphry, and Bazy. The unique characteristic of the tumor is that it consists of two sacs, one abdominal, the other sciatal, which communicate more or less freely by means of a narrowed part lying in the inguinal canal. It sometimes attains colossal dimensions. In a case reported by Rochard, the abdominal portion of the tumor extended upward to the umbilicus, passing the median line, and losing itself behind and below in the iliac fossa. On puncturing it, nearly three litres of fluid were withdrawn. The tumor was still larger in one of Bazy's patients, passing considerably above the umbilicus, and beyond the median line.

In the *Wiener klinische Wochenschrift*, No. 46, 1899. Dr. Winiwarter reports a like case in a man, thirty-one years of age, who gave the history of having had a hydrocele the size of an egg in the right scrotum since his youth. For two years the swelling had increased in size, reaching the volume of about two fists, and it also extended up into the abdomen. About a year before, the hydrocele had been punctured, giving exit to seven litres of clear, straw-colored fluid. Five weeks later it was again punctured, yielding about the same quantity of fluid. After eleven weeks a third puncture was made. When the patient was received into the hospital, he was much emaciated, anæmic, pale, having an extremely rapid pulse, and a temperature a little above normal. The feet were somewhat swollen. The urine was free from albumin; the lungs and heart were sound. Within the abdomen was a large swelling, clearly cystic in character, which extended from the right scrotum to the ribs. The circumference of the abdomen at the umbilicus measured 93 cm. The scrotal tumor could not be pressed toward the abdomen, though a percussion wave could be transmitted from one sac to the other. After removal o the sac, its length was found to be 40 cm., and its greatest breadth 23 cm. A bilocular hydrocele is generally spherical in shape, though in Kocher's case it was elongated like a thick sausage. Whatever may be its shape or size, the intra-abdominal part is always a pouch closed at the top, and absolutely independent of the peritoneal cavity.

As to the exact relations between the hydrocele and peritoneum, there is still much to be learned. Bilocular hydrocele may be bilateral (Kocher, Fano), but it generally occurs on one side only. The diagnosis is as a rule easy. A differential point of great value is that reduction is never absolute as in congenital hydrocele. In children, the abdominal sac may be so deeply placed that exploration by external palpation alone is impossible, and examination under narcosis as recommended by Kocher, by means of abdominal palpation and rectal touch, will alone clear up the nature of the case.

Authors disagree concerning the pathogeny of this affection, particularly as to the mode of formation of the abdominal part. Some think it is developed by the simple expansion of a common hydrocele through an accumulation of fluid; others, that the upper pouch exists from the first. The occurrence of bilocular hydrocele depends on faulty development of the coverings of the testicle. The prognosis depends especially on the size of the tumor and its relations to the peritoneum. The treatment is the same as that of simple hydrocele, namely puncture, puncture followed by the injection of iodine or other irritant, simple incision, or excision and removal. The latter is to be recommended when simpler methods have proved unsuccessful. This was employed in Winiwarter's case with complete success.

News of the Week.

Suing for Professional Services. — Dr. Branth of this city recently sued a wealthy client for $600 as a well-earned fee, but received only $200, the defendant repudiating all promises as to proper remuneration. The old story. The ordinary juryman believes in cheap medical services.

New Hospitals.—An additional orthodox Jewish hospital having been projected in the southern section of Philadelphia, to be known as the Beth Israel Hospital, a dissenting faction has secured a charter for another hospital, which is to be conducted as a nonsectarian institution, and is to be known as the Mount Sinai Hospital.

The Medical Inspection of Schools.—From among more than three hundred physicians recommended by the deans of medical colleges, the authorities of the hospitals, sectional school boards, and citizens, the Philadelphia board of education has been able to assign physicians to about two hundred and ten schools to make daily medical inspection of pupils presenting symptoms of illness. The work of examination in the schools is expected to begin on January 8th. Each physician will be expected to visit the school to which he is assigned between 9:30 and 10 each morning, and he will examine such children as are brought to him by the principal. If any pupil has, or is threatened with, any disease that is infectious or contagious the child will be sent home, with instructions to the family to consult a physician, and it will not be permitted to return to school without a proper certificate from a medical inspector of the bureau of health that it is safe to do so. Should the pupil require medical treatment for any other complaint notice will be sent to the family with the child on its return home. For the present the work is to be done without remuneration, but it is hoped that fair compensation will be paid for the service when the time for making appropriations comes.

The Progress of the Christian Science Movement.—Mrs. Mary Baker Eddy, the head of the Christian Science cult, has, it is announced, given her son a check for $10,000 and a house worth $15,000 as a Christmas present.

The Schuylkill County (Pa.) Medical Society elected the following officers on January 2d: *President*, Dr. W. C. J. Smith; *Vice-President*, Dr. A. L. Gillars; *Treasurer*, Dr. D. Taggart; *Secretary*, Dr. G. W. Farquhar; *Censor*, Dr. A. P. Carr.

The Study of Cancer at Harvard University.—By the will of Mrs. Caroline Brewer Croft, who died about two years ago, a sum amounting to nearly $100,000 has been placed in the hands of the corporation of Harvard University to be used in the investigation of the nature and therapy of cancer. Mrs. Croft was a native of Boston, but had lived for many years in England. Her early charitable efforts impressed upon her the horror of malignant disease, and for many years before her death she gave large sums annually for the relief of the poor who suffered from cancer.

College of Physicians of Philadelphia.—At a stated meeting held January 3, 1900, Dr. F. Savary Pearce read a paper entitled "The Gastro-Intestinal Tract in Nervous Diseases," in which he dwelt upon the necessity of eliminative treatment directed to the digestive tract for the relief of varied nervous manifestations, and reciting numerous illustrative cases. Dr. Frances R. Packard read a paper entitled "A Brief History of the Medical Societies which Existed in this Country Prior to the Founding of the College of Physicians of Philadelphia, in 1787." It was shown that only three societies, the New Jersey State Medical Society, the Massachusetts State Medical Society, and the New Haven Medical Society, had an earlier and continued existence than the College of Physicians. Dr. Packard read also a paper entitled "Some Old Certificates of Proficiency in Medicine." Dr. John G. Clark delivered an address, with lantern demonstrations, upon "The Vascularization of the Ovary and its Bearing upon the Differentiation of Sex, Origin, Development, and Degeneration of the Graafian Follicle, Inauguration of Ovulation, Organization of the Corpus Luteum, and the Final Cessation of Ovulation (Menopause)." Dr. W. W. Keen was elected president and Dr. Horatio C. Wood vice-president for the ensuing year.

Jefferson Medical College.—At a meeting of the Philadelphia Chapter of the Alumni Association of Jefferson Medical College on January 2d, Dr. Lawrence F. Flick discussed the prevention of tuberculosis. He said that to this end the people must be educated as to the contagious nature of the disease;

State hospitals for the treatment of cases in the incipient stages must be erected, with registration of cases and the application of the general principles of isolation and disinfection. Dr. J. C. Wilson expressed hope for an anti-tuberculous serum, and emphasized the importance of improving the nutrition by means of abundant alimentation, an open-air life, long hours of sleep, and the discipline of a sanatorium.

The Altoona (Pa.) Academy of Medicine and Surgery elected the following officers on January 2d: *President*, Dr. S. L. McCarthy; *Secretary*, Dr. E. S. Miller; *Treasurer*, Dr. J. U. Blose; *Trustee*, W. M. Findley.

Munificent Bequests.—By the will of Captain Jacob Jay Vandergrift, who died recently at Pittsburg, Pa., the following bequests are made: The Homœopathic Hospital of Pittsburg, $5,000; the Allegheny General Hospital, $2,500; the West Penn Hospital, $2,500; the Pittsburg Free Dispensary, $2,500; the Home for Incurables, $1,000.

Plea for Pure Water.—Dr. Benjamin Lee, secretary of the Pennsylvania State board of health, Dr. A. C. Abbott, bacteriologist to the Philadelphia bureau of health, and Dr. George Woodward, a member of the common council of Philadelphia, appeared before the town council of Norristown recently for the purpose of encouraging the erection of a sewage-disposal plant for the borough. Their efforts were, however, met with the response that the city should first cleanse the waters of the stream at its own doors before asking the boroughs to take action.

Episcopal Hospital, Philadelphia.—At the annual meeting of the board of managers on January 4th attention was called to the large and increasing number of dispensary patients. The necessity for a new dispensary was shown, and a recommendation was made for the erection in the near future of the "Aspinwall Ward" for poor, white, female orphan children who have been ill and are convalescent. The fund for this purpose was bequeathed to the hospital a few years ago by Anna Ross Aspinwall, of Pittsburg, and has a cash value of $200,000. During the past year 2,737 patients were admitted to the hospital, and 34,100 new patients were treated in the dispensaries, with 72,595 return visits.

Philadelphia County Medical Society.—At a stated meeting held December 27th, Dr. M. A. Bunce read a paper entitled, "Vasomotor Ataxia," and he presented illustrative cases. The designation is applied generically to conditions attended with abnormal vascular contraction or dilatation, in association with local changes in color, from white to pink and red or blue, and allied phenomena, in consequence of undue susceptibility to various stimuli, extrinsic or intrinsic. Dr. G. Betton Massey read a paper entitled "Some Cases in Conservative Gynæcology," in which he made a plea for the employment of electricity in a wider range of cases than are now treated by this means. Dr. W. Joseph Hearn read a paper entitled "Appendicitis; the Proper Time for Operation and its Mortality," citing statistics showing a death rate of from four to six per cent. Dr. S. Solis-Cohen presented a communication entitled "The Use of Palladium Chloride Internally in the Treatment of Tuberculosis," detailing the results of an experience extending over a period of three years. The preparation employed consisted of a solution of 5 gm. to the ounce made with the aid of hydrochloric acid, and of which from 5 to 10 drops were administered thrice daily. Fever seemed to subside, the cough to diminish, and weight to increase. The drug is thought to be in no wise a specific, but simply an additional aid in the treatment of a disease whose most important therapeutic factors are hygiene and nutrition.

Dr. Thomas Lauder Brunton, physician to St. Bartholomew's Hospital, London, and formerly editor of *The Practitioner*, has been knighted by the queen.

Typhoid Fever is raging in Kiao-Chau, Germany's new Chinese possession, twenty-nine members of the garrison having died of that disease during November. The governor, Herr Jaeschke, has suffered among others.

Medical Matters in the Boer War.—The British government has appointed from civil life four additional consulting surgeons for the army in South Africa. These are Sir William Stokes and Mr. Kendal Franks, of Dublin, and Messrs. W. Watson Cheyne and G. L. Cheatle, of London. Mr. Kendal Franks was for some time before the war resident in Johannesburg.—At a meeting held recently in London a committee of women was formed to equip an hospital base for the yeomanry who have been called out to reinforce the troops in Natal. The membership of the committee comprises most of the women of the British nobility.—Typhoid fever and dysentery are reported to be spreading in Ladysmith and other beleaguered towns.—The British troops are harassed greatly by the heat, to which they are unaccustomed, and the wounded especially suffer from it. In a letter to the *British Medical Journal*, Mr. Makins, one of the civilian consulting surgeons with the troops at Orange River, writes: "During an eight days' stay some six hundred wounded men have passed through the hands of the royal army medical corps here. In one night alone three hundred patients arrived from the fight at Modder River. Yesterday the thermometer registered 115° F. in some of the tents. The fact that the journey from here to the base hospital at Wynberg takes twenty-eight hours emphasizes the difficulties due to the immense length of the line of communication." He adds his testimony to that of the surgeons in our recent war concerning the benignity of the Mauser and the Lee-Metford bullets. A wounded Boer referred to the latter as a "gentlemanly bullet," "and this remark," he said, "is equally applicable to the Mauser. The wounds made by them are small, clean, and little disposed to suppurate."

The Chair of Psychology at Columbia.—Mr. John D. Rockefeller has given $100,000 to endow the chair of psychology at Columbia University. In their resolution of thanks to the donor, the trustees of the university state that Dr. James McKean Cattell, who holds the chair at Columbia, was the first professor of this science to be appointed in any university, American or foreign. There are now five special instructors in this department at Columbia, and the new donation will make it possible for them to carry on their work to much greater advantage.

Measles is epidemic in Newburg, N. Y., among all classes of the community. On January 5th there were over three hundred cases of the disease in the city, and from fifteen to twenty new cases are reported daily. Adults as well as children have been attacked.

The New York Academy of Medicine has paid the last item of its indebtedness, amounting to $2,000, and is now wholly out of debt for the first time since the completion of its building. The latter cost nearly a quarter of a million dollars.

American Delegates to the International Congress.—The President has designated the following officials to represent the United States government at the International Medical Congress in Paris August 2d, and at the Congress of Hygiene and Demography, which assembles at the same place August 10th: For the army, Surgeon-General Sternberg and Surgeon Lagarde; for the navy, Surgeon-General Van Reypen; for the Marine-Hospital service, Surgeon-General Wyman and Passed Assistant Surgeon Rosenau.

Professor Schenk Removed.—Dr. S. L. Schenk, professor of embryology and histology, and director of the Embryological Institute at the University of Vienna, has been retired on a pension. This action is in answer to a petition from the medical faculty of the university alleging the publication in the lay press of scientific theories constituting a form of advertisement. Dr. Schenk, it will be remembered, is the man who, not long ago, published a saccharine theory of sex production and made a little noise in the newspaper world. He had been director of the Embryological Institute for twenty-six years.

A Poison Bottle.—Senator Wilcox, of Auburn, purposes introducing into the New York legislature a bill providing that any bottle containing poison shall be of such peculiar shape that it can be readily distinguished in the dark by the touch. A similar bill was introduced at each of the two preceding terms of the legislature, but was defeated on the ground of discrimination in favor of some particular manufacturer who might secure a patent upon his design. To avoid this a provision will be incorporated in the bill that the style of bottle shall be determined by a committee of the State Medical Society, acting in conjunction with the State board of health.

Shorter Hours for Drug Clerks.—Dr. Nelson H. Henry, of this city, will introduce in the State Assembly a bill providing that drug clerks in cities of the first class shall not have more than seventy hours of work a week. It permits six hours' overtime during any week for the purpose of making a shorter succeeding week, but the aggregate number of working-hours in any two weeks shall not exceed one hundred and forty. No proprietor of any drug store shall require or permit any clerk to sleep in any room or apartment in or connected with the store, which does not comply with the sanitary regulations of the local board of health. The bill has been indorsed by many of the pharmaceutical associations in New York City. The Druggists' League for Shorter Hours has prepared another bill for introduction this year. It differs from Dr. Henry's in that it provides for one hundred and thirty-two hours of labor in two weeks instead of one hundred and forty, and empowers the city board of health to frame regulations and secure the enforcement of the law.

A Busy New Year's Day.—The ambulance department of Bellevue Hospital broke the record on January 1st of this year. All told fifty-six calls were answered. The majority of the patients were treated in the alcoholic ward.

The New York Neurological Society.—At the annual meeting of this society, held January 2d, the following officers were elected: *President*, Frederick Peterson; *First Vice-President*, Joseph Collins; *Second Vice-President*, L. Stieglitz; *Recording Secretary*, Pearce Bailey; *Corresponding Secretary*, Lewis A. Conner; *Treasurer*, Graeme M. Hammond; *Councillors*, C. L. Dana, M. A. Starr, B. Sachs, E. D. Fisher, and J. Arthur Booth.

The Rhyme of the Bramble Bush in Real Life.—A street car struck Giuseppe Marate, a sailor, in Philadelphia, Christmas Day, knocked him down, and dislocated his shoulder. He was put into a wagon and hurried off toward the Pennsylvania Hospital. The wagon jumped over a rut in the pavement and the jar reset the shoulder. When he got to the hospital the surgeons found the shoulder all right, bandaged it, and sent him back to his vessel.

An Electric Ambulance.—St. Vincent's Hospital has now a horseless ambulance. It is operated by an electric motor supplied with power from a storage battery. In many respects it is similar to the present city ambulances in use, but it is equipped with sliding glass doors for use in stormy weather. The operator will sit on a seat at the front similar to the seats of the old ambulances, and will be able to get up a speed of ten miles an hour. The vehicle is a gift of Mr. Edward Kelly.

The Plague is extending in Brazil, and has now been declared epidemic in the city of São Paulo.—In Honolulu, up to the first of the year, there had been seventeen cases officially recognized as plague. There had been a number of deaths from what was probably plague, but had not been declared to be such. The board of health has adopted measures which can be called energetic at least. The infected district has been surrounded by a military cordon, and several buildings in which the plague cases occurred have been burned. The invasion of the Hawaiian Islands has caused alarm on the Pacific coast, and special precautions will be taken to prevent the introduction of the disease into any of the ports of this country and British Columbia. A quarantine has been declared against vessels from Honolulu, and all vessels coming from any infected or suspected place will be required hereafter to use funnel guards over their hawsers to prevent the rats from going ashore.—The plague has broken out among the Chinese laborers on the Manchuria railroad, and it has been decided, at the instance of the Russian minister of finance, to dispatch a sanitary corps of doctors and Sisters of Mercy from St. Petersburg to Manchuria to combat the disease.—On January 8th it was reported that there had been six cases of plague with four deaths at Manila. All the cases thus far have been among the natives. The disease was probably imported from Hong Kong. The medical officers at all times have been on the watch to prevent this, but owing to the short distance from Hong Kong to Manila, and the large amount of traffic carried on in a small way by native junks and dhows, the ultimate introduction of the disease into Manila was inevitable.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending January 6, 1900. December 30th.—Passed Assistant Surgeon A. W. Dunbar ordered to duty on the *Monongahela*, immediately. January 2d.—Passed Assistant Surgeon R. K. Smith detached from the naval hospital, Mare Island, Cal., on reporting of relief, and ordered to duty on the *Pensacola;* Assistant Surgeon J. H. Payne detached from the *Indiana* and ordered to duty at the naval hospital, Mare Island, Cal. January 3d.—Medical Director A. F. Price promoted to medical director from April 9, 1899; Surgeon G. M. Pickrell promoted to surgeon from September 19, 1899; Assistant Surgeon R. Spear ordered to duty in connection with the naval recruiting rendezvous, Philadelphia, Pa., January 9th. January 4th.—Pharmacist J. N. Hurd ordered to duty at the Key West naval station, January 11th.

A New Hospital in Brooklyn.—The new St. John's Long Island City Hospital was blessed by Bishop McDonnell last Sunday. The building is of brick, is five stories high, and comprises a main structure and a wing with an extension in the rear containing the kitchens and laundry. In the main building on the first floor are the bishop's room and the children's room, while in the wing are the rooms of the house staff, and a suite of rooms for visiting clergymen. Private rooms for patients are on the second floor, while the women's ward occupies the wing. The third floor is taken up by the medical ward and the fourth floor by the surgical ward and nurses' rooms, while the operating-room is on the fifth floor. The patients will be moved from the old building the latter part of the month.

An Invalid Will.—The surrogate has refused probate of a will executed recently by an old woman one hour before her death. The will was signed by a mark, and it is asserted that the woman was kept alive long enough to sign it only by injections of strychnine and brandy. By the terms of the will $1,000 was left to the nurse, and the remainder of the estate, about $19,000, to the attending physician.

The Chief of the Sanitary Corps in the Boer Army is a German, Dr. M. Reinhard, from Bavaria.

An Australian Hospital Corps for South Africa.—The government of New South Wales has decided to send a field hospital corps and a battery of artillery to South Africa in addition to the mounted contingent.

A Case of Iodoform Poisoning in an Infant Two Weeks Old.—We have received a report of a case with the above title, the author of which omitted to send his name. If he will declare himself we shall be pleased to publish the case.

Obituary Notes.—DR. WILLIAM ALEXANDER HAMMOND died very suddenly at his residence in Washington on January 5th. He was born at Annapolis, Md., August 28, 1828, and was graduated from the University Medical School in this city in 1848. He entered the medical service of the United States army in 1849, but resigned in 1860 to accept the professorship of anatomy and physiology in the University of Maryland. Upon the breaking out of the civil war, however, he re-entered the army, and in April, 1862, was commissioned surgeon-general. He was later tried by court martial for irregularities in the award of contracts, and was dismissed from the army in 1864. While surgeon-general he established the Army Medical Museum, and suggested the plan of the "Medical and Surgical History of the Rebellion." After dismissal from the army he began practice in this city. He was professor of mental diseases in the Bellevue Hospital Medical College and later in the University Medical School. He was one of the founders of the New York Post-Graduate Medical School. In August, 1879, he was restored to the rank of surgeon-general U. S. A., retired, but without pay. Dr. Hammond was a man of undoubted ability, but his methods were not always in conformity with the unwritten code of professional ethics.

DR. JOSEPH E. ARROWSMITH died at his home in Keyport, N. J., on January 3d, at the age of seventy-seven years. He was a graduate of the University Medical School in this city in the class of 1844, and had practised in Keyport for over half a century. He was a member of the New Jersey State Medical Society and of the Monmouth County Medical Society, and was a consulting physician to the Monmouth Memorial Hospital in Long Branch.

DR. ROBERT H. HINE died of nephritis at Philadelphia, on December 30th, at the age of twenty-seven years. He was graduated from the dental department of the University of Pennsylvania in 1892.

DR. JOSIAH REEVES died at Medford, N. J., on December 25th, at the age of fifty-eight years.

DR. WILLIAM CROMWELL MCFETRIDGE died at Philadelphia on January 3d, of pulmonary tuberculosis, at the age of thirty-five years. He was graduated from the medical department of the University of Pennsylvania in 1886.

Progress of Medical Science.

New York Medical Journal, January 6, 1900.

Injuries of the Kidney and Traumatic (Parenchymatous) Nephritis.—T. J. Yarrow briefly states the causes, symptoms, and results of contusion and laceration of the kidney, and gives the history of a personal case, that of a boy aged seven years, who was run over by a coal cart, the wheel passing over the right leg and region of the right kidney. Immediate catheterization gave two ounces of normal urine, but two hours later he voided twelve ounces of bloody urine. His temperature was at first subnormal, but he soon developed a febrile movement, never over 100.6° F. In the course of six weeks he had entirely recovered. A very complete series of urinary examinations was made and is recorded in full. In addition to the usual findings, crystals of hæmatoidin were observed on several occasions. Yarrow believes that cases of nephritis due to trauma are far more common than is generally supposed.

The Limitations and Value of Fluoroscopic Examinations.—C. L. Leonard states that this method is dependent upon the personal equation of the observer, and differs from the skiagraphic method of employing the Roentgen rays, in that the picture on the screen transfers the image through the eyes and, while forming a mental picture, produces no mechanical record. Hence we have no fixed data in comparing impressions made at one time with those made at another. He believes that the value of the *x*-ray lies not in its power to penetrate everything, but in distinguishing between the less dense tissues, and thus enabling us to study organs and viscera that are hidden from ordinary vision. The fluoroscope is incapable of detecting these shades of difference, and does not mechanically register what it shows.

Hemorrhoids: The General Practitioner and the Ubiquitous Charlatan.—J. W. J. Doyle calls attention to the fact that rectal diseases are frequently prescribed for by the physician without the making of any systematic examination of the patient. But little value is to be attached to the patient's own statement of his symptoms. These may all be referred to the rectum, but examination may show affections of the uterus and bladder, stricture of the urethra, prostatic troubles, and various abdominal growths. Rectal examinations are not extraordinarily difficult and do not require any complicated apparatus. The vast majority of diseases within the rectum can be detected by the educated finger, the speculum being but seldom required.

On a Grave Possible Error in Skiagraphy.—Carl Beck shows by several illustrations the necessity of making skiagraphs in cases of suspected fracture, not only in an antero-posterior but also in the lateral direction. The picture of either one alone may lead to serious errors in diagnosis.

Monstrum per Defectum.—A. Moore figures and describes a monstrosity recently seen by him. It was delivered as the result of a miscarriage, and was a case of acrania with pseudo-encephalocele.

Report of a Few Cases of Chronic Empyema of the Antrum of Highmore, by A. W. De Roaldes. See Medical Record, vol. lv., p. 842.

The Sudan III. Stain for the Tubercle Bacillus.—By D. M. Cowie.

The Medical News, January 6, 1900.

Latent Infection and Subinfection, and the Etiology of Hæmachromatosis and Pernicious Anæmia.—J. George Adami concludes from his own experiments and those of others that, normally, leucocytes pass through the mucosæ on to the free surface of, more especially, the alimentary tract. These leucocytes pass back between the epithelial cells bearing foodstuffs, solid particles, and bacteria. This action of the leucocytes is increased during digestion: after their return they pass either into the lymphatics or the portal venules. It can be demonstrated that even in the healthy liver and kidney in a large number of cases, at least in the rabbit, a certain number of living microbes are present at any one moment. It is probable that in ordinary health a certain number of bacteria pass either through the thoracic duct or through the liver into the systemic blood. Apart from this latent infection Adami believes in the intermediate condition—"subinfection," a condition of chronic inflammatory disturbance. He also thinks hæmachromatosis and pernicious anæmia to be of bacterial origin.

The Principles of the Treatment of Fractures by Systematic Movements and Massage Without Apparatus for Immobilization.—Lucas-Championnière enumerates the advantages of his method of treating fractures. Moderate movement favors the repair of fragments of bone. Where movement is permitted the callus will be greater in quantity, will be more solid, and will be more rapidly thrown out. Moderate movement preserves the vitality of the limb as well as the suppleness of the articulations, muscles, and tendons. It prevents muscular atrophy. To this passive movement should be added massage, which should never cause pain. Threatened deformity is the only contraindication to the application of this treatment to all fractures.

Some of the Causes of Failure to Relieve Asthenopia and Allied Symptoms.—F. W. Marlow divides these cases into two main classes: (1) curable; (2) incurable. The curable cases fall into three groups: (*a*) In which the failure is the fault of the patient—often from carelessness in wearing the prescribed glasses. (*b*) Fault of the oculist, from failure to correct astigmatism or latent hypermetropia with sufficient accuracy; or in over-correcting myopia; or from neglecting to consider the influence of latent strabismus. (*c*) Fault of the case, due to extreme latency of errors of refraction and equilibrium. Incurable cases are of two classes: (*a*) Congenital asthenopes. (*b*) Cases with symptoms due to organic disease of eye or brain or to some general disease.

A Series of Cases of Pistol-Shot Wounds of the Head.—Charles Phelps reviews nine cases of this nature, and says that at present there is no doubt that all cranial pistol-shot wounds should be carefully explored, and as far as possible both the bullet and fragments removed.

A Case of Polydactylism.—A. L. Benedict reports this case, giving illustrations of the deformed hand and foot. The patient is a Jew. Each extra digit has a distinct articulation with the fifth metatarsal or metacarpal bone, respectively, the tendons being apparently the same as for the fifth digits.

Aseptic Catheterism.—Carl Beck states that the precautions to be observed in catheterism are: sterilization of instruments, the hands of the surgeon, and the field of operation.

Journal of the American Medical Ass'n, Jan. 6, 1900.

Ophthalmia Neonatorum.—Dudley S. Reynolds says that ophthalmia neonatorum means infectious conjunctivitis, always the result of contagion, very rarely, if ever, occurring in the process of delivery, the infecting agent being introduced by unskilled handling of the eyes by the nurse, or in an attempt to practise the Credé method or some similar mode of prevention. The clinical forms of the disease may be divided into mucopurulent and gonorrhœal. The only efficient mode of prevention is that which avoids infection, and the methods of Credé and others cannot be too strongly condemned. In the treatment the thing to be constantly borne in mind is the necessity for frequent and thorough washing away of all inflammatory matters from the surface of the affected membrane. "He who cleanses well cures well," must be the physician's motto.

Appendicitis from a Medical Standpoint.—I. N. Love argues strongly against the administration of sedatives in cases of severe abdominal pain until an approximate diagnosis has been reached, which cannot be done without free lavage and evacuation. The diagnosis once reached, appendicitis is to be regarded as a surgical case calling for—and this is the author's main contention—the interference of the trained abdominal surgeon. He claims for ideal surgery a mortality of one or two per cent. Failing the special abdominal surgeon, he would advocate medical or expectant treatment rather than place these cases in the hands of average general surgeons or practitioners.

Observations on Asch Operation for Deviation of Cartilaginous Septum.—Max Thorner describes the instruments devised by Asch for correction of deflections of the cartilaginous septum, and explains their use in full detail. There have been a large number of cases subjected to this operation since it was first performed in 1882, and with results almost uniformly good. The writer wishes to emphasize the fact that in his personal cases the operation has proved signally successful for the relief of scoliosis of the nose, which is often more distressing to the patient than the stenosis.

The Tuberculin Test, and the Need of a More Complete Diagnosis of Tuberculosis.—Charles Denison urges the need of earlier and better diagnosis of tuberculosis, and claims that among the most accurate means to this end is the tuberculin test. He says the experience of veterinarians in every State of the Union and of divers physicians all over the country was amply sufficient to convince an over-cautious profession of the comparative harmlessness of this test. He thinks that boards of health, dispensaries, and hospitals ought specially to be supplied with this means of diagnosis.

A Case of Chronic Inversion of the Uterus; Spontaneous Reduction After Three Years.—A. F. Jonas reports a case in which, after renewed and prolonged but futile efforts at reduction, the patient was dismissed. Subsequently spontaneous reduction and complete regeneration of the uterine mucous membrane took place, the woman passing through a normal confinement.

Continental Views of Alcohol in Therapeutics.—T. D. Crothers says the therapeutic use of alcohol in Europe is not so universal as is generally supposed. He concludes that the use of alcohol as a therapeutic drug must be modified, and that in the near future the agent will be put aside as worthless and dangerous.

Appendicitis with Gangrene and Rupture of Appendix and Cæcum.—Harry Greenberg reports a case of this description in which operation resulted in recovery.

Modern Therapeutics.—Warren B. Hill discusses modern therapeutic methods, especially the use of antitoxic serums and glandular extracts.

From Saddlebags to Pocketbooks.—By B. T. Whitmore. See MEDICAL RECORD, vol. lv., p. 892.

Laminectomy.—By John C. Munro. See MEDICAL RECORD, vol. lv., p. 835.

Boston Medical and Surgical Journal, January 4, 1900.

Epistaxis.—Frederic C. Cobb says that the local causes of epistaxis are apt to be ulcerations of the blood-vessels from scabs and crusts on the septum due to irritation by deflected septum, new growths, and operations for sarcomata. General causes are plethora and anæmia, hemorrhagic diathesis, acute fevers, vicarious menstruation, kidney disease, syphilis, phthisis, and alcohol. The bleeding point on the septum may be cauterized with chromic acid or the galvano-cautery, after cocainization. Suprarenal extract may be tried. Plugging should be done with strips of gauze along the floor of the nose, the Eustachian prominence not to be occluded.

Nitrate of Silver in Hyperchlorhydria.—M. P. Smithwick says that, to do the best for patients suffering from this disorder, one must treat them as neurasthenics, and assist them to live without unnecessary expenditure of nervous energy. Proteid diet has been found suitable in severe cases. Medicinal treatment is discouraging as regards cure. The administration of silver nitrate, one-fourth grain in a half ounce of distilled water twenty minutes before breakfast, has been followed by good results, markedly diminishing gastric sensitiveness. The necessary use of the stomach tube is a disadvantage, and the possibility of argyria must be kept in mind.

Three Unusual Cases of Angioneurotic Œdema in Infancy.—John Lovett Morse, stating that the usual seats for this somewhat unusual affection are the lips and cheeks or the external genitals, reports three cases in which the location of the swelling was the arms and hands. In the first case there was no known exposure or injury. In the second case an over-cold bath is supposed to have caused the trouble in one attack, and various exposures to cold the subsequent attacks, while in the third case no cause was found, but the trouble appeared most markedly in cold weather.

What Position Shall Universities Take with Regard to Investigations?—Thomas Dwight thinks that it is not the duty of universities either to force or urge original investigation upon students, which, however, should be on hand for the very zealous. Prizes should not be too common, but there cannot be too many scholarships for deserving men. In addition a sum of money should be placed in the hands of the professor at the head of each scientific department, to be spent for the good of that department, including publication.

Appendicitis in a Hernial Sac.—Benjamin Tenney reports a case in a woman aged seventy-nine years who was successfully operated upon, the patient making a good recovery.

Quantitative Analysis of the Gastric Contents.—Henry F. Hewes gives an improved method for this analysis, for use in clinical work.

Philadelphia Medical Journal, January 6, 1900.

The X-Ray Diagnosis of Nephrolithiasis.—Charles Lester Leonard has devised a method by which he claims he can make the absolute negative as well as the positive diagnosis in all cases of suspected renal calculus. This he does by using rays that will differentiate between the shadows of tissues less dense than the least dense calculus.

White Gangrene.—George G. Hopkins discusses, under this title, *x*-ray injuries which result from the destruction of the nerve supply of the affected tissue. He says they can be avoided by using proper apparatus, making a not too long exposure, and having not too small a distance between the tube and the object skiagraphed.

Practical Points in the Use of the X-Ray.—Louis A. Weigel insists upon the necessity for accuracy in *x*-ray work. He says there is often a striking difference between the image as seen with the fluoroscope and that on an *x*-ray negative, and the former is of limited utility as an aid to diagnosis.

I. A Bullet in the Popliteal Sphere. II. A Case of Dilated Œsophagus.—W. W. Keen reports two cases showing the value of the *x*-rays in diagnosis. In the first case, however, the bullet seemed to be posterior to the head of the tibia, yet was, in fact, embedded in the bone.

The Practical Use of the Radiograph and Fluoroscope in Diseases of the Lungs.—T. Mellor Tyson and William S. Newcomet are inclined to believe that errors in mistaking normal processes for pathological ones, in *x*-ray diagnosis, are due to hasty observation or want of experience.

The X-Rays in the Study of the Heart Reflex.—Albert Abrams says the heart reflex (contraction of the myocardium induced by irritation of the skin in the precordial region) is best studied with the fluorescent screen approximating the anterior chest-wall.

The Technique of X-Ray Work.—Arthur W. Goodspeed thinks that some of the now antiquated features of *x*-ray work are excellent, and attributes the special merit of much of his work to the constant adherence to one or two of these features.

Foreign Body, Chisel, Embedded in the Naso-Pharynx and Posterior Pharyngeal Wall.—Cary B. Gamble, Jr., and L. M. Tiffany report this case, in which the chisel was located by the *x*-rays, and was successfully removed.

Two Cases of Simultaneous Fracture of the Patellas, Treated by Wiring the Fragments.—J. S. Wright advises delay in wiring a fractured patella, his plan being to wait two weeks and sometimes four before operation.

The X-Rays as a Diagnostic Agent in Pulmonary Diseases.—J. Edward Stubbert holds that the fluoroscope is an accurate agent for corroborating and extending diagnosis made by ordinary methods.

X-Ray Examinations in Diseases of the Chest.—Francis H. Williams reports on the work of this kind he has done at the Boston City Hospital and in private practice.

An X-Ray Demonstration of Some of the Effects of Shoes and Stockings upon the Human Foot.—H. Augustus Wilson shows a number of *x*-ray pictures of deformed feet.

The Skiameter.—A. W. Crane describes an instrument by which he seeks to measure and record the density, size, shape, and movements of the fluoroscopic shadows.

Treatment of Lupus by X-Rays.—Philip Mills Jones reports two cases of lupus successfully treated by *x*-ray exposures.

The X-Ray in Military Surgery.—N. Senn says the *x*-ray is an indispensable diagnostic resource to the military surgeon.

The Use of the X-Ray in Orthopædic Surgery.—Robert W. Lovett presents a number of *x*-ray pictures of arthritic disease.

The Lancet, December 30, 1899.

Measures taken at Tor and Suez against Ships Coming from the Red Sea and the Far East.—M. A. Ruffer describes the organization of the sanitary department of Egypt, and speaks particularly of the measures taken to prevent the transmission of cholera and the plague. The measures differ as the ship may carry pilgrims or ordinary travellers. In former years the danger was minimized by the long period of travel required by the camel caravans, but now that rail and steamboat are used by the pilgrims, the danger is greatly increased, as the journey is so quickly made. The means of transport for these devotees is totally inadequate, and there is frightful overcrowding with all its filth and want of sanitary arrangements. Details of quarantine routine are given, but the people reach the quarantine stations in such enormous numbers that it is difficult if not impossible to carry out all the official regulations. In addition to the most thorough cleanliness possible, each pilgrim passes under the direct observation of a physician who takes his pulse, examines all the superficial glands, and carefully inspects the tongue. The incubation period of plague does not exceed five days. In a really bad case the patient is so sick that it is not likely to be overlooked. With cholera, the case is somewhat different, as the vibrio choleræ frequently persists fifty days or more in the dejections of those who have had cholera. Pilgrim's diarrhœa, so-called, includes every form of intestinal derangement from typhoid to cholera. Hence it is extremely difficult to detect true cholera cases, as it is quite impossible to make bacteriological examinations in every case. Fear of delay at quarantine leads to the concealment of many cases. Hence Ruffer expresses the belief that all measures for ships going through the canal should be confined to landing of the sick and the disinfection of the sick person's quarters and linen. It is better to do a little and do it well, than to attempt a great deal and do most of it imperfectly.

The Treatment of Surgical Tuberculous Affections.—W. Watson Cheyne devotes the third Harveian lecture to the consideration of genito-urinary tuberculosis, discussing in turn castration, epididymectomy, and operations on the prostate, bladder, and kidney. Various operative details are given, the author preferring epididymectomy, the method of Bardenheuer, who was the first to describe the operation. This operation is often to be preferred to castration. One cannot be sure that the removal of one testis will arrest the disease. The loss of both testes exercises a very deleterious effect on the patient. Apart from their generative function, they exert by means of their internal secretion a very great influence on the well-being of the patient. Moreover, there is reason to believe that after removal of both testes patients succumb more rapidly to the attacks of the bacillus. These objections to castration are to a great extent met by the operation of epididymectomy.

Some Notes on Sero-Therapy.—H. W. Mills records the following clinical experiences: (1) Tetanus in a boy aged eighteen years following lacerated wound of the foot. There were symptoms of tetanus on the sixth day, with injection of anti-tetanic serum, followed by a fatal result in twenty-four hours; at that time (1897) intra-cerebral injections were not in vogue and the serum was injected under the skin of the abdomen. (2) Puerperal fever treated with anti-streptococcic serum, 140 c.c. being given within a period of five days. It seemed to control the septic features of the case, but the patient died from syncope coming on after incautious over-exertion. (3) Antitoxin in twenty-seven consecutive cases of diphtheria, all of which ended in recovery. Six patients showed post-diphtheritic paralyses, while five had rashes from the seventh to the thirteenth day. A most emphatic indorsement is given to the practical utility of immunizing injections.

Extensive Mediastinal Emphysema in a Fatal Case of Laryngeal Diphtheria.—W. Ewart and H. B. Roderick report the case of a girl aged five years, illustrating a complication to which diphtheria of the larynx and trachea is liable in spite of tracheotomy and of antitoxin, and the fatality of which is probably attributable to the cardiac and pulmonary embarrassment set up by the increasing distention of the areolar tissue of the anterior and posterior mediastina and of the root of the lung.

Anatomical and Age Distribution of the Tineæ of Southern Assam.—S. A. Powell, who has practised eleven years in Assam, says that he has never seen a single case of ringworm of the scalp, but that nearly every one has at some time or other tinea of the body. Tinea of the nails is very common in that country. The article is a study of 1,407 cases of different varieties of the disease.

Our Position and Outlook.—An inaugural address by J. A. Lindsay at the opening of Queen's College, Belfast.

British Medical Journal, December 30, 1899.

The Essential Toxic Symptoms of Diphtheria.—John Biernacki draws his deductions from notes of fatal cases in which the toxic symptoms are extreme, as they obviously afford the best material for observation, taking care to exclude those cases in which the directly toxic element is masked by secondarily induced phenomena. He says that for a time the only symptoms are those ascribable to sore throat and fever, the first specific signs being undue pallor, moderate compressibility of the pulse, and lassitude. In a few days the pallor becomes more marked, the pulse more compressible, and the pyrexia less. Later the pulse is irregular, the urine is diminished in quantity, and the extremities are cold. Toward the end the surface of the body is blanched and cold, the temperature subnormal, and the radial pulse disappears. Other symptoms are jactitation and dimness of vision. These symptoms are accompanied by a fall in blood pressure, and are probably caused by it.

A Case of Malignant Pustule: Necropsy, with Bacteriological Investigations.—George H. Temple reports the death from malignant pustule of a seventeen-year-old girl. At the autopsy microscopical examination failed to reveal bacilli in the pustule or any of the organs. Potato cultures, however, were made from a clot found in the pulmonary artery, and resulted in a sufficient growth to enable a diagnosis of anthrax to be made microscopically. Inquiry in the village where the patient had visited revealed that five animals had died under somewhat suspicious circumstances two days before the girl's visit. Three points are noted: the rarity of cases of malignant pustule in women, the possibility of such cases being overlooked, and the great difficulty of detecting anthrax among stock before an epidemic occurs.

Poisoning by the Application of Glycerin of Belladonna.—H. P. Joseph reports a case of a woman who after being delivered of a still-born child complained of pain in the breasts. An application of glycerin of belladonna was ordered, resulting in all the symptoms of belladonna poisoning. She recovered slowly after a hypodermic injection of liquor strychninæ.

A Case of Membranous Conjunctivitis Treated by Antidiphtherial Serum.—A. D. McQueen reports a case in which bacteriological examination of the membrane detached from the eye showed diphtheria bacillus. The case was then treated as one of true diphtheria, with the result of prompt recovery.

Piperazin in Gout.—William Fearnley reports a case showing the good results of piperazin in gout. He says that the expense and trouble of taking this drug are its only drawbacks, but for the gouty he considers it as necessary as their daily bread.

The Treatment of Diphtheria.—A. Jefferis Turner sums up this matter by saying that the treatment of diphtheria consists in the administration of antitoxin early and in sufficient dose.

Surgical Treatment of Tuberculous Diseases.—By W. Watson Cheyne. See MEDICAL RECORD, vol. lvii., p. 67.

Lectures on Pharmacy and the British Pharmacopœia.—By Nestor Tirard.

Medical Press and Circular, December 27, 1899.

On the Examination of Sick Children.—Langford Symes gives an abstract of the mode of procedure in history taking and examination of the naked child. The order he recommends is: facies, head, frame, reflexes, eyes, glands, abdomen, heart, lungs, spine, neck, mouth, nervous system. The following are the chief points to be attended to so far as the nerves are concerned: (1) Motor phenomena; (2) reflex phenomena; (3) sensory phenomena; (4) trophic phenomena; (5) electrical phenomena; (6) bladder phenomena; (7) rectum phenomena; (8) mental capacity; (9) speech (aphasia, nasal speech, stammering, idioglossia, or even dumbness); (10) power of sitting, standing, walking, reading, writing, or singing. He finds that some children with cerebellar tumor can sing very well. The advantage of the plan he gives is that the hands once placed upon the child need never be removed until the entire investigation is complete. Examination is more difficult than in the adult.

Gastric Ulcer: Perforation, Recovery; Ulcerative Endocarditis; Death.—W. H. Carthew Davey reports the following case: A woman, aged twenty-two years, was attacked with sudden abdominal pain and vomiting of black-colored fluid. Treatment was by morphine hypodermatically and rectal feeding. In three weeks peptonized milk was retained by the stomach and improvement continued. At the end of a month parotitis developed with facial paralysis, first on one side, then on the other. General sepsis, ulcerative endocarditis, and death followed after four months.

Case of Cæsarean Section.—G. Cole Baker operated on a woman who had borne living children, though the true conjugate was but 6 cm., having been pregnant ten times before. The child weighed nine pounds. The mother was up on the twenty-eighth day.

Cases of White Swelling of the Knee.—A. B. Judson describes ten cases. He does not insist on absolute fixation if the knee is capable of full extension.

Surgical Treatment of Tuberculous Diseases.—By. W. Watson Cheyne. See Medical Record, vol. lvii., p. 67.

Munchener med. Wochenschrift, December 19, 1899.

Experiments in Hand Disinfection.—Paul and Sarwey come to the following conclusions on this subject: Contrary to Ahlfeld's assertion that the normal "every-day" hand yields fewer bacteria after its disinfection by means of hot water and alcohol, and that after a longer soaking in warm water, combined with energetic mechanical manipulation, its bacteria are decreased, these investigators are certain that the hands are not freed from bacteria by hot water and alcohol disinfection. They add that the question as to whether hot water and alcohol disinfection is superior to other methods can better be answered after experiments shall have been made with artificially infected hands, and after other methods shall have been thoroughly tested.

A Case of Acromegaly Complicated by Symptoms of Raynaud's Disease.—A. Boettiger gives the history of a case in which the diagnosis of acromegaly is absolutely certain. Of especial interest, however, is the color of part of the skin of the fingers and hands, which was bluish-black, while here and there were scattered brick-red patches of irregular outline. The hands felt cold and moist. Tactile sensation was normal for the hands, sensation of pain being dulled. The skin temperature was subnormal. Heat and cold were clearly distinguished. The faradic sensation of pain was altogether absent in the skin of the fingers. Reflexes were normal. For both affections there seems to be a toxic etiology, the poison probably not coming from without, but being elaborated in the body itself. Autopsy frequently shows the same alterations in the vessels in both diseases.

The Value of Urine as a Culture Medium for the Diagnosis of Typhoid Fever.—Ernst Unger and Ernst Portner give the following points as important in relation to cultures made for diagnostic purposes. The lack of long-thread colonies is a proof of the absence of typhoid. Numerous long-thread colonies prove the presence of typhoid. Shorter-thread colonies are of use for diagnosis only in combination with the clinical symptoms of typhoid. Urine as a culture medium is a great advance in bacteriology, for since up to this time the proof of typhoid bacilli in the stools was difficult and required from four to five days, they can be demonstrated in the urine in from two to three days, and with much greater certainty.

Dionin.—Meltzer says that dionin has a milder analgesic affect than morphine, and on the other hand a more powerful and lasting effect than codeine, having neither the bad features of the above preparations nor the bitter taste of peronin.

The Effect of Dionin and its Use in Diseases of the Respiratory Organs.—Th. Janisch asserts that dionin induces sleep quite promptly in nearly all cases, and is of the greatest use in chronic bronchitis, emphysema, asthma, and phthisis.

Results of Vaccination in the Kingdom of Bavaria in the Year 1898.—By L. Stumpf.

Berliner klinische Wochenschrift, December 18, 1899.

Sequelæ of Singers' Nodes.—A. Rosenberg has noticed in the cases of vocalists suffering from this affection a certain change in those individuals who do not give themselves the proper respite from continuous vocal exertion. The circumscribed nodule seems to disappear, and in its place there is noticed a broadening of the cord itself, so that it presents a convex rounded edge. Proper rest restores the characteristic nodular appearance. When the patient phonates, the cords approximate normally in their anterior half, but not in the posterior owing to the convexity mentioned, so that at the posterior end of the glottis there is a triangular cleft made at the expense of the affected side. If both sides are affected this is symmetrical and of course larger. R. claims that by noting this appearance of the cords he can tell whether or not his directions as to vocal rest, etc., have been observed by these patients.

Changes in Circular Insanity.—A. Pick treats of certain changes in type of circular insanity which he thinks have been gradually taking place. These changes are particularly interesting as demonstrating that mental diseases are not all stereotyped in character, but that they undergo gradual changes in type just as do the organic affections.

Congenital Complete Bilateral Anosmia.—Placzek reports such a case occurring in a woman aged sixty years, and claims that it is the second on record. He also states on the authority of Roscoe that the famous Lorenzo di Medici was similarly affected.

La Riforma Medica, December 13-18, 1899.

Pulmonary Hypertrophy, Ectasy, Swelling, and Emphysema.—Edoardo Maragliano calls attention to the fact that many pulmonary conditions have ordinarily been erroneously grouped together under the name of emphysema. Among these are a physiological hypertrophy, vicarious emphysema, and pulmonary swelling. In true emphysema there is alteration of the lung tissue and increase of endo-alveolar pressure. Moreover, true pulmonary emphysema is always generalized and diffuse in both lungs, whereas hypertrophy and dilatation are localized in certain determined areas. An exact diagnosis in these cases is necessary to intelligent and successful treatment.

Microscopical Findings in a Case of Idiopathic Partial Neuritis of One Hypoglossal Nerve.—Alessandro Marina found in the right hypoglossal nerve of a patient who had for four years suffered from unilateral glossoplegia and hemiatrophy of the tongue, and who died of pneumonia, microscopical signs of a primary neuritis of the middle third of the nerve. Only a third of the nerve bundles were affected, the rest being absolutely healthy. This demonstrates that partial paralysis of an area innervated by a single nerve trunk does not alone indicate a central affection.

Researches upon the Pathogenic Action of the Casein Ferments.—R. Jemma concludes from his experiments that the usual ferments of casein belong to the bacillus subtilis group, which exhibits no pathogenic action in animals used for laboratory experiments; that among the ferments belonging to the mesentericus vulgatus group we find some endowed with pathogenic action upon the intestinal mucosa. Injected into the peritoneum, the circulation, and subcutaneously they are inactive. That the bacillus butyricus of Hüppe and the varieties related to it, isolated from milk, are always non-pathogenic.

Methylene Blue in Epilepsy.—Giuseppe Paoli used this remedy in nine cases with favorable results. It is best given by the mouth in pills ot 0.30 each, twice a day.

French Journals.

The Danger of Sexual Connection in Inflammatory Affections of the Uterus and Its Adnexa.—René Belin reports an observation of double pyosalpinx in which two double pockets were plainly made out by manual palpation before the patient entered the hospital. A laparotomy done at once revealed the presence of but one of these tumors, the other having ruptured before operation. It was subsequently ascertained that after the first consultation and on the eve of entering the hospital the woman had had coitus with no less than three of her friends, in the last of which she experienced a sensation like a tear, followed by severe pain. The author believes that violent coitus is often accountable for ruptured tubes and general peritonitis of obscure causation.—*Journal de Médecine de Paris, December 17, 1899.*

Subcutaneous Injection of Gelatinized Serum in Hemorrhagic Variola.—Boy-Teissier, in an epidemic just now raging at Marseilles, has been led, by the observations of Costinesco in purpura hemorrhagica, to try injections of gelatin in the hemorrhagic form of smallpox. In one series of seven cases, two of which were very severe, he injected a a single sitting 200 gm. of gelatinized artificial serum in the strength of two per cent. Six of the patients died, and one recovered. No abscesses resulted, nor was there even any redness of the skin. In a second series of thirteen cases, three of which were fulminating and ten simple hemorrhagic, he injected 200 gm. at two sittings, of the same strength. The three severe cases ended fatally, and among the milder ones there were two deaths and six recoveries, while at the time of the report two patients were convalescent without complications. The injections were begun with the onset of premonitory signs, namely, epistaxis, hemorrhagic tint of the lids and conjunctiva, and a violaceous tint of the integument. Three abscesses were caused by the injections in this series.—*La Presse Médicale, December 16, 1899.*

The Indication for Cæsarean Operation Compared with Symphyseotomy, Craniotomy, and Premature Artificial Delivery.—Fancourt Barnes believes that the limits of Cæsarean section may be extended, since the mortality, which before 1880 was 81.2 per cent., has gone down to from 8 to 6.8 per cent. These results are due entirely to improvement of the technique of abdominal operations and uterine suture. The mortality to the mother in premature artificial delivery is one or two per cent., while that of the infant, on the contrary, is thirty-three per cent. He concludes that symphyseotomy has not proven its reason for existence, and he cannot help believing that the eminent men who have sung its praises will, in the future, come to abandon it. Premature artificial delivery will, within certain limits, always have a useful place in obstetrical operations. After an attentive study of the more recent publications upon Cæsarean operation, he has come to believe that it is an operation both scientific and justifiable, and that it will be carried out in the future in many more cases than hitherto.—*Journal de Médecine de Paris, December 17, 1899.*

Triple Stricture of the Intestine of Neoplastic Origin: Entero-Anastomosis.—P. Goullioud reports an observation in which a laparotomy revealed three distinct strictures in the intestine of a woman, thirty-three years of age, due to cancerous growth as indicated by the examination of mesenteric ganglia removed at the operation. The reason that operative procedures for occlusion or intestinal obstruction still give such undesirable results is because they are often undertaken at too late a period. In the case reported the resection of 50 cm. of the small intestine would have been necessary, without taking into account the enormous infiltration of the mesenteric ganglia. The operator, therefore, did an entero-anastomosis, the immediate result of which was good, but the treatment of the case had been undertaken at too late a period to be of permanent benefit.—*Lyon Médical, December 16, 1899.*

Premorbilliform Erythemas.—Eugène Deschamps relates a series of seven observations in which erythema of short duration, sometimes of the measles type and sometimes of the scarlatina type, had been observed by him and others shortly before the outbreak of measles upon the skin. He also reviews the erythematous eruptions which have been described as following shortly after measles. While these eruptions are habitually without serious consequence so far as the outcome of the disease is concerned, they seem, however, to furnish a precise indication for the necessity of disinfecting the child's nose and throat and of supervising the state of his digestive organs.—*La France Médicale, December 22, 1899.*

Eye-Reflexes Considered in Relation to Recruiting for the Army.—F. Lagrange believes that many men could be enlisted for the army who are now rejected because of defective sight. As to the question of astigmatism, he thinks it a simple matter, with the present use of the skiascope and ophthalmometer, with which every military hospital should be supplied, to test the eyes and accept those for whom correcting glasses can be given. Astigmatism should not be given as the reason for exclusion of many cases which can be readily brought up to or above the medium. The higher degrees of abnormal vision due to astigmatism should cause exclusion because of the frequency of intra-ocular lesions.—*Le Bulletin Médical, December 16, 1899.*

A Case of Ludwig's Angina.—G. Marchese de Luna relates an instance of sublingual phlegmon in a man aged thirty-nine years, terminating fatally. He calls attention to the importance of early diagnosis, and believes that energetic surgical treatment is the only one of utility. In the present instance he was not permitted to operate at the time he made the diagnosis. General infection supervened, with pneumonia in the last stages proving the presence of a general infection.—*Gazette des Hôpitaux, December 19, 1899.*

Transmission of Tuberculosis by Means of Postage Stamps.—Busquet relates an instance of a soldier admitted to the hospital for tuberculosis of the lungs, who was a collector of postage stamps, which he was in the habit of fastening in albums almost daily, either moistening the stamp itself or strips of adhesive paper by applying them to the tongue, frequently exchanging these same stamps with other collectors. Cultures made from these stamps showed the presence of tubercle bacilli.—*Le Bulletin Médical, December 16, 1899.*

Rupture of the Tympanum following a Blow upon the Ear.—Paul Viollet reports the case of a married woman who received a blow upon the ear resulting in rupture of the tympanum, and recalls an instance of traumatic ecchymosis of the tympanum following a kiss upon the ear, reported recently by Thollon.—*Gazette des Hôpitaux, December 19, 1899.*

American Journal of the Medical Sciences, January, 1900.

On Splenic Anæmia.—William Osler reports fifteen cases of splenic anæmia, a term which indicates the two essential features of the disease. This series emphasizes the long duration of the affection. In all, the enlargement of the spleen, which was considerable, appears to have preceded the anæmia. In seven cases, hemorrhage from the stomach was the feature for which relief was sought. Watson explains hæmatemesis in enlarged spleen: "The stress of the congestion is continually felt in the submucous capillary system, and the hemorrhage, which is apt in such cases to occur from the loaded membrane, receives a simple solution upon principles almost purely mechanical." Ascites was present in three cases. In no case were the external lymphatic glands especially enlarged. Any grade of anæmia may exist. Melanoderma was seen in six cases. There was a relatively high blood count, relatively low hæmoglobin, and low leucocyte count. A differential diagnosis must be made from pernicious anæmia, splenic leukæmia, Hodgkin's disease with enlarged spleen, cirrhosis of the liver with enlarged spleen, alcoholic, syphilitic, and hypertrophic cirrhosis. The treatment is that of severe anæmia.

Report of Five Cases of Endocarditis Occurring in the Course of Tonsillitis.—Frederick A. Packard, in his report of these cases, believes them to have been pure examples of acute tonsillitis and pharyngitis, having no connection with rheumatism, the endocarditis arising as a direct consequence either of infection of the endocardium by micro-organisms, which gained entrance by way of the tonsils, or of structural change in the mitral leaflets, brought about by coagulation necrosis or other result of the chemico-vital action of toxins produced by micro-organisms present in the throat and absorbed from the inflamed tissues.

Facial Spasm and Its Relation to Errors of Refraction.—Stevens, in a report on facial spasm, says that the symptom picture differs but little in all forms, the spasm being usually confined to the distribution of the facial nerve. The etiology is often obscure, but may be from an affection of the nose or rhinopharynx or from cortical or subcortical disease. Ocular defect is more usually responsible. The refraction and muscle balance should be corrected and systematic after-treatment should be pursued.

The Relation of Migraine to Epilepsy.—William G. Spiller states that migraine, especially the ophthalmic form, is related to epilepsy. Generally, no convulsions are detected in migraine, though they may develop after many years. These cases may be regarded as abortive cases (formes frustes) of migraine that later become associated with epilepsy, or as abortive forms of epilepsy (sensory epilepsy) in which the convulsions later become apparent.

Report of a Family Outbreak of Trichinosis.—George Blumer and Leo Haendel Newman report nine cases of trichinosis in two families. Blood examinations showed an eosinophile leucocytosis, a relative decrease in the neutrophiles, and in many cases a decrease in the small uninuclear leucocytes.

Tracheal Diastolic Shock in the Diagnosis of Aortic Aneurism.—J. N. Hall holds that the crucial test of the value of this sign is in differentiating aneurism from solid thoracic tumor in cases not involving the chest-wall.

A Critical Summary of Recent Literature on Gonorrhœa in Women.—John G. Clark, in his review of this subject, lays stress on the chronic or persistent course of gonorrhœa.

Cystinuria and Its Relation to Diaminuria.—Charles E. Simon states that diamins have been encountered in the urine in cases of cystinuria, and in these cases only.

International Medical Magazine, December, 1899.

On the Relative Frequency of Hernia in the Sexes and the Various Types in the Female; a Statistic Comparison.—Thomas A. Manly states that hernia statistics are most unsatisfactory. Kingston says that for all ages the proportion of hernia is two males to one female. Cloquet concluded after large experience that ruptures are nearly three times more numerous in men than in women. After the age of forty-five years hernia has about the same frequency in both sexes. Heath says in the adult female the proportion of inguinal to femoral is about equal. Typical adult umbilical hernia is *par excellence* an infirmity of married women.

Obstructive Diseases of the Male Urethra.—J. D. Thomas enumerates the obstructive diseases (and obstructions) of the urethra as: Foreign bodies; acute prostatitis; false passage; rupture; stricture; spasm of the cut-off muscles; injury to, or in the neighborhood of, the anus; chronic hypertrophy of the prostate; small meatus; phimosis; pediculated tumors; congenital atresia. With very few exceptions, the various obstructive diseases all require different treatment—the method to be governed by the cause of the disease.

The Diagnosis of Iritis.—Walter L. Pyle says there should be no difficulty in differentiating iritis from conjunctivitis. The chief distinguishing points are: Discoloration of the iris when compared with its fellow; contracted, sluggish, or fixed pupil, turbidity of the aqueous, and ciliary injection. From acute glaucoma, the diagnosis is more difficult. Here, besides testing for increase of tension, we have the size of the pupil as a guide in iritis, more contracted than usual and perhaps fixed; in glaucoma, dilated and sluggish. Generally, in these acute inflammations satisfactory ophthalmoscopic examination is impossible.

Neurosal Conditions Involving Excessive Secretion of the Gastric Juice (Hyperchlorhydria, Hyperchylia, Gastroxynsis, Reichmann's Disease, etc.).—Boardman Reed states that the differential diagnosis of the forms of hypersecretion must turn almost entirely upon the chemical and microscopical examinations of the stomach contents. The diagnosis from gastric ulcer is not always easy. The diet should be carefully regulated, and a complete rest from mental occupation is most important.

The Importance of the Early Recognition of Carcinoma Uteri, and the Methods by which It is Attained.—E. E. Montgomery states that carcinoma uteri in its very early stages is quite amenable to treatment. When suspected, the surgeon should first try dilatation for digital exploration—the next step being microscopical examination of the tissues obtained either by excision of a specimen or by curettage.

Gall-Stone Crepitus and Friction, with Illustrative Cases.—J. M. Anders says that while the presence of gall-stone crepitus and friction in typical cases of cholelithiasis is corroborative, it is not essential to an absolute diagnosis. In irregular cases, either symptom often serves as a deciding factor.

Laboratory Methods of Diagnosing Tuberculosis: The Staining of Sputum.—W. Wayne Babcock describes carefully the technique of staining the tubercle bacillus by means of carbol fuchsin and Loeffler's alkaline methylene blue.

Journal of Experimental Medicine, November, 1899.

Experimental Investigation of the Treatment of Wounds of the Heart by Means of Suture of the Heart Muscle.—Charles A. Elsberg, from numerous experiments on animals, concludes that suture of a wound of the heart, as a final resort, is an operation worthy of consideration and often justifiable. In animals, and also in man, it is devoid of the danger of sudden arrest of the heart, unless Kronecker's coordination centre be injured. The suture should be an interrupted one of silk, if possible penetrating only the epicardium and superficial layers of the myocardium, and tied during diastole. No rules can be laid down, but each case must be considered separately as to indications for operation.

Acute Endocarditis Caused by Micrococcus Zymogenes.—William G. MacCallum and Thomas W. Hastings state that from a case of acute endocarditis of the aortic and mitral valves with infarctions in the spleen and kidneys, a micrococcus was twice isolated in pure culture from the blood during life and demonstrated after death in the valvular vegetations, infarctions, and other parts. It is small, and occurs mainly in pairs. It is pathogenic for mice and rabbits, causing abscesses or general infections. The authors, after much research into the nature of micro-organisms, feel justified in recognizing this organism as a new species, and from its fermentative properties name it "micrococcus zymogenes."

Chronic Interstitial Nephritis and Arteries in the Young.—N. G. Brill and E. Libman present a case whose chief points of interest are: (1) The occurrence of a very advanced primary chronic interstitial nephritis at the age of fourteen years. (2) Its presence in other members of the same family. (3) The extensive and marked arterial changes present. (4) The hemorrhagic diathesis, and the occurrence of a large hemorrhage in the mesentery. (5) The occurrence of calcified deposits in the liver. (6) The evident existence of latency of some cases of chronic nephritis in children.

Bacillus Pyocyaneus and Its Pigments.—Edwin O. Jordan separates this bacillus into four varieties: α, Pyocyanigenic and fluorescigenic (most common); β, pyocyanigenic only (rare); γ, fluorescigenic only (not uncommon, closely related to "B. fluorescens liquefaciens"); δ, non-chromogenic. The different varieties are not so plastic as is sometimes assumed, and cannot be readily converted into one another by subjection to varying conditions of life. The signification and correlation of the almost countless physiological variations among the members of this group in respect to growth in gelatin, behavior to temperature, indol production, etc., remain to be determined.

A Study of the Neuron Theory.—Martin H. Fischer claims that there is not independence of neurons, as anastomoses have been found, and that the dendrites may have a nutritive as well as a nervous function.

Fibro-Sarcoma of the Brain.—Alice Hamilton reports a tumor resembling glioma, but in which the fibrils were arranged in circumscribed masses, and took the differential stains for connective tissue. It was decided that it was an unusual form of fibro-sarcoma.

The Differentiation and Classification of Water Bacteria.—George W. Fuller and George A. Johnson call attention to several modifications which experience has led them to believe are of assistance in the study of water bacteria.

A Preliminary Note on the Fractional Precipitation of the Globulin and Albumin of Normal Horse's Serum and Diphtheritic Antitoxic Serum, and the Antitoxic Strength of the Precipitates.—By James P. Atkinson.

Leukæmic Lesions of the Skin.—Horst-Oertel describes leukæmic cutaneous nodules whose structure supports the theory that secondary leukæmic nodules are essentially composed of cells derived from the blood.

Lymphoma.—E. R. Le Count describes a small tumor which he considers to have been a benign, noninflammatory new growth of lymph nodes.

A Case of Addison's Disease with Simple Atrophy of the Adrenals.—Carlin Philips. See MEDICAL RECORD, vol. lv., p. 407.

Montreal Medical Journal, December, 1899.

Some Remarks on the Symptoms and Operative Treatment of Bronchocele, Especially in Relation to Graves' Disease.—Francis J. Shepherd, after enumerating the well-known symptoms of Graves' disease, reports several cases showing the effects of operative treatment. He considers it most important in choosing the form of operation to be guided by the nature of the case. Enucleation and the after-treatment are carefully described.

The Wisdom of Surgical Interference in Hæmatemesis and Melæna from Gastric and Duodenal Ulcer.—G. E. Armstrong, in defining cases of hæmatemesis suitable for operation, gives two classes: those, first, of frequently repeated small hemorrhages, which persist in spite of medical and dietetic treatment, and which threaten to destroy the life of the patient; and, secondly, those having large hemorrhage which, in spite of medical and dietetic treatment, recurs. He reports two successful cases.

Two Cases of Ephemeral Mania, Uncomplicated with Epilepsy, Intemperance, or Parturition.—T. J. W. Burgess records two cases of mania transitoria, both patients being women. The cause of the first was supposed to be the excitement of a railway journey and the consequent fatigue—this being her first experience; the second was caused probably by the shock of a sudden fright.

Goitre: Its Etiology and Incidence in the District of Montreal.—J. A. Springle, after summing up the causes which are generally considered as etiological factors of goitre, mentions some conclusions incident to Kocher's recent investigations. He believes that certain waters contain the materies morbi, emphasizing the fact that water from the so-called freshwater sandstone is particularly goitrous.

Notes from Practice in the Argentine Republic.—F. G. Corbin reports three cases: (1) Fecal fistula following pelvic abscess cured by operation; (2) nephrectomy without a ligature; (3) interstitial pregnancy mistaken for a myoma uteri; operation, recovery.

Endo-Enteric Suture.—E. Reavley describes the endo-enteric suture originated by F. G. Connell, illustrating the steps of this method by plates. He claims the following advantages: Rapidity, simplicity, only one line of union and that the shortest, less injury to the intestine, all intestinal walls included, and the greatest attainable strength.

A Case of Lues Venerea with an Unusually Protracted Incubation Period.—A. Mackenzie Forbes, in reporting this case, says that all penile abrasions, appearing both with and after urethral discharges, should be most carefully watched.

A Rare Surgical Case.—T. M. Calnek reports the case of an aneurism situated just at the trifurcation of the gluteal artery, the three main branches arising from the sac of the tumor.

Tuberculosis of the Flat Bones of the Skull.—A. Primrose reports such a case, observing that it is extremely rare and that it is apt to be confounded with syphilis.

Archives of Pediatrics, December, 1899.

A Case of Heart Lesions.—A. C. Cotton reports a case of this nature in a child eleven years old. The necropsy showed stenosis of the pulmonary conus; malformation of the pulmonary valve (two cusps); aneurism of the right ventricular wall; acute mural endocarditis; defective (perforate) ventricular septum; fibrinous pleuritis; old healed and recent metastatic abscesses of both lungs; cloudy swelling of the liver and kidneys; chronic splenitis and acute perisplenitis; general anæmia; anasarca, hydrothorax, hydropericardium, and ascites; panophthalmitis of the left eye. Bacteriological examination revealed the streptococcus pyogenes in the lungs and the vegetations, and adherent clots in and about the aneurism of the heart wall. The colon bacillus and two micrococci, which could not be identified, were also obtained from the lungs.

The Importance of Prolonged Rest in Bed after Acute Cardiac Inflammations in Children.—L. Emmett Holt asserts that there are three reasons why cardiac inflammations are likely to be especially serious in young children: (1) The frequency with which both the endo- and pericardium are involved; (2) the great tendency to acute dilatation; (3) the liability of these attacks to be complicated by pneumonia. The cardiac muscle, like the voluntary muscles, in young children, has not the resistance which it attains later. For these patients, rest as nearly absolute as possible is necessary, even for two or three months after acute symptoms.

Diphtheria and Serum Therapy, with Especial Reference to Experience in Cuba.—Joaquin L. Dueñas asserts that, in his own personal experience, he has not lost any patient from pharyngeal or laryngeal diphtheria since his employment of antitoxin.

A Case of Hydrocele of the Cord following an Operation for Strangulated Inguinal Hernia.—Burr Burton Mosher reports this case of hydrocele which was immense, and which, with the exception of the reducible protrusion, was wholly within the abdomen.

Peliosis Rheumatica in a Lymphatic Child.—J. Park West reports a case of that rather unusual disease described by Schönlein in 1829 as peliosis rheumatica. No satisfactory cause could be found.

Scorbutic Membranous Colitis.—J. Henry Fruitnight describes this case as the only instance of scurvy accompanied by the expulsion of a pseudo-membrane with which he is acquainted.

Infantile Scurvy—Mild Type.—Francis Huber reports several cases of infantile scurvy, all of the patients belonging to the better classes and all being rachitic.

Strangulation of the Fœtus in Utero by the Umbilical Cord.—Joseph W. Irwin reports this unusual case, due, probably, to the mother falling from a street car in the seventh month.

The Use of Gruels as Diluents of Cow's Milk.—By Henry Dwight Chapin. See MEDICAL RECORD, vol. lvi., p. 181.

A Case of Multiple Osteomyelitis in an Infant.—T. M. Rotch presents this case as one of pathological rather than of clinical interest.

Pediatrics, January 1, 1900.

Complications of Diphtheria.—J. A. Abt does not regard septic diphtheria as, strictly speaking, a complication of the disease, but believes with Huebner that it would be more appropriate to call these cases diphtheria gravissima or maligna, since pyogenic cocci may be absent and nearly pure cultures of diphtheria bacilli are obtained. Baginsky says that in nearly every case in which antitoxin is administered early sepsis rarely, if ever, develops. A case is cited to show that such violent toxins may be produced that it is impossible to neutralize them with the ordinary dosage of antitoxin. Heart complications may occur in the mild as in the severe forms. Paralysis may be early or late. The most feared cardiac complications occur after the local disease has disappeared. There are characteristic symptoms which should warn us: exceedingly rapid or slow pulse during convalescence, but, more important, disturbance of normal rhythm. The characteristic irregularity shows an intermission of one or two beats, or it may become double. Antitoxin can have no influence on a heart already damaged by diphtheria poison, but it is believed that the antitoxin partially or completely neutralizes the poison if given sufficiently early. It is observed that since the use of antitoxin became general severe nephritis is becoming less frequent.

Double Paralytic Varus from Peripheral Neuritis.—Henry Ling Taylor says the commonest cause of acquired clubfoot is poliomyelitis. Among the rarer causes of acquired varus or equino-varus is peripheral neuritis. The case of a girl of thirteen years is given. The neuritis is distinguishable by its sudden onset with pain, absence of fibrillar tremor and degenerative reaction, non-progressive character, and tenderness of the nerve trunks.

A Case of Interstitial Emphysema.—Max Girsdarsky records with illustrations a boy's history. After asthma, and bronchitis with emphysema of the lungs, there were sudden choking, thickening about the neck, and tumor formation, giving crepitation, and a fremitus-like sensation to the fingers. Improvement began on the sixth day. In two weeks the interstitial emphysema had disappeared.

Annals of Gynecology and Pediatry, December, 1899.

The Neuroses of the Menopause Caused by Intestinal Fermentation.—Charles J. Aldrich says that, without regard to sex, the physiology of life is marked by distinct epochs: Dentition; pubescence; and the climacteric of age. The first two are developmental, the last the epoch of degeneration and decay. To woman nature has added another, the menopause. This is a physiological process, and not a process of decay. At this time the spleen becomes smaller; the lymphatic glands waste; Peyer's patches smooth down, and lose their peculiar structure; the intestinal villi shrink and become less vascular; the muscular coats of the intestines atrophy, and lessened peristalsis ensues. The power of propelling the mixed products of indigestion and fermentation is lessened, and innumerable micro-organisms flourish and excite fermentation and elaboration of toxic alkaloids. Consequently constipation, anorexia, eructations, flushes, vertigo, headaches, and insomnia follow. Cathartics, nux vomica, and hot-water enemas will clear the tract. Massage, electricity, diet, and intestinal tonics will aid in keeping it clear.

Surgery in its Relations to the Female Pelvic Organs.—John B. Wheeler observes that in operative cases the best prospect of a complete and speedy restoration to health is afforded by a radical operation. In the case of a young woman, with most of her child-bearing life before her, it may be justifiable to offer the less reliable aid of a partial operation, in order to give her every chance to preserve the function of reproduction. In the case of a woman approaching the menopause (and *a fortiori* if she has passed it), there is no valid reason for refusing her a radical operation.

Report of a Case of Puerperal Sepsis and what It Teaches.—Charles H. Glidden says that, taking into consideration the frequent inconveniences to which the obstetrician is subject, time is well spent in considering the management of puerperal sepsis from the curative as well as the preventive standpoint.

A Case of Cystitis of Long Standing, Complicated by Chronic Malaria, Together with Sluggish Liver and Habitual Constipation.—J. W. Walker, in treating this case of cystitis, used quinine and thialion besides, and a prostatic catheter of block tin.

A Clinical Study of the Lymphatic Glands in One Hundred Cases of Scarlet Fever.—Jay F. Schamberg has carefully tabulated the results of his work on this subject, which was carried on at the Municipal Hospital for Infectious Diseases, of Philadelphia.

Puerile Indigestion.—F. C. Morgan states that ignorance and carelessness of nurse or mother are primary causes of puerile indigestion. Four facts govern the matter: Quality of food, quantity of food, frequency of administration, method of preparation.

Sudden Increase of Intra-Abdominal Pressure a Possible Danger in the Operation for the Cure of Old, Very Large, Retained Hernia.—By Henry O. Marcy. See MEDICAL RECORD, vol. lvi., p. 641.

Eclampsia.—F. L. Brigham, in reporting several cases of eclampsia, asserts that, in his opinion, veratrum viride will successfully supplant the use of the lancet in this affection.

Some Practical Experience in Asepsis and Antisepsis in Obstetrics.—By Douglas Ayres. See MEDICAL RECORD, vol. lvi., p. 636.

Intestinal Obstruction from Biliary Calculi.—By J. Wesley Bovée. See MEDICAL RECORD, vol. lvi., p. 569.

Typhoid Ostitis.—Charles F. Painter reports two cases of ostitis due to typhoid, one situated in the hip joint, and the other in the spine.

Indigestion in Infants and Children.—By James H. Taylor. See MEDICAL RECORD, vol. lvi., p. 602.

The Therapeutic Gazette, December, 1899.

The Prevention and Treatment of Puerperal Eclampsia.—Edward P. Davis says the convulsions may be readily controlled by chloroform, large doses of morphine, veratrum viride, or nitrite of amyl. Recent observers estimate that in women subjected to no care during pregnancy one in eighty-five has eclampsia. The mortality varies from fifteen to twenty-five per cent. Serum albumin is important only when in large amount and appearing with kidney débris. As a preventive measure the patient's excretion should be stimulated. An appropriate diet composed largely of milk, bread and butter, green vegetables, and fruit, with an abundance of pure and soft water, is the first prerequisite; a warm tub bath at night and a cool sponge in the morning should be taken. Thin wool or silk and wool should cover the entire surface. Fresh air and gentle exercise are necessary. Alcohol should not be allowed. The craving for tea or coffee may usually be appeased by the use of very hot water, effervescent drinks, and occasionally, for a short time, small doses of nux vomica or strychnine.

The Treatment of Eclampsia.—James Clifton Edgar takes up first the preventive, then the curative treatment, under which latter he discusses a method to control the convulsions. Among other things he advises that the uterus be emptied under deep anæsthesia by some method that is rapid and that will cause as little injury to the woman as possible. He then goes on to consider elimination of the poison or poisons which we presume cause the convulsions. A protest is entered against the careless use of the term "accouchement forcé," and to the easy confidence with which it has been recommended as the best if not the only means of controlling eclamptic seizures, without attaching sufficient importance to the condition of the cervical barrier.

The Treatment of Eclampsia.—Richard C. Norris thinks prevention the most efficient treatment. Neuralgia of obstinate character, irritable temper, excessive vomiting, marked salivation, coated tongue, hebetude, and signs of inactive liver are indications for treatment. The formation of toxins is to be prevented by diet, while the liver must be aided to destroy them and the excretory organs to eliminate them. The colon should be flushed daily with at least two gallons of salt solution. Chloroform is preferable to morphine in controlling convulsions.

The Treatment of Puerperal Eclampsia.—A. F. A. King assumes the convulsions to be of uræmic nature, and prescribes hydragogue cathartics and hot baths or wet packs, dry or wet cuppings, one application of mustard plaster, then hot poultices of flaxseed and digitalis leaves. Absolute quiet is necessary. He places a gag between the teeth, and pulls forward the tongue after the convulsion to prevent its falling back and endangering respiration, which are practical points of importance.

The Treatment of Puerperal Eclampsia.—Edward Reynolds is a strong believer in the efficacy of diuresis, catharsis, and diaphoresis, rest in bed, milk diet, and mild sedatives, such as the bromides. Immediate delivery under ether is advocated for all cases in which one convulsion has occurred. He occasionally uses a single injection of one-sixth grain of pilocarpine. He prefers chloral to morphine.

A Case of Fibroma Molluscum and Dermatolysis.—H. Clarence and F. G. H. Edwards report the case of a man who had two heavy pendulous folds of skin, one on the face and the other on the chest and shoulder, and also numerous small tumors scattered over the trunk and arms. One of the tumors, which was removed, weighed 1,530 gm. (about three and one-third pounds). The authors regard dermatolysis and fibroma molluscum as the same affection at different stages, and propose the term "fibroma molluscum multiforme."—*Journal of Tropical Medicine, December, 1899.*

Therapeutic Hints.

Arsenic Antidote.—

℞ Tinct. ferri chlor.,
Sodii (vel potass.) bicarb āā ℥ i.
Aquæ (warm) ℥ viij.
M. S. Ad libitum.

Styptic Collodion.—

℞ Acidi benzoici ʒ iij.
Tannini ʒ v.
Phenol ℥ i.
Collodion ℥ xiij.

Iodoform Gauze.—

℞ Iodoform ʒ xiiss.
Elemi resin ʒ i. gr. xv.
Ster. vaseline oil ʒ iiss.
Rectified benzene ℥ xvi.
Ether ℥ xxij.

Add the resin to the mixed liquids; filter and dissolve the iodoform by agitation.

Atropin. sulph gr. $\frac{1}{30}$
Ergotin gr. xx.
Alcohol q. s. (to dissolve)
Aquæ ʒ ij.
M. S. Eight to ten drops in small amount of water, repeated at intervals.

—Robin.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 4, 1900.

William H. Thomson, M.D., President.

Treasurer's Report.—This showed the Academy to be now free from debt.

Pathology of Migraine.—Dr. Coleman W. Cutler presented a paper on this topic. He said that migraine was a periodical or paroxysmal neurosis making its appearance in childhood or early adult life, and characterized by headache, often preceded by an aura, and associated with vomiting. The visual aura was the most common, and usually consisted of peculiar color perceptions with perhaps spasm of the muscles of accommodation. Olfactory or taste perceptions, as a part of the aura, were decidedly rare. In the great majority of cases migraine was transmitted in the family as such, but coincident with it other minor neuroses might occur. It was probable that epilepsy might be accompanied by phenomena simulating migraine, or alternating with it. Symptomatic migraine might be an early sign of tabes. The tension of the eye should be tested in all cases of ocular pain, especially if associated with scintillations of light. The tendency of migraine was to begin in youth and end in middle age. Heredity was a predisposing cause in from ninety to ninety-five per cent. of all cases. The exciting causes were exceedingly numerous. A certain number of cases seemed to resist all efforts at treatment. The relation of latent gout to migraine was still an open question. In at least fifty per cent. of the cases reaching the oculist the attacks became less frequent and often ceased entirely after a proper course of treatment.

Significance of Migraine in Graves' Disease.—Dr. William H. Thomson read this paper. He said that there was probably no other disease so decidedly hereditary as migraine, and it had therefore been classed as a neurosis. His own view was, that it was more probably the result of an intermittent toxæmia. No slight significance should be attached to the fact that whole classes of individuals were free from migraine, and other whole classes were victims of this affection. The persons forming the class subject to migraine were those leading indoor and more or less sedentary lives. In this respect migraine was very different from epilepsy, for in the latter disease the individuals affected were found in both indoor and outdoor workers. Active bodily labor wholly prevented stasis of the circulation, whereas sedentary life favored stasis. In the former, good digestion was the rule; in the latter it was the exception. He would call attention to the fact that Graves' disease might often exist, and severely too, without any exophthalmos. In his experience the malady had ended fatally in a larger percentage of cases in which there was no exophthalmos. He had detailed notes of sixty-five cases of Graves' disease seen in private practice. Of this number, thirty-two were without and thirty-three with exophthalmic goitre. The total symptomatology of Graves' disease, with this one exception, was so characteristic that there was no difficulty in making the diagnosis. In all of the sixty-five patients there had been persistent tachycardia, and this had been as marked in those without as those with exophthalmic goitre. Tachycardia he looked upon as an essential symptom of this affection, and it was particularly important because without it one would be liable to mistake the condition for neurasthenia, hysteria, or dyspepsia. Tachycardia was usually one of the earliest symptoms to appear and one of the last to go away. Another very characteristic symptom was the sense of general nervousness very commonly described by the patient as an unreasonable fright. Another frequent symptom was muscular tremor, worse in the morning, and often passing off altogether by evening. Of the sixty-five patients only sixty stated that all of their symptoms were worse in the morning. Tremor of the eyes was present in every one of the cases in which there was no exophthalmos. These patients often complained of pains in various parts, chiefly in the legs, associated with tenderness. A peculiar hyperæsthesia of the external ear had been noted in a considerable proportion of both classes of cases. Severe vertigo had been present in about one-fifth of the cases. A most striking parallel between the two classes was to be found in derangements of the digestive apparatus. In some of the cases there had been a persistent nausea occurring independently of the taking of food. Diarrhœa had been a leading symptom in sixteen of the thirty-two cases in which there had been no exophthalmic goitre, and had been characterized as painless. It was said to be worse in the morning. It was quite uniformly asserted that the other symptoms were aggravated with the occurrence of diarrhœa, but the general course of the disease had been about the same in the cases showing diarrhœa as those charaterized by constipation. Persistent vomiting was a serious symptom in many cases of both classes. One very severe case was that of the wife of a physician who had assiduously watched her for two years, but who had never suspected the existence of Graves' disease because of the absence of exophthalmic goitre. This should impress upon us the evil of naming diseases after one symptom. He believed the primary cause of Graves' disease was an auto-infection from the alimentary canal, and that it was associated with a peculiar inability properly to digest nitrogenous food. It was conceivable that the presence of such poisons in the blood in excess might overstimulate the thyroid gland, and might occasionally lead to atrophy of the gland and to myxœdema. The speaker said that only since 1896 had his attention been specially directed to the frequency of migraine in connection with Graves' disease. He had seen but one case in which migraine and epilepsy had been found in the same individual. This person had had epilepsy from the age of seven until coming under observation at the age of eighteen years. The epilepsy had been made to disappear entirely, but some years later she had developed an exophthalmic goitre, and still later migraine had appeared. The occurrence of migraine as a family complaint in Graves' disease had been noted in sixty-five of the cases.

Dr. C. L. Dana said that at the present time most neurologists looked upon migraine as an hereditary constitutional neurosis, paroxysmal in character, and occurring in the same periodical way as epilepsy and certain other neuroses. It was considered to be a discharging neurosis affecting more highly evolved psychical nerve centres than were affected in epilepsy. Such centres one would naturally expect to find more highly developed in brain-workers than in ordinary laborers. While the disease was incurable, much relief could be afforded by lessening the irritation and the exhaustion of the centres. By relieving eye-strain, removing sources of intestinal irritation, and securing more outdoor life, much could be accomplished. Next in importance to treatment directed to the mode of life was that having for its object the improvement of the digestion. He was not in a position at present to discuss the interesting clinical studies presented in the last paper regarding the relation of migraine to Graves' disease. One of the most interesting features of the pathology of migraine was that it certainly had neurotic equivalents. He had seen cases of migraine with the headache at intervals for years, and then this pain would be replaced by attacks of periodical ptosis. He had not noted that migraine and epilepsy occurred very frequently in the same family, or were very closely allied in their pathology.

Dr. B. Sachs said that the occurrence of migraine and epilepsy in the same individual was undoubtedly rare; he could not recall more than two such cases, and in these the migraine had followed the cessation of the epilepsy. That migraine was the result of toxæmia seemed to him purely speculative. Toxæmias might act as exciting causes, but nothing more. Reference was made to the case of a young man suffering from epilepsy who had developed acute pulmonary tuberculosis, and on the occurrence of this intercurrent disease he had exhibited no further epileptic seizures. This relation of epilepsy to acute infectious disease was interesting, and to him novel. It seemed to him rather injudicious to diagnosticate as Graves' disease every case exhibiting tachycardia.

Dr. Thomson, in closing the discussion, said that he would not make the diagnosis of Graves' disease on persistent tachycardia alone, but he would be willing to make the diagnosis, even in the absence of exophthalmic goitre, if along with the tachycardia there were muscular tremors, paræsthesiæ of one kind or another, persistent constipation or diarrhœa—in a word, clear evidence of a serious constitutional disorder. The object of his paper was to call attention to the frequency of this malady without any associated exophthalmic goitre.

SECTION ON GENERAL MEDICINE.

Stated Meeting, December 19, 1899.

Louis Faugères Bishop, M.D., Chairman.

The Relative Intensity of the Second Sounds at the Base of the Heart: A Study of One Thousand Cases.—This paper, by Sarah R. Creighton, M.D., was read by Lewis A. Connor, M.D. (See page 45.)

Dr. Emily Lewi said that the explanation of the phenomena was perfectly satisfactory to her, and that there were a number of anatomical factors in the position of the child's heart and the adolescent's heart, as compared to the adult heart, that would account for the clearness of the sound. The heart of the infant, of the child, and of the adolescent lay more vertically in the thorax than it did later in life; incisions made into the frozen subject showed this. If a transverse incision was made through a child's heart at the level of the aortic valve it would pass through the thick right ventricle. Another anatomical peculiarity of the child's heart was that the left pleura hardly went to the left edge of the sternum, whereas the right pleura went to the left margin of the sternum. These were additional factors in making increased intensity of the second pulmonary sound as heard in the child. The speaker had noticed for some years that anæmia or chlorosis, in girls from fifteen to twenty years of age, caused an accentuation of the second pulmonary sound; whereas in girls who had no marked chlorosis—hæmoglobin seventy or eighty per cent.—this sound was merely a click, probably due to the condition of the blood. The speaker believed that one should have some standard for comparison, for it would not appear that the same heart sound could be heard in a girl of twenty years as would be heard in a man of sixty; nor should we expect to have the same quality of sound at the base as at the apex.

Dr. James K. Crook said that, in an experience covering many years in both teaching and in examining many patients, he could bear testimony to the fact that the aortic first sound was more intense than the pulmonary second sound in the adult. The pulmonary second sound was more responsive to disturbances of the circulation. In the presence of excitement the pulmonary second sound was more quickly responsive than the aortic second sound. What conditions led to variations in the pulmonary second sound? Mitral stenosis caused a marked increase of the aortic second sound. The blood was dammed back on the lungs through the pulmonary capillaries, back to the pulmonary artery, and in consequence there were increased pressure and increased tension of the pulmonary artery, and greater recoil against the valves. This was marked in emphysema and in pneumonia, *i.e.*, the acute lobar form. In this disease the study of the second sound was a very important point; so long as the power held out the pulmonary second sound was accentuated; but when it began to fail it was always an ill omen. The application of a tourniquet to the limb influenced pressure in the aorta, and there followed a little accentuation of the second sound. This was increased in conditions of general arterial tension, as was found in Bright's disease, in chilling of the surface after exposure to cold, and in epilepsy. Balfour claimed that whenever there was accentuation of the second sound there was hypertrophy of the left ventricle.

Dr. Lewis A. Connor said the fact that not all the cases were normal cases, some patients having anæmia, others pulmonary tuberculosis, etc., might interfere with the accuracy of the records; but many of those examined were not at all ill. The doctors, the nurses, the parents who accompanied children, were examined, and as great care was taken the probabilities were that the records were not far from right. Most text-books made a mistake in not distinguishing between the sounds heard in the adult and the sounds heard in children. From the age of thirty years on there was marked accentuation of the second sound; this accentuation was more marked and constant with each decade. Dr. Creighton did not think her explanations adequate; they were only suggestions. Regarding the taking of the aortic second sound as the standard, that could be done only when we were sure that the individual was perfectly normal.

A Case of Bilobar Pneumonia; Purulent Pericarditis; Pericardotomy; Recovery.—Dr. Morris Manges presented the patient, whose history briefly was as follows: The boy, aged fifteen years, was admitted to the wards of the Mt. Sinai Hospital on July 6th last. His illness began two days previous with fever, chill, etc., and he presented a pneumonic process at the right base and left apex. He was then suffering from a bilobar pneumonia. His condition remained the same until July 9th, when there was flatness at the right base; he was aspirated, in the expectation of finding fluid; but none was found. Two days later he became worse, and a trilobar pneumonia was found, the left lobe being involved. In spite of all his general condition remained relatively good. Respiration was 92, with pulse and other things corresponding. Resolution began on July 13th, and his condition improved rapidly. On the following day there was found a to-and-fro friction murmur at the base. The pulse was irregular and paradoxical. Resolution continued until his general condition improved. The pericardial area soon became smaller, and the temptation to tap the pericardium was resisted. The boy's condition continued to improve until August 6th, when a friction murmur was readily obtained over the base of the heart. The heart became more rapid, and the case looked like a septic one. On August 13th things suddenly changed; there was an increase in the dyspnœa and vomiting occurred; the pulse became irregular, and gradually the dulness increased so that the area became advanced one-half an inch outside the left nipple line. It was decided that the pericardium then should be emptied, and eighteen and one-half ounces of purulent fluid was taken away; the microscope showed this to contain pure cultures of the pneumococcus of Fränkel. The relief was transitory. Next the pericardial sac was opened, and forty fluidounces removed. The patient continued to improve, although there was a consolidation of the left lobe posteriorly. On September 4th the boy was out of bed and was then discharged. The patient was then shown to have had a typical adherent pericarditis; the cardiac area was normal, and there was no murmur. His general condition was good, and the boy was now following his occupation of a district telegraph messenger.

In Dr. Meyer's analysis of five hundred cases of lobar pneumonia, fifty-eight cases were bilateral, of which only twenty-seven per cent. resulted fatally. Pericarditis was a complication in eleven cases; in forty-one cases there was an endocarditis; of these there was a mortality of forty-five per cent. Regarding the patient shown, he said the pericarditis *per se* did not influence his recovery in any way. It was not until one month had passed that the pericarditis developed. The septic condition being of a moderate type was explained probably by its not being due to the streptococcus or the staphylococcus, but to the pneumococcic infection. Although pericardial effusion occurred in pneumonia it did not call for immediate interference. The pneumococcus was the cause of many cases of pericarditis. Regarding pyo-pericarditis, it might occur in pneumonia, osteomyelitis, traumatism, etc. As a rule the attention was called to the occurrence of pericarditis by a to-and-fro murmur; one should bear in mind that this might last but a few hours, and so might often be overlooked; pericarditis with effusion was often present without giving rise to symptoms, even when the effusion was very large. Pyo-pericarditis was not rare. There had been six cases in the Mt. Sinai Hospital, three of which resulted in recovery, and three were fatal; three patients died after aspiration. Aspiration did good in all but one case. In one case one ounce was drawn off; the patient was cured. In the second case two ounces of blood and serum were removed, but the patient died. In another case two ounces was withdrawn; the patient recovered. The fourth case was the one cited; eighteen and one-half ounces was drawn off, and the patient recovered. On the other hand, in some cases aspirated it would have been better to have left them alone. A small needle should be inserted to get the serum for diagnosis. If simply serum was found and the symptoms were not urgent, the case should be let alone; if pus was found, the patient should be handed over to the surgeon. In the patient presented, eighteen and one-half ounces of pus was removed the first day, and forty ounces the next, making fifty-eight and one-half ounces removed, which was an exceedingly large quantity to be taken from a boy of his size. There must be some good indication for aspirating. Skoda said that there were two good rules for entering the pericardial sac: (1) when the sac was distended with a large exudate which showed no tendency to absorb, and the patient was running down; (2) a vital indication was intense dyspnœa.

Dr. Howard Lilienthal's remarks were read by Dr. Manges. On account of the intense dyspnœa, and the boy's bad condition, it was decided to use eucaine as a local anæsthetic. During the operation the boy's attention was drawn away from the work by talking to him. He was not told that an incision was to be made; he thought that he was to be aspirated again. He felt no pain at all. A trap-door was made as suggested by Roberts. It was a triangular one, beginning one-half inch from the sternal border. The hemorrhage was insignificant. A stitch was used to make the wound patent. The pericardium was thick and so rigid that the skin was drawn in instead of the pericardium being drawn out. Irrigation was made with a soft-rubber tube. Six weeks after the operation the patient was discharged. Pyo-pericarditis was a surgical disease, and harm could result only from delay in treating it surgically. Tapping had invariably failed in all cases treated. Eucaine seemed to the author to be the best anæsthetic in these cases. There was danger of infecting the pleural cavity if special care was not taken.

Dr. Lewis A. Connor related a curious and remarkable case which occurred during his service at the Hudson Street Hospital. The man was thirty-five years of age, and came into the hospital in a condition hardly showing a case of pericarditis. The patient went on from bad to worse, and finally his condition became so grave and his state so critical that he was aspirated, and thirty ounces of fluid was removed. The patient was then turned over to Dr. Stimson. He was placed on the operating-table, and a four-per-cent. cocaine solution was used as an anæsthetic. A rib was exsected, and an enormous quantity of pus was discharged, probably sixty or seventy ounces. A slight nick in the left pleura was made, and the operators were surprised to find that the left pleura extended so far to the right. The patient lived for some days afterward, but died of sepsis, which could not be explained by the condition in the pericardium, which was thoroughly and completely drained. There were some obscure and indistinct signs over the chest. The autopsy showed that the pericardium had been doing well, but there was a sacculated empyema of the left pleural cavity which it was difficult to recognize clinically. If the pleura had not been infected the speaker believed the man might have recovered.

Premature Burials.—Dr. H. L. Garrigues read a brief paper on this subject. He said that physicians differed much in their views as to whether burials of living persons were frequent or not, some declaring that they never occurred, and one, who had made a special study of the question, saying that one person out of every two hundred was buried alive. He did not believe that premature burials were very rare—first, because, though graves were so rarely opened, yet it was found in a number of cases that the inmate of the grave had revived in the coffin; second, because there were so many narrow escapes from being buried alive; third, because of the unreliability of the so-called signs of death, with the sole exception of unquestionable putrefaction of vital organs; fourth, because of the absence of proper laws to protect the apparently dead against live burial; fifth, because of the carelessness with which death certificates were signed by physicians. The speaker favored waiting mortuaries, where bodies should be kept under proper supervision till decomposition had begun. He concluded his paper by stating that only authorized practitioners of medicine should decide whether a person was dead or not; that blanks for certificates of death should contain questions in regard to the chief signs of death, and the physician signing the certificate should answer each question with "yes" or "no," besides declaring that he personally had examined the body; that it should be made a crime to do anything to the supposed dead that would cause pain or injury to a living person, before the certificate was signed. As long as nothing of the kind was done, nobody had any guarantee that he would not be buried alive, thrown into a glowing furnace, or be killed by the performers of autopsies, the undertakers with their ice-boxes, or the embalmers with their solutions of arsenic.

Demonstration and Description of Apparatus to Prevent Premature Burial.—M. Emile Camis, of Paris, demonstrated the life-saving apparatus, "le karnice," which was composed of a tube four inches in diameter, resting on the casket, and connected at the other end to a rectangular metallic box containing signals. The metallic box alone was visible above the grave; the other parts were buried in the ground. A metal rod passed through the axis of this tube, its lower end going into the casket and being placed in communication with the signals in the metallic box at its upper end. The part of the rod entering the casket terminated in a ball which was placed one and three-fourths to two inches from the sternum of the interred person. Should a movement of the body in the casket occur the ball was displaced; by the aid of simple mechanism a general simultaneous action took place; the box was opened, and the signals, bell, flag, shining ball were put in motion or were displayed; the sound of the bell was sufficiently sonorous to attract the attention of the cemetery watchman. Also the buried person received air and light, even at night, and his voice was carried through the tube and heard over a large radius.

Election of Officers.—The following officers were elected for the ensuing year: *Chairman*, John H. Huddleston, M.D.; *Secretary*, E. Franklin Smith, M.D.

SECTION ON OBSTETRICS AND GYNÆCOLOGY.

Stated Meeting, December 28, 1899.

Brooks H. Wells, M.D., Chairman.

Imperforate Uterus with a Large Hæmatoma of the Ovary.—Dr. H. J. Garrigues presented a specimen taken from a young girl, twenty years of age, who had never menstruated. She had suffered from epileptic seizures coming not only at the time of the menstrual molimina, but in the intervals. Vaginal examination had revealed a normal vulva and a vagina two inches deep. Above this was a large, round mass, one portion of which was much harder than the rest. On October 25, 1899, he had performed laparotomy. This had revealed a uterus about the normal size and shape, though a little thicker antero-posteriorly than normal. The right ovary was slightly enlarged, and showed a fresh corpus luteum filled with blood. The right tube was normal. The left tube was bound to a cyst nearly filling the pelvis, and adherent to the intestine. He had removed the uterus, and had then extirpated the cyst, which proved to be a hæmatoma containing ten ounces of chocolate-colored bloody fluid. Seventeen days after the operation three pints of old blood, mixed with pus, had been evacuated through the vagina. A sound had passed through an opening in the upper vagina in the direction of the right iliac fossa. The opening had been dilated, and the cavity drained. The patient did not now suffer from the menstrual molimina, but she had had several epileptic seizures during her stay in the hospital. The tubes were found to be lined with normal mucous membrane. There was no evidence of a canal in the uterus. The fact that the uterus was of nearly normal size and shape made the case almost unique. The hæmatoma was an evidence of vicarious menstruation internally which, according to the history, had been going on for about four years.

Dr. P. A. Harris asked what had intervened between the cervix and the depression representing the vagina.

Dr. Garrigues said that he had seen one other solid uterus, but it had not presented the usual shape of a normal uterus. In reply to the question of Dr. Harris he said there had been about half an inch of soft tissue intervening. In two other cases he had succeeded in making a connection between a stenosed vagina and the uterus, and such a procedure would have been indicated here had he not been informed that a competent gynæcologist had already attempted something of the kind. In view of the epileptic seizures and the diminished intelligence of the girl it had seemed to him that laparotomy was justifiable.

A Combined Endoscope and Cystoscope.—Dr. A. H. Goelet said that he had been interested in endoscopy of the uterus for the past two years, but had been unable to accomplish what he had desired because he had been working with reflected light. At present he was using direct light with much better results. An instrument constructed on this principle was exhibited, and its action demonstrated. For more minute inspection, when that was desirable, a magnifying glass was attached. The source of illumination was a tiny electric light. He had found the instrument principally of value in the determination of the necessity for curetting. By such inspection one could decide whether there was an active endometritis present or only a hyperæmia. One could also determine by such examination whether the endometritis was confined to the cervix or implicated the body, and could inspect the orifices of the Fallopian tubes. The complete apparatus cost $30; the lamp could be renewed at a cost of $2, and was guaranteed to last at least thirty consecutive hours. The four dry cells could be replaced at a cost of $1. He had found the magnifying glass a great aid in passing the ureteral catheter.

Dr. Garrigues remarked that it might be possible to introduce the smaller size of this instrument without anæsthesia, but the degree of dilatation required for the other two sizes would certainly demand the employment of an anæsthetic. He was of the opinion that such inspection of the interior of the uterus would prove a valuable aid to the clinician.

A Case of Ectopic Gestation with Unusual Symptoms.—Dr. Ralph Waldo reported the following case: A married woman, twenty-nine years of age, had been admitted to the Lebanon Hospital with the history of having weaned her last child four weeks previously. She had had an excessive bloody flow, which she had taken to be her menses. As it had been profuse she had been curetted, but with no control of the hemorrhage. On admission, she had stated that she had had only very slight abdominal pains. She was very much exsanguinated, and was flowing so freely that a tampon was required. Examination had revealed a mass the size of a hen's egg situated behind the uterus. On November 3d she had been etherized and the uterus curetted, with negative result. The diagnosis of tubal pregnancy had been made in spite of the fact that the tumor was not sensitive, and that there had been severe and persistent uterine hemorrhage. The tumor had been freely movable, and had involved the upper half of the right tube. After an interval of twenty-four hours the bleeding had returned, and on November 27th it had been so profuse as to necessitate tamponade of the uterus to save the patient's life. The following day laparotomy had been done. This had revealed an ectopic gestation in the outer half of the right tube, and a clot protruding from its fimbriated extremity. The tumor had not ruptured. There was a large quantity of blood in the abdominal cavity. The fœtus had not been found, although other products of conception had been present in the tube. The left ovary was three inches in diameter, and was composed of several well-defined cysts. This ovary and its tube had been removed, and the patient had made an uninterrupted recovery. The case was reported because of the absence of tenderness and the profuseness of the hemorrhage.

Dr. H. J. Boldt also presented a specimen of ectopic gestation. It had been taken from a woman who had been seized nine days ago with severe pain in the lower part of the abdomen. From her extreme pallor, the excessive tenderness of the abdomen, and the sensitiveness and fulness in the vaginal cul-de-sac, he had suspected ectopic gestation. The woman also had a complete procidentia of the uterus. She had been kept in the hospital for a few days for observation, but as she had not improved he had opened the cul-de-sac two days ago, and at once a quantity of blood had gushed out. He had then removed the uterus, and had discovered that the impregnated tube had ruptured near its abdominal extremity. The last menstruation was said to have been on time, but he had just learned that the last period had been of only two days' duration, whereas the preceding one had lasted nine days. With this exception the history had been absolutely negative as regards pregnancy.

Intussusception Mistaken for Ectopic Gestation.—Dr. Boldt also presented a specimen from a case which had been supposed to be one of extra-uterine pregnancy. It had been removed from a woman who had been taken ill with severe vomiting She was supposed at that time to be pregnant about six weeks. Albuminuria was present. For the next two or three days there had been a slight rise of temperature, and an increasing and diffused abdominal tenderness. She had stated that she had not menstruated for six weeks, and had had some abdominal pain, during which time there had been a slight bloody discharge —a "spotting." When seen by the speaker the pulse had been small and rapid, and the temperature a little over 100° F. The greatest tenderness had been in the left iliac fossa. On vaginal examination the uterus had been found soft and rather large, and to the left was a large doughy mass filling the cul-de-sac. A few hours later he had opened the abdomen, and had been rather surprised not to find any blood. A peritonitis was present. A portion of the intestine was found in the pelvis, and this was gangrenous for a considerable length. On opening the bowel he had found an intussusception, due to the presence of a polypus which measured seven and one-half by eleven and one-fourth inches. The case was of interest because he had at first made a provisional diagnosis of intussusception, but had changed it after having made a vaginal examination. On looking over the literature of the subject he had found one case reported by Otto Kustner in which menstruation had suddenly ceased in a woman having a retroflexed and adherent uterus. After nine weeks the woman had consulted Kustner, and he had found a sensitive tumor to the left of the uterus. About this time there had been a slight bloody flow for a few days. On auscultation of the abdomen a sound had been heard which had been taken for the placental souffle. Having skipped her third period she had been examined under anæsthesia, and then it had been discovered that the above-mentioned tumor had increased to the size of a gestation at the third month. A diagnosis of ectopic gestation had then been made, and laparotomy had been performed. The operation had revealed, not ectopic gestation, but a sarcoma of the ovary with numerous hemorrhagic infarctions. This woman had previously never missed her menstrual periods.

Dr. P. A. Harris remarked that in two or three cases of ectopic gestation coming under his care there had been an excessive bloody flow, although in addition there had been pain and tenderness.

Dr. Waldo called attention to the fact that in his case the hemorrhage had been so excessive that tamponade of the uterus had been demanded on two occasions as a life-saving measure.

Soft Myoma in a Young Girl; Wrong Diagnosis.—Dr. H. J. Boldt reported the following unusual case occurring in a virgin aged eighteen years. Menstruation had been established only about two years. On examination he had found a freely movable tumor extending nearly up to the umbilicus. Examination under an anæsthetic had failed to show the presence of ovaries. The tumor had presented marked fluctuation. A diagnosis of ovarian cystoma had been made, but on introducing a trocar nothing had been removed. The abdomen had then been opened, and this had revealed an exceedingly soft myoma. The fact that it had occurred in a patient so young was of peculiar interest.

Fibroma of the Ovary.—Dr. A. Brothers said that he had seen at his clinic, last summer, a woman aged forty-seven years, the mother of seven children. She had been well until six years ago, when she had noticed a swelling in the abdomen. This had steadily increased in size. A hard tumor, apparently a fibroid, could be easily mapped out. Seven weeks later she had been admitted to the Post-Graduate Hospital with a pulse of 136, a temperature of 101.8° F., and excessive tenderness of the abdomen. A few days later laparotomy had been done, revealing a tumor separate from the uterus. A considerable quantity of pus had escaped during the effort to remove the tumor. The latter had proved to be a fibroma of the ovary. On account of the suppurative condition present, through drainage had been established by way of the vagina. After the operation the temperature had risen to 104° F. and the pulse to 144. Two days later the dressings had been found soiled with fæces. A few days after this the urine had shown evidences of nephritis, and the patient had become delirious. Suspecting iodoform poisoning, as well as nephritis, the parts were flushed and all iodoform was removed. She had improved steadily after this, but a secondary operation had been required to secure closure of the wound. The pathologist, Dr. Henry T. Brooks, said that he could find no trace of ovarian structure, yet he inclined to the diagnosis of fibroma of the ovary.

Dr. Garrigues said that a number of years ago two large tumors had been brought to him for microscopical examination. They were ovaries, yet there had been no trace of ovarian tissue remaining, the masses having been entirely converted into fibrous tissue.

Dr. Boldt said that a few years ago Dr. F. Ferguson had examined for him a fibroma of the ovary. He had seen one other case in which the appearance had been that of a fibroma, but no microscopical examination had been made. With regard to the case just reported by Dr. Brothers, he would say that the suppuration was due either to a complicating appendicitis or to traumatism. The latter cause was not uncommon when, as in the case under discussion, several students had been allowed to make a pelvic examination.

Imperforate Hymen.—Dr. A. Ernest Gallant presented a specimen of imperforate hymen. A young woman who had been married seven weeks had presented herself because sexual intercourse was impossible. On examination he had found a crescentic hymen with a band at the upper portion, which had constituted the obstruction.

Dr. Brooks H. Wells referred to two cases which he had seen in which there had been a tiny opening through a thick and fleshy hymen.

Dr. P. A. Harris said that about twelve years ago he had operated upon a woman who had been married six years. Sexual intercourse had been impossible because of a very small opening. He had removed portions at a time, and had practised dilatation. She had been very grateful for the relief afforded, and about one year later had been delivered of a child. Subsequently she had expressed her sorrow at having submitted to the operation, because the children were coming so rapidly.

A Second Contribution to the Study of Ulcerative Lesions of the Vulva, Commonly Called Lupus or Esthiomene.—DR. GRACE PECKHAM-MURRAY read a paper with this title. She stated that the case forming the basis of this paper had been first reported upon to the Academy of Medicine in May, 1887. The patient was a woman, forty-eight years of age, who at that time had passed the menopause two years. She had had six children and one miscarriage. In 1879 she had married the second time, her second husband being a Norwegian sailor who had had syphilis. Microscopical examination of the growth about the vulva had been made by Dr. H. C. Coe, at that time the pathologist of the Woman's Hospital, and he had reported evidence only of inflammation of connective tissue. The question had arisen as to whether the ulcerative condition present was non-specific or was the result of tuberculous or syphilitic infection. Dr. Murray said that since her first paper on this subject there had been only five others published. She had succeeded in collecting from the literature only sixty cases of this affection, showing its rarity. Pozzi had given, in his text-book, one of the best descriptions of this disease. In 1889 Dr. J. Nevins Hyde had described these cases under the title "Syphiloma of the Vulva." In 1890 Dr. Robert W. Taylor had presented an article on the same subject, elaborately illustrated. He divided these cases into six classes. One class represented simple ulceration; the other five were various forms of syphilitic ulceration. Dr. Taylor had repudiated the idea of these cases being lupus. All observers agreed concerning the slowness of growth. The speaker said that she believed that the disease might be the result of prolonged irritation. She was not prepared to say that these cases were never lupus, but she believed that this form of ulceration might be tuberculous, syphilitic, or non-specific. In the case reported by her the original intention had been to remove the tissue by operation, but the patient would not consent. There had been only one microscopical examination made, but in view of the fact that a number of cases had been reported in all of which the microscopical appearances had been the same, she had not thought it necessary to have the examination repeated.

DR. J. H. EMERSON said that he had seen an almost identical case, and had had it examined by a pathologist, with like result. In that case the history had been one of alternate healing and breaking down. After a long course of antisyphilitic treatment without benefit, she had been sent to St. Luke's Hospital, and Dr. B. Farquhar Curtis had done an extensive resection, but the patient had not remained in the hospital long enough to secure proper healing.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, December 26, 1899.

GEORGE B. FOWLER, M.D., PRESIDENT.

Successful Removal of a Large Encephalocele from a Child.—DR. A. PALMER DUDLEY reported a case of hydrencephalocele which had been admitted to the Harlem Hospital on October 17, 1899, and had been operated upon by him when the child was only six days old. The child was the seventh born to its parents, and all of the previous children and all of the confinements had been normal. According to the history, the mother had suffered severely from nausea during her pregnancy, and had been in labor for two days, and had then been delivered by a midwife. On admission, the child's temperature had been 99° F., the pulse 120, and the respirations 26. The child had a microcephalic head and was poorly nourished. There was general skeletal evidence of rickets. About one inch below the posterior fontanelle was a distinct pedicle which supported a large hernial tumor. This tumor was translucent except at its neck, and the fundus of the sac was about on a level with the middle dorsal region of the spine. The anterior and posterior fontanelles were large, the sutures of the skull were separated, and all of the bones of the cranium were poorly ossified. At a point just above the external occipital protuberance was an opening through which protruded the encephalocele. The tumor gave no impulse on coughing, but was fluctuating and irreducible. The longest diameter of the tumor was nine inches, the transverse five inches, and the diameter of the opening in the occipital bone one and a half inches. There were no special constitutional symptoms, and absolutely no cerebral or localizing symptoms. On October 21st he had done a complete amputation of the hernial sac and its contents without anæsthesia of any kind. A ligature of catgut was applied around the pedicle and slowly tightened. During this process there were general contractions of the muscles of the left half of the body. Two flaps of good size were dissected up. Over two pints of a straw-colored fluid were evacuated on making an incision. The ligature at this time had slipped, and had been removed entirely. There had been but little hemorrhage in spite of this accident. The cerebral hernia had then been divided at its neck, thus completing the amputation. No vessel had required ligature. The child had seemed to suffer no pain during the operation, and had certainly made no outcry. Very little shock had followed the operation, and during the next nine days the temperature had remained at about 100° F., and the pulse between 100 and 124. Slight suppuration had occurred about the stitches, and the latter had been removed on the ninth day. On the evening of that day the temperature had fallen to 96° F., and there had been slight convulsions on the right side of the body and face. There had also been some spastic rigidity. During the next twenty-nine days the temperature had been remittent. On the fortieth day the temperature had fallen to the normal point, and had remained there since that time. The stump had healed well, but there had been no ossification about the hernial opening. The child had taken nourishment well. Ophthalmoscopical examination showed the vessels of the retina to be apparently normal. The pupils did not react to light. The speaker said that, of seventy-nine recorded cases, in fifty-three the opening had been in the occipital bone. In six instances the subject had reached adult life; the others had died in early childhood. The case reported was not a simple meningocele or a simple encepholocele, but a hydrencephalocele. He had removed 57 gm., or nearly two ounces, of brain substance at the operation. Microscopical examination showed the portion removed to be brain tissue, but the pathologist was unable to locate the part. Both child and specimen were exhibited.

DR. WILLIAM M. LESZYNSKY said that it was a question in his mind whether such an operation was justifiable save for cosmetic purposes. The very fact that 57 gm. of brain substance had been removed showed how dismal must be the outlook for this child; even if the baby should live for some time it was not likely that it would be able to see—indeed, the lack of pupillary reaction pointed strongly in that direction.

Acquired Non-Malignant Stricture of the Rectum.—DR. W. DUFF BULLARD read a paper with this title (see page 47).

Dr. Otto Kiliani said that at first one might be surprised at the statement that the majority of rectal strictures were of syphilitic origin, but those who saw many cases of rectal disease knew this to be a fact. When a stricture assumed the form of a complete ring it was not uncommon to find two or three other such rings situated a short distance apart. When the ulceration was severe and obstinate to treatment he would favor an early resort to inguinal colostomy. Proctotomy would not be sufficient in all cases; sometimes extirpation would alone meet the indications.

Dr. James P. Tuttle expressed his great surprise at the statement that syphilis was only a predisposing factor of rectal stricture. Of course, a man with syphilis might have a benign stricture of the rectum, or even a stricture in which tubercle bacilli were present, but this did not prove the stricture to be tuberculous. Tuberculosis of the rectum rarely manifested itself by such an amount of infiltration as one would expect would be necessary to cause rectal stricture. If both traumatic and non-traumatic strictures were considered, he would say that it was perfectly true that a majority of rectal strictures were non-malignant; but if only pathological strictures of the rectum were under consideration, then he would assert that fully sixty-six per cent. were due to syphilis. In a case of traumatic or simple inflammatory stricture the microscope showed an increase of fibrin and fibrous tissue with little cell increase, and no characteristic change in the blood-vessels. Before one could say positively that a stricture was syphilitic or non-syphilitic, the tissue must be subjected to careful microscopical examination. Ulceration and cellular infiltration, or fibrous cicatrization, were the essential elements in the production of rectal stricture. Pathology had certainly demonstrated the characteristic differences between syphilitic and simple inflammatory stricture. Regarding the treatment he would say that he had been deeply disappointed with the operation of posterior proctotomy because these strictures persistently returned. For a well-formed stricture of the rectum he knew of only one method of cure, and that was extirpation. Dilatation came next in importance. He had never seen a case of posterior proctotomy in which the stricture had not returned in time. After much study and experiment on the cadaver he had become firmly convinced that it was impossible to introduce the Kelly tube into the descending colon.

Dr. Frederick Kammerer said that his personal experience had been that he had never seen a well-developed rectal stricture that was not syphilitic. Of course, by a "stricture" he meant a narrowing of the rectum sufficient to give rise to symptoms. He had occasionally obtained a good result from posterior proctotomy, being able to keep it in abeyance by dilatation. Resection of a large stricture of the rectum was an operation of much difficulty and danger, and therefore he would favor posterior proctotomy as a first resort. Resection of the stricture itself was also sometimes followed by stricture.

Dr. Tuttle explained that he would not recommend resection of the rectum except in cases that did not prove amenable to milder measures.

Dr. Palmer Heath Lyon recalled a well-developed stricture of the rectum seen recently in a patient upon whom a homœopathic practitioner had endeavored to operate for the relief of hemorrhoids by injecting them with carbolic acid. In this case there had been no evidence of the stricture being other than of traumatic origin.

Dr. Bullard, in closing, said that he was not yet convinced that syphilis was the cause of rectal stricture; to his mind, adequate microscopical proof had not yet been presented. No case had yet been reported in which there had been degeneration of the embryonic nucleus, which was essential in a syphilitic gummous formation. If some rectal strictures were due to gumma, then it should be possible for pathologists occasionally to find these gummata.

Opinion of Legal Counsel on the Case of Drs. Purdy and Maier.—Robert C. Taylor, Esq., counsel for the society, having been asked for his opinion on the recent arrest of Dr. Harry R. Purdy and Dr. Otto Maier, and as to the best means of preventing such outrages in the future, replied that it was his opinion that the police captain had acted entirely without regard to the law, and that these physicians had a right to bring a civil suit against Police Captain Delaney. Regarding the circumstances of the arrest, the statement was made that physicians were not specially liable to unjust arrest, as witness, for example, the frequent arrests of drivers and motormen in connection with accidents occurring in the streets, such arrests being made entirely without warrant. In the judgment of counsel the trouble was not with the law, but with those who administer the law in this city, and consequently the remedy was not to be found in amending the present law. Instead he would recommend that a formal communication be addressed to the police department, setting forth the circumstances of the case under discussion. This might result in a general order to the police captains regarding the future conduct of cases of this kind.

As a committee had been appointed by the New York County Medical Association to consider this same case, a joint meeting of the two committees had been held. Dr. John Blake White, of the latter committee, sent a communication stating that the committee had agreed to recommend the following resolution:

"*Resolved*, That it is the sense of the committee that a vigorous protest be sent to the various medical societies of Greater New York, to the commissioners of police, and to the board of coroners, condemning the unlawful arrest of Drs. Purdy and Maier, two physicians of reputation and standing in the community, and requesting the board of police to instruct the police captains to exercise greater care in the future where reputable physicians are concerned, before making arrests."

Action Taken.—On the recommendation of the comitia minora the society voted to send a communication to the board of police, requesting that more care be exercised in arresting physicians on suspicion only.

STATE CARE OF CONSUMPTIVE POOR.

Hearing before a Committee of the State Board of Charities, at a Meeting Held in New York, December 13, 1899.

Dr. George G. Wheelock: I believe in the establishment of a State sanatorium intended exclusively for incipient cases. This should be located, I believe, preferably in the Adirondacks, where perhaps the State could allow a portion of the forest reserve for the purpose. I say in the Adirondacks by preference, because there is in the State nowhere else a similar expanse of nearly continuous forest growth, with but little cultivated soil, located in pretty high altitudes; and experience also has shown, gathered from the highest medical authorities, that up to the present time patients coming from a residence for cure in the Adirondacks have shown better conditions of improvement and restoration than those in a similar stage of the disease coming from other climatic resorts. The question of distance is not a vital one, inasmuch as all patients should be expected to remain at least six months; and a single trip of a few hours more or less only would have to be considered. Moreover, not all places in the State are as far removed as is New York City from the Adirondack Mountains. If our purpose is to cure and not merely relieve, the best climate should be found for the purpose. As to the outlay called for, I believe not less than $200,000 should be asked for, as was contemplated in the bill of last year. It would be a mistake to begin with an inadequate appropriation.

In this connection the subject of the Farm Colony should be considered, as the criticism of that plan will help to emphasize the reasons for selecting the Adirondacks in preference to the Catskills, or even Liberty, in Sullivan County. The Farm Colony can hardly be compared with the Craig Colony, for in the latter employment is the means of promoting a cure, while with tuberculous patients nearly absolute rest in fresh air is the prime requisite. Reduction of temperature and arrest of tuberculous processes have been found after many trials to be impeded rather than aided by manual labor; hence the occupation of a spot where there is arable land is not a necessity, and the less arable land there is about—as in the Adirondacks—the better is the atmosphere for curative purposes.

If as a means of keeping the family together the Farm Colony is proposed, it would certainly seem wiser not to advocate it for several reasons, viz.: (1) The family members are nearly if not quite as much in contact with the patient as in their city home; hence infection, which we seek to avoid. (2) The State would hardly be likely to pay for the support of a family as well as the patient, and we have seen that work such as would support a family is bad for the process of cure. (3) If the family are kept together it increases the chances of the birth of feeble children, who, in turn, will perhaps become victims.

As to location, I may say that the late Dr. Loomis, who originated the sanatorium at Liberty—himself a victim to the disease—always went for his own cure to the Adirondacks.

I think the suggestion a wise one to urge the building of hospitals for advanced cases near the cities, where tuberculous patients may die comfortably, remembering also that as the disease advances the dangers of infection of those in the immediate vicinity increase rapidly; and hence, for the comfort of the dying as well as the preservation and protection of the family, the patient's removal from home is desirable, and we know that few private hospitals will receive him—hence the need of public institutions. Having arrived at the above conclusions myself, and being anxious lest they were not fully established, I saw my friend Dr. Trudeau a few days since, whose experience and faithful care of tuberculous patients are surpassed by no one in this country, and whose patient and intelligent study of the disease over a period of years has brought wisdom. We went fully into the above topics, and I am happy to say that he confirmed in every particular the views which I have expressed.

EDWARD T. DEVINE, general secretary of the Charity Organization Society: Three distinct but not incompatible methods of fighting tuberculosis are advocated: First, more strict dietetic and therapeutic treatment of individual patients in their own homes, accompanied by educational work to prevent such contagion as can be prevented by reasonable care on the part of the patient. Second, the isolation of advanced cases, which are, of course, the most dangerous as centres of infection, the object of such isolation being merely to insure better care for destitute patients at the end of their lives and the elimination of contagion. Third, the isolation and curative treatment of incipient cases.

There is entire agreement about the first two methods. It has been demonstrated that many cases of tuberculosis are cured in their own homes, even in cities, and there has been great advance in the possibility of diagnosing consumption in its early stages. Aside from increased vigilance in the medical profession in the treatment of individual cases, what remains to be done is the circulation of suggestions and information through printed leaflets, public addresses, instruction in schools, and advice given by church and charity visitors.

The plan of isolation hospitals for advanced cases meets with equally unanimous indorsement. In New York City Seton Hospital and the wards recently set apart in the almshouse hospital are achievements already secured in this direction, and the prospective removal of insane patients from Blackwell's Island will give increased opportunities of which the department of charities will doubtless be quick to take advantage. If these facilities are not sufficient, and if it becomes necessary, the Henry law authorizes the city to arrange for an isolation hospital outside the city limits. Increased facilities for caring for such patients are still imperatively needed, but the indications are that the rapid progress of the past year or two will be continued until there is something like an adequate provision for the need. It is only when the plan of caring for incipient cases by a State institution is proposed that there arises difference of opinion, and this on close examination is found to be a difference of emphasis rather than of principle.

A State sanatorium for incipient cases is urgently needed in addition to all that can be done by local isolation hospitals and by improved treatment of patients in their own homes. It is needed, first, because it will cure a large number of patients who cannot be cured at home, and whom it is a disgrace to the community to leave until they are fit subjects for the isolation hospital. In the sanatorium proper diet, favorable climatic conditions, the absence of severe physical labor can all be secured, and incidentally the patient can be taught lessons which will be useful to him, to his family, and to his neighbors. The saving of lives in this way has a direct money value to the State, as is recognized by our attempts to prevent murder, to protect from fire and other public calamities, and by ample precedents in other directions. If nothing else could be said for the State sanatorium than that it would save annually a dozen lives by curing consumption in its early stages, this would be ample justification for the proposed expenditure. This is especially true since its object is not to prolong the lives of those who have at best a few months to linger, but in many instances those who are young and strong and who on being cured of their incipient disease may live long and useful lives.

Second: Of all the objects which the State may legitimately pursue, none is more clearly justified than the safeguarding of the public health from contagion and from such diseases as are due to social causes rather than to the neglect or misfortune of the individual. This is recognized in the efforts made in every progressive community to secure a pure and healthful water supply. The resident of the country may perhaps dig a well and secure water for his own family without either the consent or the aid of his neighbors. Residents of cities and towns, however, are entirely dependent upon the conclusions which may be reached and the action which may be taken by the community as a whole. If the water supply is tainted or defective he has no recourse within himself.

Even those who are the most extreme opponents of paternalism and the most earnest advocates of sturdy individualism concede that there are numerous duties thus devolved on the State or its political subdivisions, and that among these the protection of the public health from dangers which lie in social conditions is perhaps the foremost of all. It becomes, therefore, a question whether there is especial danger from consumption marking it out as a disease which should be attacked vigorously and by every means at the command of society. The facts that have been brought out in regard to this by the vital statistics, by the discussions in medical periodicals and in medical societies, and by the experience of those who work in public and private charities, are perfectly clear and are admitted on all sides to be appalling. It is not necessary to enumerate them. Tuberculosis claims so large a number of victims relatively to other diseases that it stands without rival as the great scourge of mankind. It is in its incipient stage curable; it is in all stages communicable. The duty of the State, therefore, to expend large sums if necessary, and certainly to expend the moderate sum contemplated for the establishment of one State sanatorium stands out more and more clearly the more the subject is examined. Its victims are by no means the poor alone. That it has claimed one member of the State board of charities since the present investigation was begun, and that in every discussion of the subject, even in the smallest group, it is necessary to use discretion on account of the sensitive feelings of those whose immediate kindred already bear its mark, are a sufficient indication of its universal and as yet unchecked way. Yet it is to a large extent preventable, and awaits only aggressive, intelligent, and courageous action. Half-hearted measures will not suffice. There are no such poverty-stricken condition of the State and no such rival claims upon its resources as will excuse our dallying with the problem. One need not be a socialist to favor State action in matters of this kind, while the fear of being charged with paternalism in the face of an obvious public duty is as absurd as would be the charge of militarism if the nation were to expend money for coast defences in the face of an actually impending invasion. The State sanatorium would not merely save some lives and restore to life and activity a certain number of human beings each year. It would also be an experimental station in which our knowledge of how to treat the disease would be constantly advanced, and which would be a constant source of inspiration and information to the great body of the medical profession, on which we must, of course, chiefly rely. It is only by limiting in this way the various complications which are always present when patients are living at home, and especially when they are engaged in their ordinary occupations, that the disease can be closely observed and the effects of different kinds of treatment can be positively ascertained.

Private sanatoria are excellent in their way, but they are for the rich or for the limited few for whom private assistance is forthcoming. Not all of the remainder who should be treated can be induced to give up their work and to be absent from their homes for the period necessary to secure results in a sanatorium, but throughout the State there are many who would be able to make special arrangements of this kind and who could be persuaded to do it when they realized that their lives are at stake. Even the hard-working mechanic who has a family to support will often be able, by the help of relatives and friends it may be, to leave his family for six months, and he can be persuaded to make the necessary sacrifices to do this if he realizes that the present temporary absence may mean, and possibly will mean, that he can continue to support his family for many years and to bring up his children, whereas if he does not have this opportunity they will be left within a year or two entirely dependent and without their natural support. Of course, not all can do this. Otherwise the problem would be unmanageable. By caring for the limited number who could be received under conditions favorable for good results we shall benefit not merely them but the communities in which they live, and this would be done not merely by restoring them to lives of usefulness, but by preventing the development of an advanced case of tuberculosis with all its dangers.

The question remains where the State shall draw the line. The only answer to this is that there is no absolute dividing line between what the State should and should not undertake in the protection of the public health, but that the question must always be one of expediency, in which the conclusions will be reached by balancing in a rough way the cost of prevention and the cost of failure to act. So far as tuberculosis is concerned the cost of acting is reduced by the fact that in the Adirondack preserves, and possibly also in other sections, the State has a valuable working capital already in its possession. There is some dispute as to whether an unfavorable climate or the proximity of cultivated land, or the presence of large numbers of cattle, is chiefly responsible for the presence of tuberculosis in districts where population is congested. Whichever view is correct, we are remarkably favored in that the Adirondack region has a suitable climate if there is such a thing, has a large uncultivated tract which many believe to be an especially valuable consideration, and it is a community in which it is easy to take any necessary precautions regarding contagion, from the small number of cattle necessary to supply the needs of its limited population. Other States with far less taxable property have not found the expenditure for a sanitarium burdensome. With our advantages in the particulars mentioned the burden would be still lighter upon us. On the other hand there is no State in which the frightful cost of failure to act is as great as here. With crowded populations at both ends of the State and with the great majority of our population living in cities, with our supply of fresh milk necessarily coming from at least three States, and with the meat supply of most of our population coming from many States, there are some phases of the problem with which it is especially difficult for us to deal. It becomes the more important that we shall adopt such measures as lie within our power.

Citizens of the State as taxpayers naturally look to the State board of charities to sound a warning note against extravagance or abuses of any kind in the State charitable institutions. To act in such ways as a watchdog of the public treasury is an exceedingly useful service which will always be appreciated. On the other hand, it is quite as important that the State board of charities shall carefully consider the public needs of the State, and shall sound a note of warning when the State is neglecting or omitting to do what the public interests require. This may require greater courage, but it is a kind of leadership which will in the long run be appreciated by the citizens of the State quite as much as protection against extravagance. Justifiable expenditure for a necessary purpose is not extravagance, and a responsible board to which the public looks for leadership should no more be frightened by a false and misleading cry of extravagance than by the equally false and misleading charge of a tendency toward paternalism. Those who are interested in the welfare of the poor, and who believe that the State is neither extravagant nor unduly paternal when it takes reasonable precautions to ward off from them their most insidious and dangerous foe, look now to the State board of charities for aid and encouragement in the establishment of a State sanatorium for incipient cases of tuberculosis.

Dr. Alfred Meyer: The answer to the question, Shall or shall not the State lend its aid to the consumptive poor by the erection of properly located and properly equipped sanatoria? will depend, in my judgment, upon the answers given to three cognate questions: (1) Is it or is it not better for the consumptive poor to remove them from their unsanitary surroundings and to place them under medical supervision with attention to all the details of hygienic living? In other words, do they or do they not have a greater chance of recovery in the country under continuous medical supervision, than in the crowded centres with an occasional visit from their lodge physician, a visit to the dispensary or to the hospital? This is a distinctly medical question. (2) Is there or is there not some constitutional objection to State aid in New York? This is a distinctly legal question. (3) Is it or is it not expedient for the State to exercise this right, if permitted so to do by the constitution? This is a distinctly sociological question.

Unless we say that American consumption differs from the consumption of other nations, the first question must, I believe, be answered in the affirmative, because of the accumulated experience of medical men the world over. For, whatever difference of opinion there may be upon the question of the relative value of altitudes, the relative value of dryness and moisture, and of other meteorological conditions, there is general agreement upon the need in these cases of abundant fresh air and light, and good food, and intelligent supervision, and the greater probability of recovery if these conditions are fulfilled. It is the sifting down of the treatment to these primordial hygienic principles that has shown us why our efforts in the great population centres are so futile; but, though the road we should follow has been clearly pointed out to us, it is only the well-to-do citizen who can follow it. It will not do to answer, as some have done, that patients sometimes get well under bad surroundings, while they continue at work and have only occasional medical advice. You might as well say there is no need of guard rails in front of a trolley-car because occasionally a citizen escapes being hit and run over by the exercise of unusual agility; or, to make a more distinctly medical comparison, that there is no need of disinfecting the dejecta of typhoid-fever patients because at times this wise precaution is neglected with impunity. Though exceptions have their value in teaching us lessons and in enlarging our views, they should not be mistaken for the rule or blind us to the fact that they are exceptions. Nor is it just to characterize those interested in this movement as dreamers—though to be called such is not always a reproach, for often the dreams of one age are the facts of the next. But it is not dreaming to accept the teachings of science; it is not dreaming to accept the evidence of the post-mortem table that pulmonary tuberculosis is a curable disease; it is not dreaming to listen to the testimony of medical men of every country as to the essentials of treatment; it is not dreaming when modern civilized communities devise methods for alleviating the suffering and disease of the unfortunate in their midst; nor is it dreaming to say that pulmonary tuberculosis is by all odds the greatest scourge with which we have to deal. We are not holding out for ourselves any false hopes; we know that man is born to die, and that he will continue to die whether we have a State sanatorium or not; but we feel that we are awake when we are trying to make practical application of the things that have been learned in the last fifty years—that we are awake, yes, wide awake, when, in the language of one who has advocated this movement, we wish to care for the patient in the right place, at the right time, until he is cured, rather than in the wrong place, at the wrong time, until he is dead.

With reference to the legal aspect of the question I believe no objection has been raised against the State sanatorium. Neither in the Senate nor in the Assembly did any of the numerous members of the legal profession in those bodies assail the bill on account of its supposed unconstitutionality.

With reference to the third question, the expediency of this measure, I believe, after what has been said, that this must also be answered in the affirmative. Or should the great and wealthy State of New York hesitate because it involves the expenditure of a paltry $200,000? What are $200,000 compared to the untold advantages of suffering alleviated and of lives saved to the State? It almost seems sacrilegious to figure in money value the dead who might have been saved to the State during the past year. And yet, in view of the fact that reasons of economy prevented the success of this measure last winter, I may be pardoned for making this calculation. So far as I know, the only clew as to how high the State of New York values the life of a citizen is the statute now repealed permitting the heirs of a citizen dead by violence to sue for $5,000. Now if only one out of every fourteen of the fourteen thousand consumptives who died last year had been saved, the sum total measured by this standard would have represented a saving to the State of $5,000,000.

With reference to the expediency of such a movement as this, we must also be guided by the stand taken toward it by medical societies and by private philanthropic and charitable organizations. So far as I know, there has not been any opposition on the part of any organized body of men or women, lay or professional. On the other hand, the movement has been indorsed by the New York State Medical Society and by the Section on General Medicine of the New York Academy of Medicine. This was done at a meeting of the section held at the Academy on October 17th last. The interest in this matter was shown by an attendance larger than that on any other evening in the past three years; a number of medical men from neighboring States expressed themselves favorably upon this movement, and the resolutions adopted were practically an indorsement of the Massachusetts State Hospital for Tuberculosis, the first of its kind to be opened in this country, and an indorsement of the movement for a similar institution in this State. In all candor I must add that the full Academy has not as yet passed judgment in the matter—the resolution will not come up for action until next week.[1]

With reference to the expediency of this movement, one other objection must be answered. There seems to be a fear that the opening of a State sanatorium for tuberculosis will encourage the opening of State institutions for a multiplicity of diseases. The question is asked, Why not a State hospital for cancer? And if not, why not? I should answer that every bridge will be crossed when it is reached—that the intelligent public opinion of this State will settle each question as it arises, on its merits and intelligently; and that not until it is made clear that cancer is as prevalent among the poor as tuberculosis, that provisions for its care are as inadequate as they are for tuberculosis, and that cancer is as much a menace to the healthy citizen as cases of tuberculosis—not until then will there be that intelligent sentiment behind the demand for its State care that there is to-day for the State care of tuberculosis.

DR. S. A. KNOPF: As to the danger arising from tuberculous patients there seems to be a general idea that the more advanced and hopeless cases are a greater danger to the community than the early ones. This assumption is a mistake. The advanced hopeless or even helpless case is confined to his room, and the danger of infection is limited to his immediate environments. On the other hand, the tuberculous patient who is still able to be up and about, and who often pursues his daily occupation, has an opportunity to expectorate anywhere, and thus propagate the disease to a greater extent than his brother consumptive confined to his bed. From this it is evident that the need of institutions for incipient cases is as important as for advanced ones. While we may congratulate ourselves on the willingness of the State to create one institution for either incipient cases or advanced, let us hope that through a combination of State and private charity we will soon have a sufficient number of institutions of both kinds; for only through such methods can we hope to cope successfully with the tuberculosis problem. That the expense of maintaining a patient in a sanatorium is not any greater than in a general hospital, may be seen by the following figures: The daily cost of a patient in the general hospitals of New York under the direction of the commissioners of charities is $1.16. In the Adirondack cottage sanatorium it is $1.

---

[1] Since this was written the Academy of Medicine, at a general meeting held December 21, 1899, adopted resolutions favoring the establishment of both State and municipal sanatoria.

DR. VAN FLEET: The Adirondack bill of last year was very strongly urged by our committee, and especially by our representative in Albany, Dr. Root, who did nearly all the work. All physicians recognize the necessity of some sanatorium of this kind. The objections to the bill of last year were, first, the item of expense, and, second, that it dealt only with incipient cases. Speaking as an individual, this matter presents itself to me in a different form than it seems to present itself to others. The State should not go into the establishment of a sanatorium through any philanthropic motive. The only justifiable reason for the State would be that of self-protection. If the State is going to all this expense for a few, it is unjustifiable. But if it is going into this matter for the treatment and isolation of all cases, in order to prevent the spread of this dreadful disease as a matter of self-protection, then the State has no right to stop at the question of expenditure. The cost of doing is only to be compared to the cost of not doing. The choice of the Adirondacks for the site of the sanatorium is a very good one. The Henry bill allows cities to establish sanatoria outside their municipal limits. This should not be, as you cannot go outside the limit of one municipal corporation without coming into the limit of some other municipal corporation. [This statement was corrected by the chairman.] The object of the Henry bill was that a certain menace to property values in Spuyten Duyvel might be removed. The State has a vast tract of land in the Adirondacks, where a sanatorium could not injure anybody. This seems to me a very strong point. Another objection is a purely sentimental one. If the State goes into this thing for self-protection, it has the right to demand that all these cases be reported for the protection of the rest of its citizens. They ought to be obliged to go to the sanatorium, and be taken away from the crowded sections of our towns and cities. I am heartily in favor of a measure of this kind, and the institution should be situated so that it cannot interfere with the rights of others.

There was no work for our committee to do after the adjournment of the legislature. The matter will come up again at the next meeting.

Tinnitus Aurium is regarded by Robin and Mendel (*Memorabilien*, July, 1899) as due to direct or reflex irritation of the auditory nerve. For its relief they recommend the fluid extract of cimifuga racemosa; gtt. xxx. pro die being a moderate dose. According to the observation of these authors, this drug has a sedative effect upon the aural circulation as well as upon the auditory nerve.

Correspondence.

LETTER FROM NAPLES.

(From our Special Correspondent.)

THE UNIVERSITY OF NAPLES MEDICAL SCHOOL—HOSPITAL INTERNES—NEED OF TRAINED NURSES.

NAPLES, December 18, 1890.

A MEDICAL degree is conferred by the University at Naples after six years of study. The first year physics, chemistry, and descriptive anatomy are the only obligatory subjects. The course for the second year comprises zoölogy, botany, and comparative, physiological, and descriptive anatomy. In the third year human, descriptive, and preparatory (much like our regional) anatomy, human physiology, and general pathology are studied. The remaining three years are given over to clinics, with therapeutics, hygiene, and special pathology in addition.

The clinical material here is, of course, immense, and the students have many more opportunities for practical work in surgery than is possible with us. One of the reasons for this is that there are no trained nurses, and the student does the work of the nurses and assists at the operations constantly.

There are two thousand men now taking the medical course. Women are admitted on equal terms, but few have availed themselves of the opportunities, eight only having taken degrees here, and these are nearly all Russians. At the end of six years the men are considered qualified for hospital positions, which are given to those considered by their friends to be most fit. Their positions correspond to nothing in America, for the doctors have their offices outside and attend to any private practice. A certain number of men are chosen for each division, not necessarily from the graduating class. Some may have been physicians for one or two years, and each one remains in the hospital a given night during the week. Most of the men are about during the day for a few hours, when operations are to be done by their chief, and they have most of the minor operations to perform. Many major ones also fall to their lot.

Surgery is apparently much more advanced than medicine, their methods in this branch being those of the best German and English schools.

Morisini and Spinelli are perhaps the leading surgeons in gynæcology among the older men. Very little work is done here on malaria, all of the best-known men being in Rome. In fact, there is absolutely nothing in Naples for American students. Nursing is only a name, the work being done mostly by a very low class of servants, who have no training whatever, and by the Sisters of Charity. This is true of all hospitals except a few small wards at the "Gesù e Maria," where Miss Baxter, a young woman who took her course at Johns Hopkins, has established a small training-school (during the three years of its existence eleven nurses have been graduated), and these little wards show plainly enough the traces of her splendid efforts.

DISCOURAGING EXPERIENCE OF A PUBLIC-SPIRITED CITIZEN.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The MEDICAL RECORD is eminently qualified and ever prompt in challenging the rights and upholding the dignity of the profession, as was so recently illustrated by its able editorial of November 4, 1899, "An Unpardonable Indignity," defending Drs. Purdy and Maier. Your strong protest against such a flagrant outrage certainly meets with the approbation of every honorable member of our noble profession. As evidence of this, witness the manner and spirit with which the leaders of the profession came to the rescue, as revealed in your correspondence column of your issue of December 16, 1899.

It is only by concert of action we may hope to enact and enforce laws to protect us from dangers within and without the profession. To illustrate, I am here prompted to report my very recent experience in a case in which I attempted, in a legal way, to enforce the law that bears on empiricism in Kentucky, to wit:

Last May, by the advice of the county attorney, I had a warrant issued for the arrest of a man for violating the law and he was released on his own recognizance until the time of trial, which was made a commonwealth case. The first trial resulted in a hung jury, although ten of the jury voted for fining the accused. On the second trial he was acquitted, as a result of the testimony of three of the local physicians, one of whom, strange to say, is on the county board of health, who testified in favor of this notorious quack.

This would have ended the matter had not one of the above physicians inspired him to bring suit against me for malicious prosecution. The man admitted on the witness stand that he had been in communication with one of these three physicians, and further admitted that if I had any malice toward him he was not aware of it.

My attorneys motioned for peremptory instruction by the judge for the jury to dismiss the case on the plaintiff's own testimony, and absolute failure to show malice. However, the case was allowed to go to the jury, who flagrantly disregarded the plain law and evidence, and rendered a verdict for $500 in favor of plaintiff. Of course I will appeal. MEDICUS.

Medical Items.

Pectoriloquy. — Pectoriloquy — so named by Laennec, its discoverer—is a complete transmission of the voice to the ear. The words spoken are heard distinctly articulated. It closely resembles the resonance heard over the larynx, and is usually limited to a small space in the chest, where it also may or may not have a hollow, ringing character. It was formerly believed always to indicate the presence of a pulmonary cavity, but auscultators are now agreed that this is not necessarily the case in every instance, but that it is sometimes simply an exaggerated bronchophony; the only distinction between these two being that bronchophony is the transmission of the voice, pectoriloquy that of the speech. Well-defined pectoriloquy is not a common phenomenon.—LOOMIS: "Lessons in Physical Diagnosis."

Quinine Making in Bengal.—Major Prains' interesting report for 1898-99 has recently been published. The total number of living plants in stock amounts to considerably over two millions. The out-turn of the factory was 10,335 pounds of sulphate of quinine and 3,921 pounds of cinchona febrifuge. This large amount is absorbed in the issues to the medical store depots at Calcutta and Mian Mur and to the Alipur jail, for manufacture into "pice packets" for sale through the post-offices. Another large amount was sold to hospitals and dispensaries and to the public. There appears to be no quinine exported to other countries.—*Indian Medical Gazette.*

Why Quackery Succeeds.—In concluding an address upon ancient and modern quackery, Dr. Eden says in *The Lancet*, November 18th: "In the earlier days it was inevitable that such primitive methods as were then known should often fail, but it is a reproach to us that with all our boasted scientific progress the practice of the healing art, except in the domain of surgery, is making such scanty advancement. We are all so keen on scientific problems that we are apt to lose sight of the fact that in the eyes of our patients our value mainly depends upon the amount of relief which we are able to bring them. What they expect from us is not an elaborate diagnosis or a learned discourse on their disorder, but simply something that will do them good. One of the most accomplished physicians whom I have ever known took little or no interest in his patients between the stage of clinical diagnosis and that of post-mortem examination. That is the kind of medical attendant from whom people flee to find refuge in a quack. I take it that our duty is to spare no pains and leave no method untried which promises to be useful in combating disease, for we shall be ultimately judged, not by our academic distinctions or our contributions to science, but by the measure of success we have attained in discharging the task which society has committed to us—namely, the relief or mitigation of suffering and the preservation of health."

Appendicitis Said to be Caused by the Habit of Crossing the Legs.—A foreign surgeon has put forward the suggestion that appendicitis is caused by the habit of crossing the legs, which restricts the action of the digestive apparatus. The appendix is only loosely attached to the cæcum, and there is always some half-digested food in the cæcal bag. By crossing the legs there is liability that the undigested food may pass into the vermiform appendix and set up inflammation; in a few hours pathological processes set in, and an attack of appendicitis is developed.—*Scientific American.*

Fortune Making by Hypnotism.—Occult influence as a road to wealth may appeal to many people as being a fantastic notion born of a wild freak of the imagination (writes a well-known English lawyer), but I can tell you that in recent years various sciences bordering more or less on the occult have played an all-important part in many a stirring but unrecorded legal drama, and that mysterious agencies are much more resorted to in order to gain the ends of unscrupulous persons than the public is aware of. One instance I have in my mind among others was that of a retired business man whose will I proved not long ago, and among the bequests was one to his medical attendant for £5,000 ($25,000), a larger sum than had been left to any of the testator's own family. It would be too long a story to go into all the remarkable facts of this case, but for months previously the doctor and the patient were continually together. The doctor had something of an uncanny reputation as being a believer and dabbler in occult science, and under his tuition the man of business soon became a convert and consented to various hypnotic experiments being tried upon him, with a view to the benefit of his health. His sudden death came as a great shock to his relatives, but they experienced another shock when they found that the doctor had been made executor and chief legatee of his will.

Escape of Cerebro-Spinal Fluid from the Ear after Injury.—That the cerebro-spinal fluid can escape from the cranium in cases of injury has been known for some time. As early as the year 1727, Stalpartius van der Wiel published a case in which large quantities of a thin, clear, watery fluid had escaped from the ear for several days after a severe injury to the head. O'Halloran and Dease published cases, but these appear to have been lost sight of until Langier called attention to the coexistence of a watery discharge and rupture of the membrana tympani in some cases of fracture of the base. The character of the fluid was not recognized at first, but it was established by Nélaton, Robert Rabourelin, Chatin, and Deschamps. Guthrie held that the fluid probably came from the cavity of the arachnoid, and pointed out that it was symptomatic of great danger. This accident is now of course a matter of common observation. —St. Clair Thomson.

Smoke of Burning Leaves Injurious.—The board of health of Plainfield is considering the question of adopting a rule which will prohibit the burning of leaves within the city limits, as it is claimed that the practice is conducive to much ill-health during the fall season. Several physicians have said that the smoke and smudge which come from burning leaves are the causes of many of the ailments of the throat, lungs, and eyes.—*Scientific American.*

Meat and Cancer.—The question how far the increase of cancer among the more highly civilized nations, which has appeared so marked during recent years, is caused by the greater quantity of meat which is eaten in prosperous countries, is a matter of very considerable interest. That man is by nature not a vegetarian, in other words that he is naturally not a mixed feeder, may be taken as pretty certain; but it is also certain that as the result of hard necessity meat has generally in times past been to him a luxury, and has but rarely found a preponderating element in his diet. But with prosperity and with the greater ease with which animal food can now be obtained we find whole nations falling upon meat as a necessary ingredient of their daily diet; and in the very nations among whom this change is most noticeable we are told that cancer shows the greatest increase. In support of the connection between meat and cancer Dr. Roger Williams points to the rarity of cancer in prisons and workhouses where but little animal food is allowed, and hard work is exacted. He has lately found additional evidence as to the small amount of cancer among the convict population, which he says strongly supports this view. . . . We need scarcely say, however, that convicts are a somewhat "selected" class of people, and that diet is not the only matter in which convicts differ from those outside prison walls. —*Hospital.*

Typhoid Fever in South Africa.—Professor Sambon, writing in the *Journal of Tropical Medicine*, says: "Typhoid fever is the most prevalent and fatal disease in South Africa. In the Galeaka Gaika war it was stated by the principal medical officer to have been undoubtedly the most serious disease during the war. In the Zulu war of 1878 typhoid appeared at the headquarters at Helpmakaar and at Rorke's Drift in the middle of February, accompanied by diarrhœa and dysentery. Helpmakaar became so unhealthy that it had to be evacuated. The troops were moved to Utrecht and Dundee, but the fever immediately broke out at both these places. . . . It is an almost unanimous opinion that all outbreaks of typhoid may be traced to the polluting of the water supply by the excrements of a typhoid patient. I do not contend in the least that water may not be a vehicle, and possibly the principal vehicle, of typhoid infection, but I think it is very obnoxious to generalize a theory, however plausible it may be. Indeed, there are many outbreaks that cannot receive so comfortable an explanation. Some of them are strikingly limited, and their limitation is rarely in accordance with the distribution of the water supply supposed to be polluted. Dr. James Allen, of Pietermaritzburg, from his observations in South Africa came to the conclusion that typhoid fever depended chiefly upon infected cattle. He describes a specific enteritis occurring in calves, subject to relapses and very contagious, and holds that the excrements of animals affected with this distemper, on gaining access in any way into the human body, will give rise to typhoid fever. He holds that typhoid fever thus arose in a great measure among the British troops in the Zulu war."

French Regulations Against the Use of Lead Oxide.—In France, says the *Sanitary Record*, we understand a regulation exists making it illegal to use lead oxide in glazing pottery. It was interdicted by a ministerial circular so far back as 1878, but the regulation has been practically allowed to remain a dead letter. For this state of things the manufacturers are not wholly to blame. The ultimate responsibility rests on the shoulders of the public, who prefer ware glazed by means of lead because it is cheaper.

Excision of Bowel for Malignant Disease.—Treves, in his work on intestinal obstruction, says: "I would estimate the present mortality of excision of the bowel for malignant disease at about twenty per cent., and the mortality of short-circuiting operations at about twelve per cent. It is to be remembered that the majority of these operations concern the colon. As in like measures for other forms of obstruction, the great element in success depends upon the performance of the operation at the earliest possible period. The danger in an excision of the bowel or in a short-circuiting operation is to be measured mainly by the degree of distention of the bowel at the time of the operation. When abdominal section is performed as early as possible the mortality of the operations in question will still further decline. The mortality of colotomy performed for chronic intestinal obstruction may be placed at between five and ten per cent."

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended December 5, 1900:

		Cases.	Deaths.
SMALLPOX—UNITED STATES.			
Dist. of Columbia, Washington	December 22d	5	
Illinois, Cairo	December 23d to 30th	12

COMPARATIVE STATISTICS IN THE TREATMENT OF APPENDICITIS.

By EDWIN MARION COX, M.D.,
NEW YORK.

There is very frequent comparison by statistics of the medical with the surgical treatment of appendicitis, and to the superficial observer the medical men sometimes seem to make out a fairly good showing for what many of them like to call the conservative method. We are also occasionally offered "new" methods of treatment, the chief part of all of which is avoidance of operation. Many series of cases have been reported with a mortality of from eight to twelve per cent. in which a non-surgical form of treatment has been employed, and the reporters have seemed to ask, apparently with a touch of pride, whether the surgeons can show any better results. There are several objections to the accuracy and fairness of such series, seemingly not often enough or strongly enough emphasized. For example, one series, that of Sahli, consists of 7,213 cases from Swiss sources, among which 473 were operated upon with a mortality of twenty-one per cent. and 6,740 treated without operation with a mortality of 8.8 per cent. It is admitted that recurrence was observed in 20.8 per cent. of these cases, but the observer does not give the period during which the cases were watched, and of the cases represented by the 8.8 per cent. mortality we do not know how many could have been saved by timely surgery. Other advocates of the medical treatment, mostly foreign, offer approximately the same results, in some instances with even less mortality for the treatment they prefer. The first element in such series that attracts the attention of the American surgeon can hardly fail to be the high mortality after operation, explicable only by a close analysis of the figures, unless we wish to say that Europe has not reached the same proficiency in treating this disease as America. The medical man usually sees the patient with appendicitis before the surgeon, and in many instances the latter never sees the patient at all, so that there is no opportunity afforded him to say whether in his judgment operative treatment at once or later would be suitable. Many such patients pass through the attack and live to have another, within or without the ken of the first physician. Others are treated for several days by medical means until the physician calls the surgeon, perhaps too late to save life, and at best with a very good chance of increasing the mortality figures to which the physician objects so strongly in the records of the cases treated by operation. The advocate of medical treatment seems to assume always that the surgeon would operate upon every case of appendicitis almost at once, and therefore feels justified in classing every patient who survives an attack as cured by medical means, either forgetting or ignoring the fact that the surgeon is continually seeing more or less mild cases in which he advises waiting either for a return of symptoms or until a suitable time after the subsidence of the attack, for operative treatment. The medical statistician assumes the right to keep any of these cases under his observation as long as he sees fit, and then to call the surgeon, saying: "All that medical treatment can do has been done; now let surgery save him." He assumes also the right to place in his list of cures mild cases of the so-called catarrhal form of the disease, omitting to consider that such are not cures when there is a large percentage of recurrences, and that in many cases operations are done for subsequent attacks, often with diminished prospects of good result on account of inadequate treatment in the first instance. A further, though less important, source of inaccuracy in drawing conclusions from the statistics of appendicitis is error in diagnosis. Several mild inflammatory processes in the right iliac fossa simulate appendicitis, and recoveries might easily be placed in a list of cures, to the material reduction of the mortality percentage. The reason that a surgeon is less apt to be led into errors of this sort is that surgeons are usually called to see suspected cases of appendicitis because they are known to have had experience, and are therefore, in this particular condition, less likely to be deceived than the less experienced medical observer. The only fair means of comparing the surgical results with the results of cases treated without operation would be the impracticable arrangement of comparing two large series of similar consecutive cases, one treated in each way. I think that one series would very quickly develop cases which would require surgical aid, unless the medical men were prepared to take the responsibility of unnecessary deaths. It is obvious that death should not be attributed to the operative method of treatment in cases in which that treatment is undertaken under stress of emergency, and not at the time that the surgeon would have chosen. The opponents of the operative treatment of appendicitis have in some instances assumed the entirely unjustifiable attitude of doubting surgical statistics offered by men of good repute, with what reason is not clear. There is not the slightest doubt that in competent hands the mortality after the removal of the diseased appendix in suitable cases during the quiescent period is practically nothing, and that in acute cases of various kinds (abscess, perforation, etc.) the figure is much lower than any medical form of treatment can possibly show, and will become still lower in proportion to the recognition which timely surgery receives as the only proper way of handling the disease.

The obvious physiological disadvantage under which the normal appendix must work in order to keep itself free from intestinal contents must be clear to any one who has ever seen an appendix, but the great increase in these disadvantages which occurs after an attack of inflammation is apparently not so well understood. The mucous lining of the appendix is subject to and liable to be involved in any inflammatory process occurring in the cæcum, but in the latter organ the healing of a small ulcerated area with the subsequent cicatricial contraction is of no consequence. When there is destruction of mucosa and submucosa in the appendix, the healing results in the formation of cicatricial tissue which must soon produce a certain amount of distortion and narrowing of the lumen of the organ. This state of affairs can only make the ability of the appendix to keep itself clear greater, with a consequent probability of a second attack of the same general character. All who have seen many appendices removed will remember how often the type suggested by this description occurs. There may be several points of narrowing which is of various degrees of development, with almost always a collection of muco-purulent fluid in a more or less distended organ behind the last stricture. The danger of perforation in many of these cases is extreme, for in many of them there has never been any formation of adhesions outside of the appendix. There are, of course, many cases of appendicitis in which the inflammatory process within the appendix is more intense from the first, and there is early local or general gangrene of the organ, with perforation and its various results depending on the conditions in the peritoneum of the iliac fossa at the time. Cases of this kind ought to have prompt surgical attention, so that the amount of necessary surgical work shall be as small as possible, and the danger of general sepsis as remote as we can make it. The idea of waiting for "adhesions to form" or "the abscess to develop" is just as rational as waiting for adhesions in a case of strangulated hernia.

I should like to describe briefly a few cases, all but two of which I have operated upon during the past eighteen months. The others I saw in consultation. I have chosen them because they illustrate some points made in calling attention to the untrustworthiness of the medical statistics of the treatment of appendicitis.

Case I.—Man, aged twenty-one years. He had had several attacks, only one of which compelled him to go to bed. Intervals of about six weeks occurred between the attacks. He came to St. Francis' Hospital for removal of the appendix, if advisable, so that he could go safely on missionary trips. Examination showed that there was tenderness on deep pressure in the iliac fossa, but the appendix could not be felt with certainty. McBurney's intermuscular operation was done, and in ten days the patient was up. There were no adhesions about the appendix, which was freely movable. One inch from its extremity there was an almost impervious stricture, and between this and the extremity the organ was distended with about a drachm of greenish pus. About three-fourths of an inch from the first stricture there was another, not so tight, and between the two there was more pus. A man could hardly carry a more dangerous article than a thin-walled sac of pus suspended in his abdominal cavity, yet medical treatment would have "cured" any attack that this patient had had, and he might thus have enriched several statistical lists before the sac ruptured.

Case II.—Boy, aged fourteen years. He had one sharp attack a number of weeks before admission to St. Francis' Hospital. The boy was in excellent general condition, and was sent to the hospital because his physician believed that an operation was the best treatment for his condition. There was no tenderness, and the appendix could not be felt, as the boy was fat and muscular. The same operation was done as in Case I., and the patient was well in two weeks. The appendix was lying along the postero-internal aspect of the cæcum. It was about three and one-half inches long, and one and a half inches from its extremity there was a sharp angle, so that the organ was doubled with its tip pointing almost directly back to the base. The angle thus formed was tightly adherent to the cæcum, and the rest of the organ was perfectly free. The appendix beyond the angle was tensely filled with muco-pus, and it burst during removal. A small area of granulation tissue remained on the wall of the cæcum where the appendix had adhered, so that a small strip of gauze was left in the wound for four days. This appendix was on the point of rupture when the operation was done, and the boy is certainly better off now than if a four-inch incision had been necessary later with the unavoidable division of muscular tissue.

Case III.—Girl, aged ten years. This case was much like Case I. There had been several attacks, and the child was brought to St. Francis' Hospital for treatment. There was distinct tenderness, but no mass in the fossa. The last attack had occurred about three weeks before operation. The operation was the same as before, and the patient was well in ten days. The appendix was free, and distended toward its tip with fecal pus, and it contained several calculi. There was no actual closure of the canal, but the middle inch was much narrowed and was cicatricial. The last calculus could not pass this area; the others were on the proximal side. This appendix was certain to have behaved badly, and the attacks would undoubtedly have increased in severity.

Case IV.—Woman, aged thirty years. Her history was obtained with difficulty. When brought to St. Francis' Hospital she was evidently recovering from an attack of appendicitis, and as soon as we could get an interpreter a history of other attacks was elicited. Examination showed marked tenderness in the iliac fossa, and the appendix could be felt. This patient's temperature ran pretty regularly to 99.5° or 100° F. at night for several days during which she was under observation, and then the intermuscular operation was done. The woman left the hospital well in two weeks. The appendix was three inches long, free, and contained several calculi and some pus, but there was apparently no stricture. The tip was moderately distended, and the largest calculus was in this locality. Operation was certainly the only way of putting this patient in a safe condition.

Case V.—Well-developed and muscular young woman, aged about twenty-eight years. She gave a history of a number of attacks, most of them mild. She came to St. Francis' Hospital for diagnosis and treatment, although she was not ill at the time. The appendix was distinctly tender, but there were no other local signs. The same operation as before was done, and she was well in two weeks. The condition in the appendix was almost exactly the same as in Case IV., and there was just as little prospect of spontaneous cure.

In addition to these cases, I should like to add a short description of two cases, seen in consultation and operated upon by another surgeon:

Case VI.—Man, aged fifty-three years. He had had five well-marked attacks, but had steadily refused operation. His last attack kept him in bed with an evening temperature from 100° to 102.5° F., and marked tenderness and rigidity with flexion of the right thigh. He refused operation for a number of days, during which all kinds of non-operative means were used to help him, and several times he threatened to get up and go out. His tenderness remained, and the mass which had begun to form became more and more distinct. His fever continued and he began to look septic. At the end of two weeks from the beginning of the attack he consented to operation. This disclosed an abscess surrounded by quite dense adhesions, filled with pus containing necrotic shreds. The appendix was not searched for. Recovery was uneventful. The case of this patient is a good example to use in calling attention to the advantages of the interval operation. As it is now he has a long scar; his appendix could not be safely sought for, and the consequences of this state of affairs are obvious.

Case VII.—Man, aged thirty years. He had one sharp attack in 1898, and had been well until the second attack occurred one year later. It was sudden, marked by intense pain and the usual symptoms of perforation. Operation was performed about twenty-four hours after onset. The appendix was free and perforated. The pelvis was full of turbid fluid, with flakes of fibrin. He was treated with hot surgical salt solution and a drain in the pelvis. Recovery was rapid and uneventful. The appendix was in much the same condition as in Case I., plus the perforation. If this patient had been operated upon in the quiescent period, he would have escaped the comparatively long muscle-dividing incision and the consequent danger of hernia. If this patient had been treated by some medical observers, his first attack would have permitted them to put him in a list of cures.

The figures given by Sahli have been quoted because they are extensive, and because, with some other similar series, they are frequently grouped together. A recent notice of them with others may be found in Boas,[1] in the remarks upon the treatment of perityphlitis. The mortality as mentioned above was given as 8.8 per cent. in the cases treated without operation, but we do not know how many of this 8.8 per cent. were carried through to death without operation, or how many were operated on in a desperate condition after the inefficacy of medical treatment had been shown; though perhaps under the latter circumstances such cases would be made to add to the mortality after operative treatment. It is admitted that in over twenty per cent. of the cases that ended in recovery under medical treatment there were recurrences, but no period of observation is given. This twenty per cent. is probably less than one-quarter of the real figure representing recurrences, and insufficient and inaccurate observation of the subsequent histories of the cases must account for the low figure given. Furthermore, it is important to know how many among even this twenty per cent. come to require surgical treatment, sometimes when it is not available. Periods of a year between attacks of appendicitis are very frequent; two years are a common enough interval, five-year intervals occur, and I have known twelve years to elapse. Medical statistics as usually offered are, therefore, untrustworthy. A twenty-one-per-cent. surgical mortality is entirely too high, and such a series must contain many cases in which timely surgical relief was not afforded. With our present knowledge of the disease, it seems safe to say that one attack of appendicitis makes another almost certain, that medical treatment is useful only as an adjunct and with every preparation ready for a prompt operation, and that operation in the quiescent period is a safe measure, especially because we can leave the abdominal wall strong after it is done. This is a very important consideration for any patient, and for the ordinary workingman it is everything.

In addition to these cases, there were twenty others operated upon by me in various stages of acute appendicitis during the same period of eighteen months in St. Francis' Hospital. All were cases with more or less extensive suppuration and varying degrees of sepsis at the time of operation. Death followed in three cases, and a few words in regard to these may be instructive.

Case I.—Man, aged about thirty-five years, weighing three hundred and ten pounds. He had been ill several days. There was a large mass in the fossa. Temperature was 106° F. at the time of operation, and the patient had diabetes. The mucous membrane of the appendix was gangrenous, and there was turbid fluid in the fossa. Death occurred in twelve hours, with coma and rising temperature.

Case II.—Man, aged twenty-five years. He had been ill four days. His temperature had been between 103° and 104° F. for the period of illness. The abdomen was distended, with great tenderness and marked resistance in the iliac fossa. The appendix was very large and riddled with gangrenous perforations. There were very few limiting adhesions. The patient died rather suddenly at the end of about thirty-six hours. He had some jaundice.

Case III.—Man, aged twenty-one years. He had been ill four days, and came to the hospital. He showed all the clinical appearances of general peritonitis. A large incision was made, with free salt-solution irrigation. The appendix was gangrenous and perforated. Death took place in twenty hours.

At least two of these cases had a very good chance if an operation had been done earlier, for among the seventeen recoveries there were several which seemed clinically almost if not quite as bad. In one of them there was a large secondary abscess of the liver which was operated upon successfully.

INVERSION OF THE UNCUT APPENDIX.

By J. F. BALDWIN, A.M., M.D.,

COLUMBUS, OHIO,

FELLOW OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNÆCOLOGISTS, ETC.

In the issue of the Medical Record of November 25th, Dr. George M. Edebohls presents an exceedingly valuable historical review of the literature of appendicitis. In this article he refers to his method of treating the appendix by inversion, the chief argument in favor of his method being that it obviates the necessity of opening the bowel, with the resultant risk of infection. He states that his procedure, so far as he knows, has found but one imitator, whose first and only case ended fatally. Over against this result, however, he states that in his own hands he has had considerably more than one hundred cases of inversion without a single death.

Some time last year I noticed in some journal a reference merely to a method of treating the appendix by inversion, as advised by Edebohls and Dawbarn. No description was given of the technique of either of these surgeons. The idea impressed me favorably, and I at once adopted it, but devised my own technique. Since the appearance of the article by Dr. Edebohls I have corresponded with him on the subject, and find that my technique is radically different from his.

I have practised inversion in considerably more than one hundred cases; just how many I am not able to state, but I find over eighty in my records for about six months past. I have practised inversion not only in cases in which the operation has been made for appendicitis alone, but also in the great majority of cases in which I have opened the abdomen for any reason whatever. It is now a routine procedure with me to examine the appendix in all such cases, and in practically all I immediately invert it. The exceptional cases are those in which the appendix is found atrophied, or in which the preceding operation has been of such a character as to render it unwise to prolong operative procedures by even the two or three minutes necessary to secure the inversion.

While I have not kept a definite record of all the cases, I am satisfied that I have found a healthy appendix in less than ten per cent. of all abdomens which I have opened. The evidences of disease usually consist in thickening of the appendix, more or less obliteration of its lumen, or adhesions. Occasionally a fecal concretion is found, and not very infrequently evidences of recent acute inflammation, the symptoms of which had been entirely obscured by the greater disease present.

---

[1] "Diagnostik und Therapie der Darmkrankheiten," Theil ii., 1899.

How much of disease, discomfort, and danger have been obviated by this routine removal no one can state. My patients have been uniformly pleased when told afterward that the appendix had been removed. On three occasions I have been obliged to operate for acute appendicitis occurring in cases in which the appendages had been previously removed on account of disease. One of these cases had been operated upon by a distinguished Chicago surgeon, and I had myself operated on the other two. I have now in mind in addition several patients in whom I did not remove the appendix, during previous years, and who are now annoyed at times by a very suggestive tenderness and grumbling in the region of McBurney's point.

The technique of inversion is beautifully simple, and I did the operation very many times, to the delight of visiting surgeons. I did it eight or ten times during the week of the meeting of the American Medical Association, the manœuvre being witnessed on each occasion by quite a number of prominent surgeons. So much satisfaction has been expressed by those who have witnessed these demonstrations, that I am quite certain a number of them have adopted the procedure in their practice.

The appendix is freed from adhesions if present and brought up into view in the usual way. The tip of the appendix is held by my assistant with one hand, while with the thumb and forefinger of the other the colon is supported just below the origin of the appendix. With a ligature carrier a catgut ligature is then introduced at the base of the appendix, so as to include the meso-appendix, care being taken to embrace the small artery that runs along close to the appendix. The meso-appendix is then ligated, the ends of the ligature being left long. With scissors the meso-appendix is severed just beyond the ligature, and the tissues constituting it are then seized either with fingers or forceps and stripped off from the appendix from the base to the tip. This is usually accomplished with a single effort, but occasionally they will have to be removed in pieces. Not infrequently, and quite usually when operating on an acutely inflamed appendix, great thickening of the peritoneal and muscular coats will be found present. These coats will be so infiltrated that inversion is impossible. In such a case a longitudinal incision can be easily made with either knife or scissors, cutting through these two coats down to the mucous membrane. This having been done, the thickened coats are very easily peeled off, leaving merely the mucous membrane intact, which is so thin and soft as to offer slight obstacle to inversion. Not infrequently, however, the distal extremity of this mucous-membrane tube is obliterated as a result of previous inflammatory attacks. In such an event the obliterated end must be snipped off with scissors before proceeding to the next step. Care should be taken, however, not to open into the lumen of the tube.

The appendix having thus been prepared for inversion, the tip is seized between the thumb and forefinger of one hand and inverted by pressing upon it with the blunt end of a patent-eyed needle. The manœuvre is accomplished by a manipulation somewhat similar to that employed in putting a fish-worm on a hook. The tip having been inverted for about the length of the needle, an inch or more, the needle is removed and an ordinary long probe substituted. With this the inversion is completed in an instant. If, as the probe is being introduced into the colon, carrying with it the appendix, it meets with a fold offering obstruction, it should be withdrawn and the rest of the inversion completed with the fingers. This is accomplished without any trouble whatever. Inversion now being complete, one end of the ligature which had been previously used is threaded into the needle and a single stitch taken across the opening in the bowel, which marks the point of disappearance of the inverted appendix. If it seems desirable two stitches can be taken. The catgut is drawn through until the stump of the meso-appendix is brought up against the opening, and then by tying the two ends the operation is completed.

The operation can be usually made in very much less time than it takes to describe it.

The vascular supply is so completely cut off by the ligation of the meso-appendix that I have no doubt the inverted organ promptly sloughs off, or possibly undergoes a species of digestion. I have had but one opportunity of investigating the post-operative appearance of the appendix. In that case death resulted at the end of about a week after the operation; the operation for the removal of the appendix being only incidental, and death occurring not as the result of the operation. The autopsy showed the appendix very much softened and evidently rapidly breaking down. Healing seemed to be complete at the seat of the operation.

In a very few cases in which operation is made for appendicitis, conditions will be found which will render inversion impossible or so difficult as to be unwise. These will be cases usually of gangrene of the tissues, or in which there is a tight constriction near the base of the appendix. Fecal concretions if present can usually be readily forced into the colon, and open the way for more easy inversion.

The only possible objection to the operation is that no specimen is secured to display to the patient and his friends. This objection, however, is of no importance, of course, when considered in connection with the manifest advantages of inversion over opening the bowel.

The operation of inversion is made in a very few moments. There is no hemorrhage connected with it, and there is no danger of infection. When made in connection with other operations requiring opening the abdomen, it can hardly be said to have any mortality whatever. Considering the fact that it removes once for all every possibility of appendicitis in the subject of the operation, and considering the great mortality of the disease which is thus obviated and its enormous morbidity, it seems to me that it would be wise for operators in general to adopt some form of this manœuvre as a routine procedure in connection with their laparotomies.

A CONSIDERATION OF THE FAILURE OF ANTITOXIN IN OPERATIVE CASES OF DIPHTHERITIC CROUP.

By J. EDWARD HERMAN, M.D.,
BROOKLYN, N. Y.

Since the publication of the writer's previous articles in opposition to the serum treatment of disease, the committee on antistreptococcic serum appointed by the American Gynæcological Society reported to the meeting held in Philadelphia, May, 1899: "The outlook for the antitoxin-serum treatment is quite discouraging." Statistics showed the results to be no better, if as good as those obtained without it in the treatment of puerperal fever.

There was a disposition to claim for tetanus antitoxin a very exalted therapeutical value, but recent events have probably convinced most men of its absolute failure. During the past year the obstetrical and gynæcological clinic of the Czech University of Prague had to be closed because tetanus became epidemic, and many of the patients died despite the use of tetanus antitoxin. In the epidemic of tetanus which prevailed last July in New York City antitoxin was generally used, and the disastrous consequence is well known and cannot be denied. The superlative merit of the Baccelli carbolic-acid treatment of this disease was entirely overlooked in the blind craze for serum therapy.

When in 1896 Winters showed the bad effects of diphtheria-antitoxin treatment in the Willard Parker Hospital of New York City, Brannan said he was surprised that Winters should distrust the bacteriological diagnosis as shown by the presence of the Klebs-Loeffler bacillus. That there is no etiological relation between diphtheria and this micro-organism is made clear by the following observations:

Of one hundred cases of chronic nasal catarrh, Vassant by bacteriological investigation found the Klebs-Loeffler bacillus in twenty-six patients, in none of whom was any symptom of diphtheria present.

Grenet and Lesné, in fourteen cases of purulent coryza in children, found a bacillus resembling the Klebs-Loeffler bacillus which in seven instances proved fatal to guinea-pigs and in four produced pseudo-membranes. Yet in none of these children was there membrane present or glandular enlargement.

MacFadyen and Hewlett, after examination of a culture from a swab which was sent to them, reported that the diphtheria bacillus was present. They were then told that the swab had been used on the throat of a pigeon suffering from canker, a disease common on the scalps and in the throats of these birds. The bacillus was also found in the throat of every healthy pigeon examined.

J. Price-Brown reports cases of non-diphtheritic pseudo-membranous rhinitis, which he concludes is as common as primary nasal diphtheria.

Engelmann has seen cases which demanded intubation, although it had not been possible to demonstrate the Klebs-Loeffler bacillus.

Peabody, when called to attend a nurse and being in doubt about the diagnosis, first gave antitoxin and then took a culture, which was negative. At the same time he took cultures from the throats of three children who had been in the company of the nurse the same day. The cultures from two of the children developed the Klebs-Loeffler bacillus, though none of the children ever showed any throat symptoms.

Hennig, in a study of thirty-five cases of clinical diphtheria, of which number only about one-half were infested with the Klebs-Loeffler bacillus according to the report of two eminent bacteriologists, states that the number of cases of post-diphtheritic paralysis was greater in those which did not show the presence of the Klebs-Loeffler bacillus.

In one of the London infectious-disease hospitals there occurred an epidemic of rhinitis in which it was found that the Klebs-Loeffler bacillus was present in every one of the fifty-one cases. In no instance was there membrane in the nose, or glandular enlargement, or fever, or any other indication of disease. In morphological character and by every test known to laboratory workers this micro-organism corresponded to the Klebs-Loeffler bacillus. Todd and Washbourn, who report this epidemic in the London *Lancet*, 1898, p. 1458, say there was no evidence that these cases were the cause of producing diphtheria in people with whom they came in contact.

Soerensen, of Copenhagen, describes a similar experience in the *Zeitschrift für Hygiene*, Bd. 29 u. 31 He found the Klebs-Loeffler bacillus in three hundred and twenty-six scarlet-fever patients during three years, and during the last years by investigation on guinea-pigs the virulence of the germs was demonstrated fifty-eight times in seventy-nine cases. The remarkable thing brought out by this study was the fact that eighty-five per cent. of these convalescents from scarlet fever developed no symptoms of diphtheria. In fifteen per cent. there was membrane in the throat. Of the entire three hundred and twenty-six not one died, if we except the case of a two-year-old weakling whose death was due to pneumonia. The mortality of real clinical diphtheria following scarlet fever is notoriously great. Soerensen's cases were simply bacterial laboratory diphtheria. The good result was not due to the use of antitoxin, for of the whole number of patients only two received injections of serum.

Finally may be mentioned the table in the German collective report, which shows a mortality of 14.9 per cent. in cases positively diagnosed by bacteriological investigation, and 15.8 per cent. mortality in those in which the bacteriological examination was negative.

Dogmatic statements, especially if sanctioned by college teachers, take a very firm hold on the medical mind, but criticisms and corrections do not so easily reach the profession. Though the claim of etiological relationship between diphtheria and the Klebs-Loeffler bacillus has for a long time been shown to be unfounded, the statement that this particular bacterium is the cause of diphtheria is still being made by men who are acquainted with only one side of the question.

So it is with the whole antitoxin theory—the evidence is all against it, but yet it is being taught in the schools as if it were an established scientific fact. To-day the student leaving college has a great deal to unlearn about this matter. If he seek an appointment in the medical department of our army, he will be handicapped in his examination unless he can accept the fantastic vaporings about antitoxin for science; because the question may be, and has been, asked about the treatment of diphtheria—and the bigoted position of the surgeon-general on this subject is well known.

It is an easy thing to suggest a theory, but quite a different matter to force it into the minds of others; especially when you completely fail to fortify it with facts. Even the evolution theory exists only as a hypothesis, and its correctness is still denied by many scientific men of the highest standing. This statement may seem hardly credible to those who had not read much about the matter, but nevertheless it is true. To refer to only a few men who stand as high as any in their own particular lines of work, and who see no convincing proof to sustain the evolution theory, may be mentioned J. William Dawson, late principal of McGill University, who had just died, and Max Müller and Rudolf Virchow. Probably evolution will never be scientifically proved. The writer has read Darwin's work several times with a great deal of interest, but can remember no convincing argument derived from this fascinating study.

When we come to the consideration of the antitoxin theory, we approach a subject which is capable of proof if it contains a germ of truth. But so far nothing has been proved to favor the idea that it is true.

And right here attention will be directed to remind the profession of the dissimilarity between toxin and antitoxin inoculation for the production of immunity.

There is evidence indicating that immunity can be obtained from toxin injection, but there is no proof that immunity has been conferred by antitoxin treatment. There is a widespread tendency to jumble the two things, and claim for antitoxin therapy all the good which has so far been derived from toxin treatment. In a previous article the writer endeavored to make this distinction clear, but in the abstract of this communication in another journal the reviewer made the usual error of confounding the two things by placing vaccination and the Pasteur hydrophobia cure under the head of serum treatment. This same mistake was committed by Fraser before a late meeting of the British Medical Association. He declared that the mortality of diphtheria and hydrophobia had been reduced, and the reader was expected to believe that the decrease in the death rate in both instances is due to the use of antitoxin treatment. Of these two diseases only diphtheria is treated by the antitoxin method. Hydrophobia is subjected to the toxin form of treatment. In antitoxin treatment the serum of another animal is supposed to contain the remedy which is injected into the patient. By this method the attempt has been made to cure diphtheria, tetanus, tuberculosis, typhoid fever, etc., but every effort in this direction has ended in failure. In toxin treatment the serum of another animal is not used, but the patient is directly treated with the disease germ or its product, or some virulent portion of the body of an infected animal. Hydrophobia, sarcoma, and smallpox are diseases which have been successfully treated by this method of toxin inoculation. Antitoxin advocates are sailing under false colors when they appropriate for serum therapy the advantages which have been attained by toxin treatment. We have satisfactory evidence of cures established through toxin treatment; but no convincing proof has ever been presented, either in the laboratory or at the bedside, of any virtue in antitoxin serum treatment.

Tracheotomy in the hands of many operators in the past, before antitoxin and intubation were introduced, gave better results, everything considered, than are now obtained with intubation in connection with the administration of antitoxin. O'Dwyer called himself a disappointed tracheotomist: if he could have saved as many as one case in ten by tracheotomy, he says he would not have turned to intubation. Other men also were unfortunate with tracheotomy, yet that is no reason to condemn the operation utterly, which was only displaced because intubation offers relief in a simpler way in many cases which would not be subjected to tracheotomy until a much later time, because of the horror entertained by most people for the latter operation. Intubation is now performed on very many cases which would never have been given the advantage of tracheotomy. Shaw, like many others, found "it almost impossible to get consent to tracheotomy until the favorable time had passed"; but now, since the improvement in intubation by O'Dwyer, this difficulty has largely been removed.

Pilcher wrote in 1893: "It is difficult to make a proper comparison of results owing to the possibilities of differences in the character of the cases submitted to the two different procedures. It is undeniable that intubation is much more likely to be resorted to in cases of less critical nature than would be tracheotomy."

These considerations should be kept in mind when making comparisons between antitoxin cases of laryngeal stenosis which have been intubated and the results which followed tracheotomy in the past when antitoxin was unknown. It will also be seen that to-day antitoxin-treated cases which require tracheotomy do not give any better results than follow when tracheotomy is performed and antitoxin is not used.

As an indication that a larger proportion of stenotic cases will receive operative aid from intubation, Pilcher states that while in the seventeen years prior to 1893 he had been operating in Brooklyn, and during which time he had been called upon to do tracheotomy in a considerable proportion of the operative cases, he had operated but sixty-six times. On the other hand, during the four years preceding 1893 McNaughton performed intubation one hundred and forty-two times. In a recent letter Dr. Pilcher tells me that tracheotomy is now very rarely called for; and Dr. Fowler informs me that during the past ten years he has done very little, if any, tracheotomy for croup. Pilcher and Fowler believe that antitoxin is largely responsible for the decline in their tracheotomy work. The correct explanation is that intubation has largely displaced tracheotomy. The use of antitoxin has not reduced the relative proportion of operations necessary in cases of diphtheritic croup.

A reference to the compilation of statistics by Maddren and McNaughton in the *Brooklyn Medical Journal*, 1893, makes it clear that operative relief by intubation is now much oftener sought for than was the case when only tracheotomy could be performed for the relief of suffocation. The figures collected by Maddern and McNaughton embraced the experience of about two hundred and fifty medical men with seventy-nine hundred and sixty-three operations. The statistics were founded on the operative work of these men, extending from the beginning of practice up to 1893, and included the six hundred and fifty tracheotomies by Jacobi, whose experience with diphtheria dates back to the middle of this century. The first one hundred intubations by O'Dwyer with eighty-three per cent. mortality were excluded.

We find these operators, during the short time that intubation was available, performed this operation 5,546 times; while the whole number of tracheotomies reported by them, representing their work with the latter operation during their entire practice, amounted to only 2,417 tracheotomies.

Experience of two hundred and fifty operators with tracheotomy and intubation:

Operation.	Time of Experience.	Number of Operations.	Mortality, Per cent.
Tracheotomy . .	Course of entire practice . . .	2,417	75.8
Intubation	A few years.	5,546	69.5

The conclusion has been drawn from these figures that intubation saves six more patients than tracheotomy in every one hundred operations. When it is considered that a vastly greater number of patients are now operated on, and at a more favorable time, by intubation than used to be possible when we had only tracheotomy to suggest, it is probably an underestimate of the present results of operation to say that the difference in favor of intubation is only six in one hundred. While the Maddren-McNaughton statistics include much too small a number of operations to be of final value, yet they unmistakably point to the conclusions above indicated.

That antitoxin has reduced the number of operations is a statement easily made, but not so easily proved. It is often said, about fifty per cent. of laryngeal cases, if antitoxin is injected, result favorably without operation. But the same percentage of recoveries was recorded in five hundred and five cases of croup treated with calomel inhalation, included in the excellent Maddren-McNaughton table—which cases did not receive antitoxin. And yet the American Pediatric Reports state, "Formerly only ten per cent. recovered from croup when cases were not operated upon."

A light dawns on the good antitoxin intubation figures when we read that one man intubated fifty-six cases out of one hundred patients. Another physician, Levy, of Brooklyn, writes to me that he intubated about fifty per cent. of the sixty-three cases he has treated in general practice with antitoxin. Be it understood that these men have not operated on fifty per cent. of laryngeal cases, but on fifty per cent. of all the cases of diphtheria they were called to treat. These men, as would be expected, produce very low mortality figures. So does the man who operates on every case of appendicitis. Intubation by itself, when properly performed and with efficient after-care, ought to be a practically harmless procedure. When fifty per cent. of all cases of diphtheria have to be intubated, one is irresistibly led to think one of two things: either the operation is often done before other means are adopted to cure the patient without mechanical intervention, or else that antitoxin is directly responsible for the aggravation of laryngeal stenosis.

When antitoxin statistics show a small proportion of operations to all cases of diphtheria in general, the explanation probably always is that many cases of bacterially diagnosed diphtheria are included to give the good figures; and the bacterial diagnosis has so often been proved to be a farce that it is becoming wearisome to repeat the fact.

Jacobi has been particularly unfortunate with tracheotomy. Up to 1893 he performed this operation six hundred and fifty times and saved only one hundred and twenty-four patients. Yet in 1893, before the antitoxin-serum chimera had deluded the profession, he was not deprived of all hope, for he then wrote: "Results would now be more favorable; results differ in different seasons." But remember that Jacobi's experience dates back to almost the revival of tracheotomy in this century. It was in 1825 that Bretonneau was made supremely happy by being able to save the life of a dear friend's child with his first successful operation; and in 1852 Jacobi was already studying the disease. He reported a case of diphtheria in New York City in that year, the first case of which the health department contains any record. The statistics of Jacobi's own operations, therefore, embrace the work done by him during a number of different epidemic waves of the disease, which fact should not be lost sight of when comparison is made between his figures and the results of a different operation and a new method of treatment, both extending over only a comparatively few years.

In 1852, Bouchut reported seventy-two per cent. mortality in one hundred and ninety-eight tracheotomies. After that, from 1864 to 1884 there was a mortality of 66⅔ per cent. in the Boston City Hospital. A mortality of 66⅔ per cent. resulted also in Pilcher's private practice from 1876 to 1893 in sixty-six operations. In 1876 the mortality in English and Scotch hospitals and private practice was found to be sixty per cent.

There were three hundred and thirty-three tracheotomies reported in Basle, Switzerland, with fifty-nine per cent. mortality. The reports of Revilliod in 1876 and Sanné, of France, in 1877 give a mortality of fifty-six per cent. in two hundred and fifteen operations.

Since the above-mentioned work was done even better results have followed tracheotomy, as shown in the following table:

TRACHEOTOMY WITHOUT ANTITOXIN.

	Mortality, Per Cent.
Soerensen, Copenhagen, 1895	25
Zurich, 1883–84	40
Drobrink, 176 cases	37
Cohen, 166 cases	33
Strassburg Hospital, 1891	25
Geneva, 1872–88	49
Strassburg, 1891–94	44
London University College, 1884	47
Dower, Brooklyn, 67 cases	25

The figures in the above table give the mortality of tracheotomy without antitoxin treatment. Not only is it impossible to match this table with equally good results with antitoxin-treated tracheotomy cases, but in New York City, Boston, and Philadelphia the much more favorable operation of intubation in connection with antitoxin is followed by a greater mortality than shown in this table of tracheotomy without antitoxin. The following list is useful for comparison:

INTUBATION WITH ANTITOXIN.

	Per Cent.
New York City, Willard Parker Hospital, 9 months, 1895	68
New York City, Willard Parker Hospital, 6 months, 1897	82
Boston City Hospital, 1895–96	53
Philadelphia Municipal Hospital, 1896	56
Philadelphia Municipal Hospital, 1897	68

The next table shows the result obtained by American operators with tracheotomy without antitoxin in three hundred and eighty-seven cases with forty-seven per cent. mortality:

TRACHEOTOMY WITHOUT ANTITOXIN.

	Cases.	Lost.	Mortality, Per Cent.
Boldt, Cocks, and Denhard, New York City	66	31	47
Twenty Brooklyn physicians	238	111	47
Hartwig, Buffalo	3	1	33
O'Shea, Chicago	3	1	33
Townsend, Bergen, N. Y.	13	6	47
Niner and Jennings, Detroit	64	34	53
	387	184	47

The following table contains one hundred tracheotomies without antitoxin by eight Brooklyn physicians, with twenty-eight per cent. mortality:

TRACHEOTOMY WITHOUT ANTITOXIN.

	Operations.	Mortality, Per cent.
Fuller	6	50
Dower	67	25
Maddren	4	50
Spencer	7	29
Phillips	3	
Beach	6	17
Corbally	2	
Stuart	5	60
	100	28

TRACHEOTOMY IN CHILDREN UNDER TWO YEARS OF AGE.

	Cases.	Died.	Mortality, Per Cent.
Without Antitoxin.			
Barzeau	12	8	66
Revilliod	16	10	62
Sonnenberg Hospital, 1896	8	3	37
Total	36	21	41
With Antitoxin.			
London Hospitals, 1896	30	21	70

According to the Maddren-McNaughton idea, that intubation saves six more cases in each one hundred operations than tracheotomy (which was the operation done on the one hundred cases in the above table), had these cases been intubated, the mortality would have been only twenty-three per cent. without the use of antitoxin.

In one of the preceding tables was given the result of tracheotomy without the use of antitoxin, in Denmark, Germany, Switzerland, England, and the United States, all the statistics given showing a mortality of less than fifty per cent. In the next table is shown that such good results have never been achieved with the same operation when the patients at the same time receive antitoxin treatment:

TRACHEOTOMY WITH ANTITOXIN.

	Mortality, Per Cent.
London, Western Hospital, 1896	63
Cassel	61
Baginsky, Berlin	71

Antitoxin advocates would have us believe that it used to be a very rare occurrence for young children to recover after tracheotomy before antitoxin was known. Such, however, is not the fact.

In an article entitled "Is the Operation of Tracheotomy in Diphtheritic Croup Dangerous?" in the MEDICAL RECORD, December 13, 1884, Winters gives a list of ninety-three successful tracheotomies on children two years of age and under. This table contains two, three, four, and in one instance six successful operations by one man. Barzeau saved twenty-five per cent. of twelve cases, and Revilliod thirty-seven per cent. of sixteen cases, by this operation in children under two years of age, to whom no antitoxin was given.

When intubation does not relieve a stenotic patient —which sometimes happens—and the attempt is made to effect a cure with a secondary tracheotomy, it is not surprising that a very high rate of mortality ensues. If antitoxin confers any benefit, it might be reasonable to expect to look for better results in this class of cases which also receive antitoxin than are obtained in patients on whom a secondary tracheotomy is necessary after intubation and to whom no antitoxin is administered. But no such benefit can be claimed in favor of antitoxin-treated cases. For comparison, fifty-six cases requiring tracheotomy after intubation have been taken from the Maddren-McNaughton table, to place beside fifty-six cases which occurred in the Hôpital Trousseau, which latter cases received antitoxin treatment, while those in the Maddren-McNaughton table were not subjected to the serum treatment. In 1897, in the Hôpital Trousseau, fifty-six secondary tracheotomies were performed, and eleven patients recovered. Taking fifty-six tracheotomies from the Maddren-McNaughton table without selection and just in the order as printed, it is found that ten patients recovered. When it is considered that the fifty-six Trousseau patients were all operated on under one roof by specially trained physicians, and watched after treatment by nurses well qualified through constant daily experience with diphtheria patients, while the fifty-six Maddren-McNaughton cases were operated on by twenty-three different operators in twenty-three different places, and aided by such nursing as it is possible to secure in average general practice, this difference of one case in fifty-six in favor of those treated with antitoxin (or less than two per cent. difference), cannot be considered an indication that better results followed in those treated with serum. Absolutely no superiority can be claimed for antitoxin from this experience; all the advantages as regards treatment and after-care were on the side of those treated with antitoxin. As the ages of the patients were not given in either table, it is impossible to consider this important factor, without which the figures given are really without value.

In a previous article mention was made of an experiment which was tried in Trieste by the physicians of that city, who in 1895 treated practically all cases of diphtheria in general with antitoxin. The result was that more patients died in that year than ever before. Kassowitz called Baginsky's attention to this fact, and in reply Baginsky contented himself by saying he didn't know anything about the circumstance. It seems as if some optical perversion prevents him from seeing that which he does not want to see. When the foolish ostrich shoves his head in the sand to cover his eyes, that act does not mislead or extinguish his pursuer any more than this evasive answer deceives the profession or removes the above-mentioned fact.

1098 Bushwick Avenue.

Treatment of Poisoning by Carbolic Acid.—Hypodermic injections of ether. Rectal injections of sodium sulphate, two ounces to three pints of water; irrigate as high as possible after the method of Cantani. Give an ounce of the same drug in a quart of warm water per os, or by means of a stomach tube. If necessary perform venesection, followed by hypodermoclysis or intravenous transfusion of a quart of decinormal saline solution. Give morphine and apply heat to the extremities. If the rectal injection has returned, inject a quantity of a strong infusion of black coffee.—Landouzy.

A COMMON CASE AND ITS PRACTICAL SUGGESTIONS.[1]

By JOSEPHINE M. WETMORE, M.D.,
GRINNELL, IOWA.

When our president requested me to present before this society a paper, or report a case, I looked about, as we all do, for some object of interest occurring in our practice, or pertaining to a subject in which others would be interested; when my attention was arrested by the visit of a patient who came to report progress.

This patient is a type of a large class of cases that are so common and so unsatisfactory to treat, unless the cause of their indisposition can be ferreted out and removed, as rather to weary the busy physician. And because of long-continued symptoms, that are seldom alarming, the case is apt to be catalogued chronic, and is not thought deserving of much valuable time and attention. It is to this class of cases that I wish to call special attention, and endeavor to relieve if possible one great element so conducive and active in their etiology.

This patient came to me some time ago, in the person of a bright, intelligent, rapidly growing boy of fifteen years. His father, dying some years ago of acute stomach trouble, was never strong, was extremely nervous, restless, irritable, and ambitious. His mother, who accompanied him, is of more than ordinary intelligence, education, and refinement. This, the youngest of her three children, all boys, is the most difficult to manage. His restless, uneasy manner, manifested particularly in the schoolroom, has caused him previous to the present term to consider his instructors his greatest enemies. He refuses to apply himself to his studies, to the preparation of which he is expected to devote the waking and some of the necessary sleeping hours. He therefore lives in an atmosphere of discontent and forced depression, most of the time at variance with all his surroundings.

As he sat in the consulting-room, and I tried to secure a full and complete history of his case, he was in constant motion. His capricious appetite is allowed its unnatural demands. He feels tired, is pale and thin in flesh, the bowels are sluggish, the breath is offensive, the tongue is coated, and the gums are spongy. He has a dull headache, and the two symptoms of which he complains the most, and has complained for two years, and for which his mother requests relief, are pain around his heart and dyspnœa. These two symptoms have of late given himself and mother much uneasiness; heretofore they had ascribed them to his rapid growth. By pressure over the point of exit of the spinal nerves this pain is greatly aggravated. There are also several points of hyperæsthesia along the spinal column. A thorough physical examination and careful questioning as to bad personal habits, the latter of which are denied, reveal no organic trouble of any kind. A rapid, slightly irregular heart action and diminished lung capacity are the only signs present.

What shall I do for this patient? Shall I insist upon uninterrupted confinement in the schoolroom, prescribe some nerve sedative, or stimulant, and lull for time at least these crying needs? He is from a family financially independent of any physical exertion or denial of any reasonable wish. He has only to occupy himself with that which will educate and refine him. He has ambitions in a mechanical line, enjoys employment with tools, and is naturally a mechanical genius, but has been rather discouraged, or at least not encouraged, by his mother, who would have him a scholar, with no thought of his health to interfere with her ideal plan. It was with much difficulty and after continued reasoning that I persuaded this mother to relax her ambition and take the boy out of school. I then laid out a plan of work, exercise, and rest; he was to rise at 6 A.M. instead of 8:30, take his cool sponge bath, with his mother's assistance until accustomed to it, have a little exercise, and partake of a plain, nutritious breakfast. During the meal he should form the habit of eating slowly and thoroughly masticating his food; then take exercise, in which he should accomplish a definite amount of work. He should attend school. recite one lesson during the forenoon, have his heavy meal at noon-time, afterward rest in the recumbent position one hour, sleeping if possible; recite another lesson in the afternoon, studying for a sufficient length of time to prepare these two lessons; he should have recreation and work of a proper kind, and retire at 8 P.M. In fact, he was to live like a child and not a young man. His only medicine after cleansing and disinfecting the gastro-intestinal tract was, along with continuous use of astringent disinfectants for the mouth and teeth:

---

[1] Read before the annual meeting of the Iowa Central State Medical Society.

℞	Blaud's mass	gr. iij.
	Soc. aloes	gr. $\frac{1}{8}$
	Ext. nux vom	gr. $\frac{1}{16}$
	Arsenious acid	gr. $\frac{1}{100}$

It is needless to tell you the results of this plan of treatment. The relief from constant attendance to school duties stimulated his ambition in his studies, the change being quickly recognized by his teacher, who had exercised great patience and forbearance, and understood the great strain under which her pupil labored with this enforced education.

This rather lengthy description of a very common case fits many others which have come under my observation, not only boys, but more frequently girls, ranging in age from twelve to sixteen years. At this age ordinarily they reach a grade in school where they are obliged to devote their entire time until nine and ten o'clock at night, Saturday included, bending over their books, applying themselves as diligently as the mature adult student who is taking up a profession, with only a thought of high grades at whatever expense to the physical health.

At this very important developmental age, functions heretofore unknown are asserting themselves, and rightly demand the best and purest blood for the proper growth and development of the organs concerned in these functions—blood rich in oxygen, unburdened by vitiated air and poisons of gastro-intestinal origin, blood that flows freely with the assistance of well-developed muscles that are growing strong by sufficient physical exercise. Perhaps now, more than at any other time in life, should the activity of the unstable nervous system be kept in abeyance. As far as the child is concerned it should not know that it has nerves, but how often is such a one brought to us because of extreme nervousness!

In the girl, particularly at this age, the most important organs of her body, so far as her future health and happiness and that of her offspring are concerned, are coming to the front and eagerly demanding their rightful supply of nutrition. The languor and indisposition for mental exertion are only mute messengers to us requesting precedence for reproductive development. Our present system of education completely reverses the natural law, and our young girls about to become women are made to suffer untold agonies, mortifications, and heartaches the remainder of their lives through dysmenorrhœa, the torture of which can be second only to the pangs of parturition, and must be experienced twelve times each year with ofttimes no relief excepting of an operative nature, and even this is followed by other as distressing and incapacitating ailments.

The lack of proper and sufficient exercise during this period may well cause a debility of muscles and ligaments, whose function it is to support; this in turn allows flexions, versions, prolapsus of uterus and ovaries; the insufficiently supported blood-vessels allow a varicosity or perchance menorrhagia, or amenorrhœa, coupled with which are neuralgic horrors of various degrees and regularities. And this is not all; but constipation adds its quota to the already overburdened system; the patient suffers from frequent headaches, insomnia, and that stigma of Americans, nervousness, with all that follows in its wake.

The young girl, with more sad experiences than her great-grandmother ever dreamed of, reaches a crippled womanhood. Ofttimes she has been a regular attendant on the gynæcologist. If perchance she engages in public work, she must absent herself from work from one to four days, and suffer all the attendant mortification and embarrassment in proportion to her womanly modesty. In fully seventy-five per cent.—and I think I am not overestimating—she must seek the gynæcologist's assistance sooner or later, and not infrequently be brought to death's door reaching the crown of her womanhood—maternity.

Should we not as physicians and guardians of the public health use our influence to prevent, in so far as preventable, causes which strike at the heart of physical health?

I believe that when the physical development of womankind—and by this I do not refer to the gymnasium, bicycle, or tennis courts—is put in the ascendancy during her period of special development, we shall have reached the millennium in health both of men and women. Of course we cannot expect all the results in the next two generations, nor will such a reform probably eradicate all deformities. Every girl should have work during this period of partial mental suspension; she should under no circumstances be allowed to idle away her time, do fancy work, read light, trifling novels, or attend parties, balls, etc. There is no better time in her life than now to put her at work which is often considered undignified, viz., housework. There is no work in gymnasiums, cooking-schools, etc., equal to everyday dutiessu pervised by a thrifty, intelligent mother. It is not drudgery. but is elevating and broadening; the very precision used in the artistic arrangement of table or china closet, the preservation and proper preparation of plain articles of food, economically handled, can be made of far greater value in the future welfare and happiness of mankind in general than all the trigonometry and astronomy known. Do not understand me to deprecate the higher and college education of our women—far from it; I only plead your attention to the more perfect physical development during this important period.

When nature has well established her higher task, there is plenty of time for further mental education, which has been held in check for a time only. No more unreasonable is it to tear open the beautiful bud to see its beauty and hope to enjoy its fragrance, before nature is ready, than to crowd a young creature beyond the limits imposed by this common law. The results are comparatively as disastrous in the one as in the other. In the great struggle for education and mental attainments, the suitability of such crowding and over-encouragement to young minds, aside from the effect upon health, is overlooked. Not every pupil will make a scholar; some who are educated at great expense and sacrifice for the learned professions would achieve far greater success and happiness following the plough.

Because our neighbor's boys and girls are brilliant professional workers is no reason that our children should follow in their footsteps. Ofttimes the ambition for the child overcomes the better judgment of the parent, and a life-work from which the young man feels ashamed to turn back is entered upon, and his discontent finds its only relief in pleasures that degrade rather than elevate. It seems to me that this period of lessened mental strain might be one in which a child could show its natural capabilities.

What I have said applies equally to both boy and girl; the higher education should be secondary to the physical. Neurasthenia, in its various degrees, is our prevalent condition. Why is it so? Is there not a close relation between our developing young and our adult neurasthenic? Where is the trouble, and who is at fault?

But, many will say, we are not consulted in regard to these cases until they are practically incurable. They mistake; they do not recognize the necessity for a careful examination and diagnosis in the little patient who is brought, complaining of headache, backache, or stomach-ache, and is so tired, and, the mother explains, so nervous, but accept too readily the diagnosis so unhesitatingly offered, of some stomach trouble, eye-strain, or worms; treatment for either of which will result in a slight improvement for a time at least, and the case is discharged, probably with satisfaction to the mother, but it should not be so to the physician.

A few years later he may be called to care for a nervous wreck which might have been prevented had sufficient time and attention been given years before.

When we physicians take time from our busy lives carefully to diagnosticate these cases, and to lay out a plan of treatment which shall include exercise and rest, and do it definitely, with as much precision and insistence of its importance upon our patient as we prescribe arsenic, strychnine, etc., this being coupled with this judicious administration of a little medicine as indicated, we shall be spared the anxiety that will come to us while attending these same children, older grown, through some acute disease when we know their nervous resistance to be low.

When we have done our duty in these seemingly minor details, then and then only may we hope truly to benefit humanity, which is the ambition of every worthy physician. We ask pardon for using the time allotted for other than scientific technicalities, for not relating some very unusual case, instead of calling your attention to a subject which, if recognized and attended to, means far more to humanity at large than many severe and interesting operations. This is a matter that confronts every general practitioner, perhaps every day of his life, and upon his intelligent appreciation and management a large amount of the good he does depends. Our patients come to us for advice far oftener than for medicine or the knife. They are well informed regarding foreign topics, politics, and war problems; but how helplessly ignorant of the proper care of themselves they are only the doctor knows.

I do not advise closing up our public schools, but I do advise modifying and arranging the work of our boys and girls at the age of puberty, that they be confined in the schoolroom a much shorter time than now, that studying out of regular school hours be entirely prohibited, that during their time spent outside of the schoolroom they be systematically employed at occupations that shall rest and refresh and fit them for future life-work. They must not be idle.

Their occupations should bring into play all parts of their growing bodies, give them healthful exercise and fresh air, work as unlike their studies as is possible, that they may during this period be allowed to cultivate natural ambitions, unhampered by over-zealous parents and teachers, who are to temper and correct, hold in abeyance rather than over-stimulate. Some pupils will stand more crowding in mental work than others; each one is a law unto himself. We cannot lay down hard-and-fast rules for the school to go by; we cannot look to the school board, superintendents, or teachers for this help, for the direction of such matters is entirely within the province of the family physician, and the accomplishment will be obtained with the co-operation of the parents whom we now educate for the coming generations.

After the functions of the adult being are thoroughly established, then may our student take up higher studies and find himself able to accomplish much without detriment to his physical body or mental capacity.

Undoubtedly this nervous strain causes many a young and promising woman to lose her ambition and gradually drift into semi-invalidism because she feels incapable of keeping up with the demands made upon her; the pity and compassion of over-sympathetic friends magnify and intensify her symptoms until she easily resigns herself a martyr to her feelings. Not even the physician or sensible friends can persuade her otherwise; not until some actual necessity arises by which she is obliged to forget herself and unconsciously accomplish a reasonable amount of work does she awaken to her possibilities, and her invalidism becomes a thing of the past.

In conclusion, does it not seem reasonable to believe that by a proper direction of the education of our young at puberty, they will be better able to withstand the great strain incident upon any line of work? May we not in a great measure prevent these complete wrecks, which the physician is expected to endow with life and ambition, and in which in so far as he is successful is his professional ability estimated by the laity?

GYNÆCOLOGY AND GYNÆCOLOGISTS IN EUROPE.[1]

By ABRAM BROTHERS, B.S., M.D.,

NEW YORK,

ADJUNCT PROFESSOR OF GYNÆCOLOGY AT THE NEW YORK POST-GRADUATE HOSPITAL; VISITING GYNÆCOLOGIST TO BETH ISRAEL HOSPITAL, ETC.

In the present communication I purpose to describe some of my experiences in the clinics and hospitals of Berlin, Paris, and London during the two months dating from September 20 to November 15, 1899. As my object in going abroad was primarily for rest, the scientific work was necessarily limited and followed up rather in the sense of diversion than active work. But for the physician abroad in pursuit of pure scientific knowledge, it is wonderful how much can be accomplished in the short space of two months.

Although I was fully armed with letters of introduction, I wish to state at the outset that they are not essential, and that the ordinary visiting-card will serve all practical purposes. A knowledge of French and German is necessary, however, for immediate and rapid work, otherwise the visitor may flounder about for months accomplishing very little.

As at home, very little is done abroad during the summer months. In Berlin a special preliminary course of instruction is given by "Privat-Docenten" toward the end of September and beginning of October. Some of the professors take part in these courses. In France and England very little will be seen before November.

Naturally my chief interest was centred in gynæcology and surgery, although from time to time I trespassed upon other branches of medicine.

At Berlin, the best location for the medical visitor is the neighborhood of the Friedrichstrasse Bahnhof, which is centrally located and within walking distance of the principal hospitals and clinics. It is well to call at the Langenbeck-Haus (5-9 Ziegelstrasse) and make inquiries of the secretary regarding the courses one chooses to take. In order to be admitted to the operating-rooms it is customary for the visitor first to call on an operator and present his card. With the exception of Olshausen I found the operators very cordial during one or two visits, after which it was made painfully clear that, in the absence of "taking the course," such visits would be cheerfully excused.

---

[1] Read at a meeting of the Eastern Medical Society, held December 8, 1899.

Olshausen is the chief of the Universitäts-Frauenklinik(at 20 Artillerie-Strasse). He is a man of about sixty-five years, with full gray whiskers and thin hair. His face is wrinkled and puffed under the eyes. His sight is good and he works without glasses. He has the best record for Cæsarean section. His methods are precise. Everything about him has an air of quiet dignity, and nothing in the course of an operation seems to disturb the gentleness and serenity of his disposition. He talks very little, and that in a quietly subdued tone of voice. He works with wonderful rapidity, helping himself to his own instruments from a little tray at his elbow. I saw him remove an immense ovarian tumor, and close up the abdominal wound in three layers of sutures, within fifteen minutes. He works in a small room, and the visitors are requested to leave at the end of each operation. Although my notes are very copious, I shall content myself by stating that I saw Olshausen do quite a number of major operations—laparotomies for different tumors and hysterectomies. I saw him do his first Alexander operation, and, although working more slowly than usual, he succeeded in finding the ligaments. He very seldom resorts to drainage or flushing of the peritoneal cavity (relying on gentle wiping with gauze), and closes the abdominal wall in tiers (three or four) of sutures. He uses catgut exclusively. After the wound is sewed, he dusts the line of approximation with powdered bismuth and seals it with gauze and collodion. He does not rely on clamps for permanent hæmostasis, but uses ligatures. One assistant gives chloroform. His house surgeon simply holds retractors; one nurse threads needles, and almost everything else down to applying the bandage he does himself. I fear, however, that he is a little ultra-conservative, and I have seen him leave diseased tissues which most operators would have removed. In hysterectomies (abdominal) he leaves the cervix in all cases, although he confessed that recently one of the women in his wards had succumbed to secondary carcinoma developed in such a stump.

Koblanck assumes full charge in the absence of Olshausen. He is a thin-built individual of about thirty-five years, with dark sandy hair and whiskers, the latter trimmed to a point. I saw him do a laparotomy for a intraligamentary ovarian cyst which was adherent to the anterior peritoneal wall, small intestine, and mesentery. Although a very difficult case, he handled it like a master. In a second operation for prolapsus uteri the vagina was narrowed by plastic work, and then the uterus ventro-fixated by wormgut and catgut passed simultaneously in the eye of one needle. In this case, as in several other chloroform cases which I witnessed, the patient almost succumbed to the narcosis. Olshausen frequently enters the operating-room when the younger men are at work, and does not hesitate to criticise and reprove them when he finds the technique faulty. In one case of perineorrhaphy he obliged the operator to remove his sutures because the vagina was too much contracted.

Gebhard, the pathologist to the Universitäts-Frauenklinik, is a remarkable individual. He is under forty, combs his hair (which is jet black) à la Pompadour, and has a thickly scarred face, adorned with a little mustache. He is equally at home at the operating-table and in the pathological laboratory—a most unusual state of affairs for a German clinic. He has written recently a most excellent book on gynæcological histology. When I asked him how long it took him to write it, he quietly replied: "Two years for the writing, and all of my medical life for the preparatory work."

Landau's private hospital is located at 21 Phillipstrasse. The chief of the clinic is Leopold Landau. He is assisted in its management by his brother Theodore. The house surgeon is Thumim; and Pick is in charge of the laboratory. The medical visitor to Berlin must not fail to call at this little hospital (which is a model of its kind). Under Pick, I spent nearly four weeks almost daily in the laboratory, preparing, staining, and mounting specimens. Pick has discovered a method of preserving the natural color of tissues indefinitely. There are hundreds of jars in the laboratory containing specimens of gynæcological pathology. The system followed is ideal. After operation the specimen is sent up to the laboratory, where it is placed in a jar and labelled. A gross report is added to the clinical history and description of the operation. Slides are mounted with sections for microscopical study, and the result is added to the former notes. These slides are preserved in special cases where they are carefully numbered and labelled; so that, in any given case, not only are the histories available, but the gross and microscopical specimens are ready for immediate consultation.

The Nitze and Casper methods of examining the bladder are almost universally employed in Germany, and I determined to master the subject. I found Thumim giving instruction in this field, and took a course with him. After six or seven sessions, working on a model and on a number of women, I felt quite at ease in the use of the cystoscope and ureteral catheter.

Leopold Landau seems to be a man aged nearly fifty, with full beard trimmed to a point and progressive baldness beginning at the back of the head. I saw him operate on three occasions: three vaginal hysterectomies, one abdominal hysterectomy, and several laparotomies. He is extremely radical in his work, and in my presence he stated that he had already done eight hundred and thirty hysterectomies. He frequently removes two or three uteri in the course of a morning's operations. He takes no stock in leaving a portion of an ovary to prevent the sudden onset of the menopause. I shall not enter into the details of his methods of operating beyond stating that he is one of the chief exponents in Germany of the clamp method in hysterectomy. His last one hundred and twenty or more cases have been done with the Thumim angiotribe (which is a modification of the instrument devised by the French surgeon, Tuffier). As a matter of fact, I witnessed the successful employment of the instrument in the hysterectomies done in my presence. The abdominal hysterectomy was done after the method published by Doyen, but Landau said that the operation was original with himself. Excepting the first inspiration from Péan, he claimed originality for all his technique, as far as the French were concerned, in connection with hysterectomy. Be that as it may, he is one of the best operators in the world. I will simply add that he rapidly closes his abdominal wounds after laparotomy with one row of silver-wire sutures.

Dührssen's "Privat Heil-Anstalt" is an old private residence converted into a hospital, and is situated at N. W. Schiffbauerdamm 31. He is a tall, handsomely built man of forty-five, with blond mustache and short cheek-stubs. I saw him do a vaginal hysterectomy with a new ligature material known as 'Celluitzwern." The patient was a spinster, aged fifty years, who had once suffered from gonorrhœa, and recently had been troubled with excessive hemorrhages due to a soft submucous fibroma. As an operator, I consider Dührssen slow and painstaking. He seemed to be exceedingly irritable toward his assistants. Like Landau and Olshausen he employs a nurse to thread needles and hand instruments. Two assistants are at the wound, and a third gives the anæsthetic. I noticed a Snegireff vaporizer in the room, which Dührssen told me had done him good service in a number of cases of uterine hemorrhages.

Mackenrodt has a private hospital at Johannisstrasse 10. He looks to be about forty-five, and has reddish pointed chin-whiskers. He was courteous enough to send me an invitation to an operation which I was unfortunately unable to attend.

I saw Gusserow do several vaginal operations for diseased adnexa at the Charité (13 Luisenstrasse). He is a stout, thick-necked, thin-haired, plethoric individual of sixty, with a heavy dirty-gray mustache. He is very rough toward his assistants, and has a very uninviting appearance. I did not talk to him, having been warned that he sometimes treats his visitors rather discourteously.

Martin is no longer at Berlin, but his former private clinic is under the management of Orthmann, who made me feel good by telling me that he had read my name in the medical journals, particularly in connection with the proceedings of the Obstetrical Society. He is a heavy, stout person with blond whiskers trimmed to a point, who sweats profusely and incessantly while operating. I saw him do a laparotomy for tuberculous adnexal disease, and after two hours' work when I left he was just beginning to close up the abdominal wound.

König, Jr., is the first assistant to v. Bergmann. He is an exceedingly modest but able surgeon. Under his supervision I enjoyed the privilege of rehearsing quite a number of intra-abdominal operations on the cadaver and on living dogs.

Besides my work in gynæcology I made single visits to various places. Thus, I was invited by Nagel to attend his class when he was teaching the various gynæcological operations on formalin-preserved genitals removed from cadavers and sewed into obstetric phantoms. I visited Virchow's museum and saw some of the famous specimens which have been collected by the master during a half-century.

One day I called at Rosenheim's polyclinic, where clinical instruction is given in the disorders of digestion. It is a filthy set of apartments situated in an upper story of a rear building. The dust in places was quite thick. Rosenheim himself, however, is a very clever diagnostician, and I think his course can be taken with advantage by visitors interested in general medicine.

At the Charité, König, Sr., was operating for the benefit of military surgeons, and at the Kaiserliche Krankenhaus I saw quite a number of the younger men do all sorts of general surgery. Some mornings three operations were being done simultaneously in the one operating-room.

Altogether, I am satisfied that at Berlin a great deal of good work can be done by the medical visitor in every branch of medicine and surgery. Unfortunately the work is scattered and quite expensive. One morning I visited at the large public Kaiserliche Krankenhaus the surgical clinic of a young surgeon named Lexer in company with two American colleagues, and he actually sent the janitor up to us to find out if we had taken tickets for the "course."

There are a good many foreign physicians studying in Berlin—Russians, Turks, Japanese, Belgians, and Americans The last variety is rated very low. One Privat-Docent told me that the American physician had very little standing, unless he was a graduate of Johns Hopkins, Harvard, Yale, or Princeton. He thought that Columbia was beginning to assert herself —which was a slight relief to me.

At Paris, I could see no evidence of a systematic course of instruction for foreign graduates in medicine as we understand this in America. Unfortunately for the visitor interested in gynæcology, all the operators in Paris have selected the same three mornings in the week (Tuesday, Thursday, and Saturday), at the same hour in the morning (10 A.M.), for performing operations. The consequent waste of time (in case one of them fails to operate) can readily be understood.

It is necessary to speak French at these clinics. Only a few of the Parisian operators (notably Pozzi) speak English. Even broken French is better than nothing, for the Frenchman is much more charitable toward the foreigner speaking the language imperfectly than his German colleague. Again, the sense of constraint in the atmosphere of the German clinics is entirely absent in the French hospitals. The visiting surgeon often enters the operating-room with a cigarette in his mouth. The signs on the walls of the German operating-room, "Favete linguis" and "Noli tangere," do not haunt the visitor in France. The visitor is usually invited to a seat at the back of the operator's chair. In Germany also he is permitted to stand close to the operator. In England he is placed behind a railing at a distance. In France, as well as in Germany, the visitor is given a linen coat—excepting at Landau's clinic, where the visitor simply removes his coat. In England these precautions are regarded as superfluous.

With the exception of a few like Pozzi, the French gynæcologists prefer to be called surgeons; and, as a matter of fact, many of them do all sorts of general surgery. This is notably true of Doyen and Tuffier. Pozzi, being a senator, seems to have a mighty "pull," for the government has erected the magnificent "Annexe Pascal" at l'Hôpital Broca (111 Rue Broca), where a pure gynæcological service is maintained. The walls are decorated with beautiful oil paintings, which must have a happy and cheering effect on the patients as they gaze at them from their beds. These walls are regularly scrubbed as if the paintings were not present. There are two operating-rooms, of which one is reserved for purely aseptic operations. Every modern arrangement for ventilation, heating, plumbing, etc., will be seen here. The largest sterilizing apparatus in the world will be found in one special room. The out-patient department is isolated from the hospital proper, and on one of the walls I read the notice, "Never introduce the sound without first inquiring as to the date of the last menstruation"—a very suggestive recommendation.

Pozzi is a dark-haired, swarthy-complexioned man with black whiskers, tinged with gray and carefully trimmed to a point. His nose is somewhat aquiline, his forehead recedes, and he wears a skull cap while in the hospital. I met him a number of times on the street, dressed in the height of fashion and presenting a scrupulously elegant appearance in his tall silk hat and snugly fitting, long English overcoat. Although present during operations by his assistants, I failed during these visits to catch the master himself at work.

I saw Ségond operate at La Salpétrière, which is situated on the Boulevard de l'Hôpital on the other side of the Seine. It is the largest hospital I ever visited, although I am told that it is smaller than the Vienna hospital. It accommodates nearly four thousand patients. Imagine a town enclosed in four stone walls and containing many dozens of stone buildings separated by lanes, streets, and large courts.

Most of these buildings, or "pavillons," are wards for patients, and have been named after the famous men of France. They are usually two or three stories high. In other buildings are housed the engineer, the machinist, the blacksmith, the barrel-maker, the laundry, the kitchen, etc. Under a large shed quite a number of ambulances and hospital wagons were seen. Opposite was the barn with a few horses. Then there were different kinds of stores in which fruits, vegetables, and tobacco were exposed for sale. In some of the oldest buildings (probably four centuries old) which seemed to present a dilapidated, crumbling appearance, signs of "To Let" were visible in the windows. They were probably intended for hospital internes residing on the premises. Of course the usual chapel was present and occupied a building for itself. It faced the beautiful, large, tree-lined main entrance or main court. Several groups of fine old statuary occupied the hall of the central building, and just to one side of the outside entrance gate was the statue of Charcot recently presented by the friends and disciples of the master who has made the Salpêtrière famous throughout the civilized world.

The grounds of this hospital are so large that it has been found necessary to lay tracks over which small wagons with their loads of food or clothing are pushed by women. A quaint sight is that of women, in the open courts, washing linen and underwear on stone slabs with soap, water, and scrub-brushes; then rinsing in little tubs and placing the wash on the grass to dry. It is the same picture that one sees below the surface of the street in the little compartments along the borders of the Seine, where sometimes a dozen women can be seen washing in this antiquated fashion.

Although La Salpêtrière is ancient and crumbling, and far behind our ideas of a modern hospital, one cannot avoid a sensation of pleasure at the air of quaint neatness and cleanliness which everywhere prevails. One sees the picturesque atmosphere of centuries ago, handed down in all its primeval freshness. The contrast with the rest of Paris (which is so glaringly modern in everything else) is so sharp that one certainly misses a most interesting feature of internal Paris in failing to visit La Salpêtrière.

Ségond is a man of fifty, with waxy complexion and gray color to the hair, mustache, and chin-stub. He is an incessant cigarette smoker. He operates on a table which he brought back from his recent visit to New York. He is pushing the American method of abdominal hysterectomy. I saw him do three vaginal hysterectomies with clamps, besides a number of smaller operations. When I called his attention to the fact that one of the hysterectomies took just five minutes by my watch, he replied: "That's nothing, *mon enfant;* on my prize-days (*jours de fête*) I do them in three minutes."

Tuffier is a slim individual, nearing forty, with black mustache and whiskers trimmed to a point. He has the dark complexion and tendency to wrinkles so noticeable among the French. Unlike Ségond, who is constantly cracking jokes during operations, he is very quiet and serious while at work. He does most of his operating at the Hôpital Lariboissière, on the Boulevard de la Chapelle, and named after a countess who left her entire fortune to the state. I saw him do quite a number of operations: an abdominal hysterectomy (by the Howard Kelly method), several laparotomies for tumors of the ovaries and ectopic gestation, and a transperitoneal nephrectomy for an unrecognized cystic kidney. He drains most of his abdominal cases with a specially constructed metal drainage tube. He also does general surgery. Thus he tried to remove a bullet from the hard palate of a case of attempted suicide; and he showed me a successful case of gastro-enterostomy. He is the inventor of the angiotribe (which, by the way, Doyen denies), and he applied it in one case in my presence. I noticed that after sufficient tightening of the screw he immediately removed the instrument from the broad ligament, and all bleeding was controlled. He ridiculed Thumim's claim of having discovered any improvement on his instrument. Just the same, however, he does most of his operations with hæmostatic forceps and ligatures.

I cannot help alluding to a little building on the Boulevard de Clichy, at which Tuffier also operates, and which is known as the "Dispensaire Gratuité." It was constructed from the private funds of a marchioness, and is managed by the same lady, who resides in the little institution. Although accommodating only six patients, it controls an immense outdoor service among the poor of the neighborhood. The neatness and simplicity of everything in the place are exquisite. The plain wooden operating-table, Tuffier told me, cost just $5; and all the other furnishing in the operating-room, including sterilizers, vessels, tables, chairs, etc., cost just $20 more. And Tuffier does hysterectomies, gastro-enterostomies, and all sorts of major operations in this cheaply fitted operating-room, with brilliant results. There was one ornament in this little operating-room. evidently placed there through the religious zeal of the estimable lady in charge. On one of the window-sills (but excluded from the room proper by the intervention of a thick plate of glass) could be seen a little group of plaster casts in colors representing the Virgin and Child with two kneeling angels.

Le Dentu mixes a little gynæcology with much general surgery at the Hôpital Necker. He is one of the best "all-round" men I ever saw. He is over fifty, has gray hair and whiskers, and wears glasses. Besides several general surgical operations I witnessed the removal of a large suppurating intraligamentary cyst. Most operators, under the circumstances, would have contented themselves with simply evacuating the liquid and sewing the sac into the abdominal wound. Le Dentu, however, separated the tumor from surrounding adhesions, taking painfully close chances of seriously injuring the intestine, and finally succeeded in completely enucleating the sac.

I saw Richelot at the Hôpital St. Louis—one of the oldest and largest of the Paris hospitals, and known to Americans chiefly because Fournier (the eminent syphilographer) is on the visiting staff. Richelot is under fifty, and has the index finger of one hand completely ankylosed after a surgical injury, and which he told me caused him no difficulty in his work. His beard was closely trimmed and quite gray. He was very cordial, and invited me to be present during the ensuing week, when he proposed doing a hysterectomy. As I left Paris several days later I was unable to take advantage of this invitation. He did a small operation in my presence. After locating a vesico-vaginal fistula by injecting the bladder with milk, he touched its edges with the Paquelin cautery. The fistula was the disagreeable sequel of a vaginal hysterectomy which he had done several weeks previously.

Reclus, whom I met at the Hôpital Laennec, is a small, wiry man over fifty, with grayish beard and a very high forehead. Contrary to the custom of most of his fellow-colleagues, he arrives punctually at the hospital each morning at nine o'clock, where he meets a dozen to twenty students and visitors, who follow him from bed to bed. He is an exceedingly clever diagnostician, and one of the best teachers I ever listened to. Without any ado, he picks out a man from the surrounding group, and, giving him a patient, makes him explain every step in the process of reasoning, essential to a correct diagnosis. At my first visit I was a little nonplussed at being requested to examine several patients, and express an opinion. This was not at all very agreeable with my imperfect French in the presence of a large class—especially as he did not hesitate to criticise my views. But altogether he is such an amiable person that I shall always recall with pleasurable feelings my three or four visits to his clinics. At one of these he did an interval operation for appendicitis, but was unfortunate in losing the patient. As luck would have it, the case was one in which we were opposed as to the advisability of operating just at that time.

The sessions of the Congress of the French surgeons were held while I was in Paris. Among other things I remember that Championnière advocated the novel theory of passive motion from the start, instead of the customary immobilization in cases of diseases of the joints. Another surgeon presented a series of beautiful Roentgen-ray pictures of bone tumors. Doyen—a blond-bearded individual of fiery temperament—savagely attacked the reader and his paper. He reminded me of some of our ultra-positive surgeons at home, who have no use for anybody on this earth but themselves. I was told that he had a great many personal enemies in France, the reasons for which I could readily understand.

I also attended a meeting of the French Surgical Society, of which Pozzi is president. I shall never forget the noise and turmoil of that meeting. During the reading of a paper or its discussion, the audience was divided into talking groups. There were such a buzz and clamor that the chairman kept continually rapping his desk and jingling a little bell in his vain and hopeless efforts to preserve a little order. Ségond is made responsible for the criticism that the French Surgical Society is a "lot of crazy dogs let loose."

The Académie de Médecine on the Rue des Sts. Pères is a dilapidated old building no longer made use of by the profession, and given over to the health authorities for vaccination purposes.

The magnificent addition to the Pasteur Institute (known as the Institut Biologique) which cost the Baroness de Hirsch $400,000, is nearly completed, and faces the institute proper on the opposite side of the street.

Dupuytren's Museum is situated on the ground of the École de Médecine. It is an antiquated, crumbling structure. It contains a nice but not a very large collection of prepared pathological specimens. It is particularly rich in illustrations of bone pathology.

The museum of the Hôpital St. Louis is, however, one of the features of Paris not to be missed by the medical visitor, particularly if he is interested in skin and venereal diseases. The specimens are masterpieces in wax representing all the varieties of dermatological lesions and tumors. These are reproduced with such extreme faithfulness that a feeling of nausea overcomes the visitor when looking at the specimens representing ulcers and the various lesions of syphilis. The coloring is truthfully natural, and the artist has not even failed to imitate the glossy conditions dependent on sebaceous secretions. This museum is in a building by itself. The walls of the main floor and gallery are lined with shelved closets containing several thousand of these wax models, which have been prepared after original lesions presenting at the clinics chiefly of Fournier and Péan. Each specimen is described on the label—sometimes with explanatory remarks. In an outside room a library, rich in literature referring to this special branch of medicine, can be consulted by the visitor. I could easily devote much more than the space of this paper allows in enumerating the specimens to be seen and studied in this wonderful museum. The visitor with plenty of time can profitably spend several weeks in this one building, and would probably emerge a fairly full-fledged dermatologist.

I shall not have much to say about London, where I spent nine days. Most of the surgeons begin work in the afternoon, about two o'clock. A great deal of general surgery can be seen. At St. Thomas' Hospital (facing the houses of Parliament on the opposite shore of the Thames), operators are usually at work in two operating-rooms separated by a wooden partition; so that one needs only to look to either side of this partition in order to see two simultaneous operations. I did not, however, see very much gynæcological surgery, for some of the operators, like Herman, do not post their operations. As a rule it is only necessary to spend the mornings visiting the various hospitals and consulting the bulletin boards, in order to select the operations one cares to witness during the afternoon. The medical journals (*Lancet* and *British Medical Journal*) devote a page to the operative work for the ensuing week at the hospitals, a decided advantage for the stranger.

I had the pleasure of meeting Cullingworth, one of London's prominent gynæcologists, at the St. Thomas' Hospital. He operates Thursdays in a small room at the back of the Adelaide ward. He looks like a man of fifty, has thin hair, large nose, grayish mustache, and wears glasses. He operates with a very few instruments. He opened the abdomen in one case of fibroid uterus, and, after accidentally injuring the bladder wall, decided the case to be inoperable, and closed up the wound. In a second case he succeeded in doing a supra-vaginal hysterectomy after a very slow and tedious operation. When I suggested the Trendelenburg position he said he had tried it once, but had got no benefit from it; and besides he had become accustomed to the old method. I noticed that he left a large portion of the uterus in the stump. Although very slow and tedious in his work, I was told that his results are excellent.

I was surprised to find a very young man of thirty-five in Bland Sutton, who works at the Chelsea Hospital for Women. He has a thin black mustache, a boyish face, and thick black hair carefully parted and brushed. For an English hospital, the Chelsea Hospital for Women is rather small. It is a newly built modern hospital of ideal construction. Before entering the operating-room the visitor is required to sign his name and address in a register, in which he reads the printed notice that he is expected during the preceding forty-eight hours not to have visited the dissecting or autopsy rooms, or to have attended a septic case. He then may enter the operating-room, where he stands at a distance from the operating-table on a graded platform guarded by railings.

During my hour-and-a-half stay I saw Mr. Sutton do the following operations: 1, Laparotomy for an ovarian cyst about the size of a large orange; 2, operation for umbilical hernia in which the whole umbilicus was exsected, and the extensive abdominal wound closed up with a buried layer of wormgut and a superficial layer of catgut; 3, removal of a small mammary cysto-fibroma; 4, flap operation for extensive perineal laceration, during which the operator unintentionally buttonholed the vaginal flap; 5, curettage and cauterization with pure zinc chloride of suppurating inguinal glands. To four patients ether was administered by means of the Clover apparatus by a woman anæsthetist. I noticed that ether is pushing its way rapidly in the operating-rooms of Germany, France, and England. Cullingworth employs ether and oxygen after the method of C. S. Cole, of New York. I noticed the free employment of nitrous oxide to start anæsthesia in some of the English hospitals.

Without entering into possibly wearisome details, I will say that I have seen the following eminent English surgeons at work: Cullingworth, Sutton, Pitts, Clutton, Butlin, Battle, and Hurry Fenwick. I shall simply allude, in passing, to an interesting gastro-enterostomy done by Battle, and to two kidney explorations done by Hurry Fenwick. In these kidney operations the operator separated the kidney from its fat capsule, and brought it clear out of the lumbar incision. After exploring the region of the pelvis—in one case actually opening and probing it, the kidney was dropped back, and the wound closed and drained. In neither case was anything found, although a stone was suspected in each. But Mr. Fenwick assured me that he had done forty or fifty operations of this kind, and had never seen any ill results.

Of course in the short space of nine days one can hardly begin to form a fair conception of the amount and quality of work done in a large city like London. But of one thing I am certain, and that is that there is less purely aseptic surgery done in London than in Berlin, Paris, or New York. This is rather a serious accusation to make against the birthplace of Listerism, but I think a few examples, which I witnessed in the largest hospitals in London, will bear me out. Thus I have seen the nurse in charge of sponges during an abdominal hysterectomy push tables, hand over basins, and otherwise subject herself to infection without washing her hands a single time. I have seen operators of surpassing skill wipe the nose, scratch the forehead, twirl the mustache, or adjust eye-glasses, and proceed with the same hand in their work (sometimes in the abdominal cavity), without dipping it even in water.

I spent a number of mornings pleasantly in taking notes and making sketches of pathological specimens in the museum of St. Thomas' Hospital. It is in a new building, and consists of a main floor and two galleries, the walls of which are shelved and piled with hundreds of jars containing pathological specimens. There are four descriptive catalogues giving very interesting details regarding each specimen. In the reading-room of the hospital I noticed only one American journal—the MEDICAL RECORD.

At 20 Hanover Square, a very fashionable neighborhood, I attended a meeting of the British Gynæcological Society. Several dozen members were present, mostly in evening dress. Contrary to the atmosphere of the French Surgical Society (and some of our American societies, I am sorry to add), everything presented an air of order and quiet refinement. McNaughton Jones presided. He has come over from Dublin (I was told by a member), and has immediately taken rank among the foremost of London's fashionable consultants. He looks about sixty, and has magnificent thick steel white hair and beard. His bearing is very distinguished, and his discussions were exceedingly logical and convincing. I was particularly gratified to hear in the course of the evening continuous allusions to the work of American gynæcologists.

I cannot close these brief extracts of my experience with the profession abroad, without alluding to the fact that the American surgeon—particularly the gynæcologist and abdominal surgeon—is positively forcing himself in a very emphatic manner upon the notice of our colleagues across the ocean. The time has already arrived when the names of Thomas, Emmet, Murphy, Senn, Frank, Kelly, Noble, Polk, Wylie, Mundé, Boldt, and others are perfectly familiar to the workers in surgery and gynæcology on the other side; and it was a great pleasure to me to note that, in England and France particularly, the stars in our firmament were alluded to with the same feelings of reverence and respect as at home.

112 EAST SIXTY-FIRST STREET.

On the Free Use of Drinking-Water in Acute Hemorrhage.—Louis Kolipinski says that the prime indication in the treatment of acute hemorrhage, after the temporary or permanent closure of the bleeding vessels, is to refill the vascular septum with its normal fluid without delay. A plan which yields brilliant results is the very liberal exhibition of drinking-water. He cites the case of a girl, aged eighteen years, suffering from typhoid hemorrhage, who drank twenty-four tumblers of water in one night. The next morning the patient had revived completely and her radial pulse was strong at 108 beats per minute. Cold-poultice treatment was also used.—*Maryland Medical Journal*, December 30, 1899.

Deformity following Excision of the Knee.—Henry Ling Taylor says the knee of a child should practically never be excised for ostitis. Excessive shortening often follows from destruction of the epiphyseal junction, and there is often recurrence of deformity from failure to get bony union. Opening and washing out, with erasion when necessary, will preserve the epiphyseal line.—*Pediatrics*, December 15, 1899.

Incipient Insanity.—J. Outterson Wood says that some of the most distressing cases of uncertifiable mental disorder are those in which the patient, although otherwise sane, is tormented by "horrid thoughts." There is danger of a breakdown of mental control and the development of an impulse which may end in disaster. The general health should be improved, insomnia overcome by twenty grains of sulphonal on alternate nights, indigestion carefully treated, and cheerful surroundings provided for the patient, or some new and healthful outside elements introduced into the family. A nervine tonic may be given, and hypnotic treatment is sometimes of value.—*Treatment*, December 14, 1899.

Cases of Bullous Eruption of Undetermined Nature.—T. Colcott Fox relates an unusual instance of bullous eruption affecting the entire body in a woman aged thirty-six years, which differed from pemphigus in commencing as inflammatory nodules of considerable size, which rapidly became vesicular and the contents blood-stained. The patient steadily lost ground and died. The total duration of the eruption was nine weeks. After rupture of the bullæ there were ulcerations which spread as in phagedæna. The first suspicion was that the affection was due to iodide of potassium, but no history could be obtained that this drug had been taken. Another theory was based upon the possibility of glanders infection.—*British Journal of Dermatology*, December, 1899.

The Offspring of Congenital Syphilitics.—George Pernit relates the history of a congenitally syphilitic mother who, out of seven pregnancies, gave birth to only one living child at full term. This boy was a weakling who showed no actual signs of syphilis. The father, although blind, could not be made out to be syphilitic. The mother showed unmistakable signs of congenital syphilis.—*British Journal of Dermatology*, December, 1899.

Extra-Genital Chancre.—W. T. Freeman records an instance of chancre upon the outer side of the right gum in a girl, aged sixteen years. It was not known how long the ulcer had existed. There was some swelling of the submaxillary gland, but it was not noticeably hard. A consultation on admission to the hospital confirmed the diagnosis. The ulcer steadily healed under mercurial treatment. An erythematous rash subsequently developed.—*British Journal of Dermatology*, December, 1899.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO. 51 Fifth Avenue

New York, January 20, 1900.

A SET-BACK FOR OSTEOPATHY IN KENTUCKY.

KENTUCKY, in striking contrast to some of the other States, has ever studied the best interests of the community at large, and of the medical profession in particular, in stoutly and persistently discountenancing the practice of osteopathy within its borders. Quite recently a decision has been rendered in the Jefferson circuit court of Kentucky which is probably the most discriminating and apposite of any that have yet been delivered in regard to osteopathy.

The judgment referred to was the result of a suit brought by a professor of osteopathy against the State board of health of Kentucky, to enjoin it from prosecuting him for practising osteopathy in the State. By the statutes of Kentucky the following regulations must be complied with in order to practise medicine:

"1. A diploma from a reputable medical college legally chartered under the laws of this State. 2. A diploma from a reputable and legally chartered medical college of some other State or country, indorsed as such by the State board of health. 3. Satisfactory evidence from the person claiming the same that such person was reputably and honorably engaged in the practice of medicine in this State prior to February 23, 1884. 4. Satisfactory evidence from any person who was reputably and honorably engaged in the practice of medicine in this State prior to February 23, 1884, who has passed a satisfactory practical examination before the said board."

The plaintiff in the case against the Kentucky State board of health did not possess the first, third, or fourth qualification named in the above-quoted regulations, but had received a diploma from the American School of Osteopathy at Kirksville, Mo., a legally chartered school under the laws of that State. Therefore, as by another section of the Kentucky statutes it has been enacted that there should be no discrimination against any institution, school, or system of medicine, the question to be decided was whether the American School of Osteopathy at Kirksville, Mo., was a reputable medical college. The State board of health fully investigated the said school. It sent a committee of three of its most prominent physicians to that institution, who after an exhaustive examination of its equipment and facilities for teaching, and after satisfying themselves as to whether its professors were competent or incompetent educators, came to the conclusion that the American School of Osteopathy at Kirksville was not a reputable medical college, and that consequently the diploma from it held by the plaintiff was entitled to no respect. That this decision was justified by the facts of the case was undoubtedly proved absolutely. Of the fifteen professors of the faculty only three were possessed of a degree in medicine, while the explanation of osteopathy given in the catalogue of the institution is a farrago of the greatest conceivable nonsense. The plaintiff had the unblushing assurance to testify that osteopathy cures all diseases except cancer, syphilis, and consumption; that he treats Bright's disease by manipulation, and diabetes by manipulation stimulating the renic splanchnic; that he treats diphtheria by manipulation, stimulating the vasomotor centre in the back of the neck, and by putting the finger down the throat of the patient, and manipulating the soft palate or fauces; that he treats scarlet fever, lock-jaw, milk leg, varicose veins, dropsy, retention of urine, fistula in ano, anal fissure, acute rheumatism, hip-joint disease, simple, benignant and malignant tumors, chronic syphilis, eczema, shingles, carbuncles, bone felons, bruises, puerperal convulsions, flooding after child-birth, laceration of the cornea of the eye, all by manipulation; but he refused to state how or in what manner this manipulation is applied. Many of the foremost physicians of Kentucky gave evidence for the defence, among whom was Dr. J. M. Matthews, the president of the American Medical Association, who testified that he understood the theory and practice of osteopathy, and that osteopathy is not a system for curing diseases, and is to be feared for dangerous results which would naturally be caused thereby. He furthermore stated that manipulation of the body, instead of being a cure for Bright's disease and diabetes, and for scarlet fever, appendicitis, retention of urine, and other diseases which osteopaths aver could be cured by manipulation, would do the patient no good, but on the contrary positive harm. Dr. Matthews even went so far as to assert that osteopathy, upon the lines of the treatment laid down by the plaintiff, was as a system very foolish and would be more likely to kill patients receiving it than benefit them. According to the testimony proffered in the foregoing trial, massage is the magical means by which osteopaths perform their vaunted cures. The fact that massage exerts a beneficial effect upon a certain class of maladies will be denied by no physician. But when its exponents claim that it will relieve and cure organic disease, it is time indeed that the gullible public should be defended against itself.

Perhaps even in the middle ages, before medicine was a science and quackery of every description was rampant, there has never been a time when charlatans abounded and flourished as they flourish in this country now. Four or five States—in this enlightened age and in a land which proudly lays claim to possessing among its inhabitants the most acute brains to be found in the world—actually legalize osteopathy, while faith healers, Christian scientists, hypnotists, and many others of the irregular fraternity swarm at every corner. The action of Kentucky, in excluding from the practice of medicine all those who have not gained by a course of study and by practical experience the knowledge of how to treat the ills of their fellow-men, is just both to the general public and to the qualified medical practitioner, and it is a matter for deep regret that all the States of the Union do not follow its good example.

TYPHOID FEVER IN SOUTH AFRICA.

The prediction was made, some considerable time ago, by those familiar with South Africa and with the diseases incidental to the country, that the evil most to be dreaded by the British soldiers campaigning there, and especially by those besieged in the towns, was enteric fever. In every war yet undertaken typhoid fever has probably claimed a larger share of victims than has any other disease. The explanation of this is comparatively easy. Soldiers in camp do not live under healthy hygienic conditions; their drinking-water supply is often impure, and their food and cooking, despite the utmost care that may be taken in these respects, are frequently bad. The season has now arrived when typhoid fever, the most prevalent and deadly disease of South Africa, rages most virulently.

In the Galeaka-Gaika campaign of 1877–78, and in the Zulu war of 1879, the British troops suffered so severely from its inroads that Helpmakaar had to be evacuated. Professor Sambon, writing in the *Journal of Tropical Medicine* of December 15th, says that in these two wars the British appeared to have suffered principally from a mixed infection of enteric and intermittent fevers, and refers to the fact that the term "typho-malarial" was applied by Dr. Woodward to the mixed infection while serving in the federal army of the Potomac in 1861. Dr. Sambon, however, does not think that this condition is of frequent occurrence, but is rather inclined to hold the opinion that although in a malarious region intermittent fever may develop in a patient suffering from typhoid, it happens far more often that the typhoid fever attacks a man actually suffering from malarial paroxysms, or it evokes into activity a latent malarial infection.

The origin of typhoid fever in South Africa will be doubtless thought by the majority of medical men to be the same causes which are usually considered to occasion its outbreak in other countries. On this point Dr. Sambon is not altogether in agreement with the majority, for while allowing with a certain degree of reservation that the most common cause of typhoid epidemics in South Africa is a polluted water supply, he points out that many medical practitioners in South Africa assert that the origin and dissemination of the malady depend chiefly on infected cattle. A much more potent vehicle of infection than diseased cattle is probably flies. A bright light was cast upon the harm wrought by these insects as carriers of disease by the finding of the United States commission appointed to inquire into the cause of camp epidemics of typhoid fever in this country during the war. The commission inspected the camps at Chickamauga, Huntsville, Fernandina, and Jacksonville, and found that the typhoid fever in each instance was brought by the volunteers from their State camps. The water supply was in most places good, and was not responsible for the spread of the fever. This was effected, in the opinion of the members of the commission, by the flies which swarmed in all the camps, and devoted their attentions impartially and alternately to the fecal matters in the open and not disinfected sinks and to the food of the troops. The great prevalence of enteric fever in South Africa during the hot season would appear to add further confirmation to this theory, as the statement may be made without fear of contradiction that in no other portion of the world do flies abound in such numbers.

Whatever may be the predominating cause of the origin and spread of typhoid fever, the fact remains that the disease has broken out among the British troops at the front, and especially in two of the towns encompassed by the Boers. Of the three besieged towns, Kimberly is in every respect the most healthy; its situation is good, its water supply is pure and sufficient, and its sanitary arrangements are conducted on approved modern principles. Mafeking, which is but a small place, is constructed and its sanitation managed on much more primitive lines. In addition its water supply is inadequate and impure; consequently much sickness is there present. But it is when we come to Ladysmith that we find by far the most serious condition of affairs, both on account of its natural insalubrity and owing to the large number of soldiers who have been cooped up within its boundaries for the past two months. This town even in times of peace is by no means healthy. It lies low and amidst swampy surroundings; its sanitation is defective, while its water supply is lacking in quality and quantity. It has been a military station since May, 1897, and has always suffered from a prevalence of enteric fever, dysentery, and ague. The news then that enteric fever and dysentery have broken out on a large scale in Ladysmith can be matter for no surprise, and must add greatly to the difficulty besetting the beleaguered garrison on every side.

With regard to the question of immunity to typhoid fever, or rather of comparative immunity of the British troops in South Africa, past experience teaches us that those from India and those who had been previously stationed in the country are not likely to suffer so much from the disease as are the young soldiers who have come direct from England. When typhoid fever gains a foothold among bodies of men living under the conditions in which the British troops in South Africa are compelled to live, the likelihood is that the disease will continue to spread, and that it will be very difficult to put into force measures for its successful suppression. Doubtless the medical and sanitary officers of the British army will exercise a strict supervision over the sanitary arrangements of the camps and towns, but the fact is evident that their skill and energy will be taxed to the utmost.

THE STREET AMBULANCE SERVICE IN GREAT BRITAIN.

THE London *Lancet*, in an editorial in its issue of December 9th, severely criticises the defective arrangements for removing to hospitals those individuals who may be injured or attacked by illness in the streets of British cities, and at the same time pays a well-merited and graceful tribute to the excellence of the ambulance service in American cities. Comparison in this respect between London and New York is certainly startling, and does not augur well for the intelligence and enterprise of the inhabitants of the largest and richest city in the world. The facilities provided for conveying to a hospital those in need of prompt surgical or medical care appear in London to be primitive to a degree.

The Lancet comments on the matter thus: "Considering the wealth of London, its position as a centre of civilization, and the enormous number of its street accidents, there is probably no city in the world where such inadequate provision is made for dealing with these misfortunes. The unhappy victim of accident or sudden illness in our streets depends for his safety on the intelligence of the chance passer-by and the nearest policeman. . . . A little crowd of well-meaning but ignorant and therefore dangerous persons surrounds the patients, limiting the supply of fresh air and precluding any medical man, if he happens to be near, from even seeing that there is a case in which his presence might be of immediate service. By this time a policeman has arrived, and with the help of one of the original witnesses of the accident the victim is helped into a cab, and probably arrives at a hospital with a compound instead of what was at first a simple fracture, or with an extensive cerebral hemorrhage where there might have been only a limited one had he been in medical hands before removal from the street. Obviously the sooner that medical aid can reach the victims of illness or street accident the better. Yet there is absolutely no method for quickly bringing such aid to the injured, and as a community we rely simply on the dangerous alternative of getting the injured by the best means that chance to be available to the nearest place where we may expect to find medical aid."

The foregoing strictures are decidedly pungent, but to the person who is acquainted with London they will appear to be fully justified by the facts of the case. Horse ambulances and ambulance calls are unknown in Great Britain, and the sick or injured person in the street is either hustled into a cab or borne by policemen on a hand-stretcher, and, as *The Lancet* puts it, horse ambulances are a dream of the future for the injured Londoner. Americans are ofttimes accused by Britishers of unduly extolling the methods and conveniences of their own country. It is therefore grateful and refreshing when a journal of *The Lancet's* repute freely acknowledges the superiority of our system of dealing with the sick and injured in the streets, and furthermore advises the towns of its own land to go and do likewise. The article in *The Lancet* will doubtless tend to arouse the sense of the usually somewhat phlegmatic British public to the necessity for reforms in this line.

THE WAR IN SOUTH AFRICA: ITS MEDICAL ASPECTS.

THE war in South Africa between the British and the two Boer republics is going to be a protracted affair, and the lessons to be learned from it by other nations will certainly be of the first importance. In military circles the operations are being watched with intense interest, for since hostilities broke out questions have been started relating to the management of artillery, to the value of rough-riding cavalry, to the difficulty of sea transport, and to the methods of maintaining long lines of communication—we mention only the points which occur immediately to our mind—whose answers are of the greatest importance to all military powers. The medical arrangements of this campaign will similarly form an object-lesson for all medical men, as well as for those who in a business or humanitarian capacity have to take into consideration the way in which the modern soldier is cared for during war.

We have therefore decided to give our readers week by week a *résumé* of medical events as they occur in South Africa, prepared for us by a special correspondent who is in an exceptional position for hearing all that is to be heard from official or private sources. Our readers may rely upon his facts.

(From our Special Correspondent.)

A Summary of Past Events: Sir George White's Force.—It will be convenient to summarize as briefly as possible the medical events of the war up to the end of 1899, so that the whole story may be consistently told from beginning to end.

In October, when war broke out, the British War Office sent out the Natal field force under Sir George White, who took with him Lieutenant-Colonel R. Exham, R.A.M.C., as principal medical officer. Sir George White's business was to arrest the rush of the Boers down to Natal to the coast, and with some losses and much hardship he succeeded. But although he saved Pietermaritzburg and Durban by hard fighting, he was hemmed in at Ladysmith, where he and his medical officers at present are. The medical experiences of this force have yet to be given to the world, and the beleaguered garrison will be fortunate if there is not a dismal tale of typhoid fever to tell. At the battles of Glencoe and Elandslaagte, as well as during the retreat from Dundee to Ladysmith, the members of the Royal Army Medical Corps behaved with great bravery, and all the arrangements for the care and transport of the sick worked satisfactorily. Surgeon-Captain Buntine, an Australian medical volunteer, was mentioned in the dispatches for conspicuous gallantry. At Dundee the British wounded, among whom was General Symons, the British officer in command, were left in the hospital, for undoubtedly the retreat was a hasty one. The Boers took possession of the hospital and looked after the wounded with every consideration, availing themselves also of the services of the British surgeons for the Boer wounded. These circumstances make all the stories of the persistence with which the Boers fire upon ambulances and hospitals rather doubtful. The Boers were found to have but rough-and-ready arrangements for dealing with their wounded.

The South African Field Force.—Hard upon the heels of Sir George White the army corps followed under Sir Redvers Buller. This consisted of the commander-in-chief's staff, two brigades of cavalry, three divisions of infantry, three brigades of artillery, certain companies of engineers, and certain regiments to maintain lines of communication. Surgeon-General W. D. Wilson, who had great Indian experience, went out on the staff as principal medical officer of the force; and the other principal medical officers were: Colonel Townshend, R.A.M.C., with the first division under Lord Methuen; Colonel Gallwey, R.A.M.C., with the second division under Sir Cornelius Clery; Lieutenant-Colonel Edge, R.A.M.C., with the third division under General Gatacre; Colonel Donovan, R.A.M.C., with the cavalry under Lieutenant-General French; and Colonel Stevenson, R.A.M.C., with the lines of communication. The army corps consisted of 52,000 officers and men with 114 guns, making with Sir George White's troops, Indian and colonial troops, and local garrisons some 70,000 men. The medical equipment for the corps consisted of 155 officers in addition to those already mentioned. Of these, 53 were detailed to the different regiments by battalions; 24 were in charge of eight bearer companies, whose duty takes them to the fighting line to bring in the wounded to the field hospitals; 64 were in charge of twelve field hospitals; 4 were in charge of stationary hospitals, 8 were in charge of general hospitals, and 2 were in charge of medical stores at the base.

Hospital Ships.—Two hospital ships were sent to South Africa by the War Office, and two were afterward dispatched at the expense of private donors, viz., the *Princess of Wales* and the *Maine*, whose outfit was defrayed by the American women of London. All the hospital ships were transformed passenger ships, but the transformation was very complete, for in each case the insides were ripped out, the familiar furniture abolished, the woodwork painted, and the saloons transformed into airy wards containing swinging cots.

Lay Assistance.—Hardly had the war commenced when Sir George White met with a serious reverse, losing two infantry battalions, and a battery of mountain infantry amounting to a force of thirteen hundred men. To lose the men was bad, but the loss of more prestige was worse for the British. It must be remembered that the seat of war, especially in northern Cape Town, was occupied by British subjects allied by blood to the Boers. These men were sitting on a fence until this event decided many of them to throw in their lot with the temporary victors. Thus the British forces were decreased as the Boer forces were increased, and the British government at once decided to send out more troops. The Royal Army Medical Corps was by this time becoming depleted, and lay assistance was required to carry on the work left behind them by those who had gone to South Africa, when it occurred to the director-general that as he must fall back upon laymen he might as well have the advice of great civil surgeons. Accordingly Sir William MacCormac, the president of the Royal College of Surgeons of England, Mr. Frederick Treves, and Mr. G. H. Makins were appointed civil surgeons to the forces; and later Mr. Watson Cheyne, Mr. Cheatle, Sir William Stokes, and Mr. Kendal Franks were similarly requisitioned. The Royal Army Medical Corps did not resent having the lay surgeons put over their heads in an advisory capacity, but on the contrary welcomed their assistance. This fact will have an important development in Great Britain, it is believed, for it will lead to the formation of a sort of scientific reserve to the Royal Army Medical Corps, consisting of operating surgeons whose services can be obtained by the army in times of peace. Such a system exists in Germany, and will probably be adopted in Great Britain.

The Progress of the War.—The progress of the war became most unfortunate for the British. When Sir Redvers Buller arrived at the Cape, he was compelled to abandon his plan of marching at the head of an army to the capitals of the Orange Free State and the Transvaal, as British forces surrounded at Ladysmith and Kimberley demanded immediate relief. Consequently Buller and Clery went to Natal to try to get into Ladysmith, Methuen went to try to get into Kimberley, French went to Colesberg, and Gatacre to Stormberg to check the Boers in north Cape Town, now become numerous by rebellion reinforcements. The army corps thus split up met with reverses in every direction, and reinforcements were ordered out under Lord Roberts.

This brief summary of previous events may be known to most readers, but it seemed to me to be necessary, if the information to follow about the medical events with the various columns is to be quite comprehensible. I shall in my next article describe in detail the equipment of the Royal Army Medical Corps, and give an account of the way in which the wounded have fared in the engagements which have now taken place all over the field of war.

News of the Week.

The Genito-Urinary Section of the Academy of Medicine.—At a recent meeting of the Genito-Urinary Section of the New York Academy of Medicine, Dr. W. K. Otis was elected chairman for the ensuing year. The date of meeting was also changed from the second Tuesday to the third Wednesday of the month.

Delaware County (Pa.) Medical Society.—At the annual meeting held at Chester on January 12th the following officers were elected for the ensuing year: *President*, Dr. McMasters, of Ridley Park; *Vice-President*, Dr. Gallagher, of Glenolden; *Secretary*, Dr. Leon F. Fussell, of Media; *Treasurer*, Dr. D. W. Jefferies, of Chester; *Librarian*, Dr. Trimble, of Lima; *Reporter*, Dr. M. A. Neufield, of Chester; *Censors*, Dr. D. W. Jefferies, of Chester, and Dr. Bartleson, of Clifton Heights.

Symptoms of Sanity in a Christian Scientist.—A woman in Boston was run over by the cars while returning from a Christian Science meeting, and her foot was crushed. She refused to go to a hospital and insisted upon being taken to a Christian Science healer. The latter, however, was strangely sane, and refused to give the woman any treatments, but advised her removal to a hospital at once. She was taken to the City Hospital and the foot was amputated. The healer said the woman had attended only one meeting, and was evidently carried away with the idea that the science of Christian healing included surgical cases, which, however, "scientists" were not prepared to treat. The healer's remarks were manifestly heretical and call for a bull of excommunication from "Mother."

English as She is Wrote in Philadelphia.—The putative editor of a medic journal some miles below New York, with that fatal fatuousness which impels men of his sort to rush in where angels fear to tread, has set himself the task of teaching others how to write. The following is a sample of how he does it. He is berating a correspondent for daring to criticise one of his myriad lapses, and says: "The word-fetich man, the sneerers at change and progress in philology, are amusing people, at least until dogmatism and silliness reach madhouse-intensities. To refract a person, or his eyes, are terms used thousands of times every day by all oculists, and aid us so much in expressing facts that if they were as illogical and absurd as the pernickety sticklers themselves, could not be killed; nor can they be kept from the written language when so habitual in colloquial use."

A Scientific Study of the Results of Hanging has been begun under the auspices of Jefferson Medical College. In the case of a murderer hanged recently in Philadelphia it was found that death had not resulted from either fracture of the vertebræ or asphyxia, but from traumatism of the structures of the neck, which were much lacerated. The crystalline lens was intact. Life persisted for eighteen minutes after the falling of the drop, although it is thought consciousness was lost at once.

The Plague.—Assistant Surgeon Havelburg of the Marine-Hospital service reports from Rio de Janeiro on January 11th that there had been one death from the plague in that city, the diagnosis having been confirmed by bacteriological examination. A Brazilian of this city, in a communication to the daily papers, denies this report, affirming that he had received a dispatch on January 12th in which Dr. Nuno Andrade, chief of the health department at Rio, is quoted as saying that no cases of the disease had yet been found there. Paraguay has declared a quarantine against all vessels which had sailed from suspected ports since the first of this month.—In Bombay the plague is reported to have reappeared, the number of deaths in the city on January 12th having been three hundred and seventy-six. The average death rate, when no epidemic prevails, is seventy-five.—In Japan the disease still exists, but the authorities have succeeded in preventing any epidemic as yet. In Kobe and Osaka, where the danger is greatest, there is an average of only about one case a day reported. The health officials in Tokio have instituted a thorough cleansing of the city, every house being visited and, if necessary, swept out and disinfected.—In Honolulu twenty-two deaths had occurred from the plague up to January 9th. Nearly every case has ended fatally. Among the deaths one was of an American woman, and this has caused alarm, as it refutes the statements made by the health authorities that the disease was confined to the natives and the Asiatics. The lifting of the quarantine on Chinatown just before Christmas is thought to have been responsible for the fresh outbreak of the disease. On December 31st it was decided to destroy all infected houses. Since then five sections of Chinatown have been destroyed. As soon as a case of sickness is found or a suspect discovered the board of health physician examines it. If found to be the plague the victim is removed to one of the two camps and the premises are burned. In this way it is hoped to stamp out the infection. In the mean time a house-to-house inspection is going on, especially in the Asiatic quarter. This inspection has revealed several cases of leprosy that had escaped the vigilance of the authorities. The port quarantine is absolute. No passengers are allowed to depart until they have spent ten days in quarantine, and in-coming steamers cannot put any passengers ashore nor can any one board them. Many tourists on the island are unable to get away. Freight is carried to the steamers in lighters, and no vessel is permitted to tie up at the wharf.—Two cases of the plague are reported from Adelaide, South Australia, one of them terminating fatally. The patient was a runaway sailor from a British bark.—The disease is apparently beginning to spread in Manila, a dispatch from there dated January 16th reporting three additional cases.—Several cases have occurred at Noumea (or Port de France) in the island of New Caledonia, lying about half-way between Australia and the Fiji Islands.

Influenza is very prevalent in England, in the provinces as well as in London, and many deaths have been caused by the disease. In Barcelona also it is said that half the residents of the town are ill, and the mortality has largely increased.

Mr. William Cadge, the well-known surgeon of Norwich, England, has been seriously ill, and a report of his death was published on December 23d. He was not dead, however, and has had the opportunity to read many kindly obituaries in both medical and lay journals.

Surgeons of the Thirteenth Regiment, N. G. S. N. Y.—Colonel Austen, of the Thirteenth Regiment in Brooklyn, has appointed Dr. James P. Warbasse assistant surgeon with the rank of captain to succeed Dr. Henry P. De Forest, who has become surgeon with the rank of Major.

Sale of Tuberculous Meat in Berlin.—The unpleasant discovery was made a few days ago in Berlin that, through the connivance of officials in the city stockyards, large quantities of condemned tuberculous beef have been smuggled through and sold to a large restaurant and to several big sausage-makers. An official investigation has been ordered.

War on the Cigarette.—A bill has been introduced into the New York legislature to regulate the sale of cigarettes. Dealers must obtain a tax certificate and must make oath that the cigarettes to be sold contain no injurious drugs or narcotics. The application for a certificate must be signed by five reputable citizens of the place where the applicant resides, and no cigarettes can be sold to persons under eighteen years of age.

Yellow Fever in Mexico.—It was officially declared some time ago that Vera Cruz was free from yellow fever, but a number of new cases have broken out recently, and several deaths have occurred in the military and civilian hospitals. The sanitary agent stationed in Orizaba reports that the yellow fever has also reappeared in that city. One case was noted in Tehuantepec on January 2d, but since that date no cases have been reported there.

A Physician to be Court-Martialled.—It is reported from Cape Town that Mr. Hoffman, a member of the Cape Assembly, who joined the Boers as a surgeon, is a prisoner at De Aar, and in all probability will be court-martialled.

The Berks County (Pa.) Medical Society, at its annual meeting held at Reading on January 9th, elected the following officers for the ensuing year: *President*, Dr. F. W. Frankhauser; *Secretary*, Dr. James W. Keiser; *Treasurer*, Dr. A. S. Raudenbush.

Consulting Physicians for the State Hospitals.—A bill has been introduced into the New York legislature by Senator Ambler, amending the insanity law, so as to provide for the appointment of a staff of consulting physicians for hospitals for the insane, whose duties shall be similar to those of a staff of consulting physicians to a general hospital.

Dismissal of Hospital Internes.—The internes of the Metropolitan Hospital (the Homœopathic City Hospital on Blackwell's Island), in order to express their dislike for the superintendent, hung the latter in effigy one night and then danced around the dummy. Their prank was discovered and reported to the commissioner of charities, who at once, without a hearing, expelled the entire house staff, consisting of twelve young graduates.

The Cumberland County (Pa.) Medical Association, at its annual meeting held at Carlisle on January 9th, elected the following officers for the ensuing year: *President*, Dr. J. C. Davis, of Carlisle; *Vice-Presidents*, Dr. M. M. Daugherty, of Mechanicsburg, and Dr. George W. Borst, of Newville; *Secretary*, Dr. Hildegard Lonsdorff, of Carlisle; *Assistant Secretary*, Dr. J. A. Lefever, of Boiling Springs; *Treasurer*, Dr. J. H. Bowman, of Riverton.

A Mineral Diet.—A dime-museum performer, who was called "the man with ostrich stomach," has been earning an honest living for a year or so by swallowing pins, nails, coins, watch chains, and other dainties. He got along fairly well until he began to gorge himself with pins, when his stomach rebelled, and he was forced to go to a hospital in Brooklyn. There he was operated upon, and two nickel watch chains, one brass chain, two latch keys, six hairpins, one hundred and twenty-eight common pins, ten two and one-half inch iron nails, two horseshoe nails, one finger ring set with a stone, and several other equally digestible articles were removed.

An Epidemic of Typhoid Fever due to Drinking-Water.—A small epidemic of typhoid fever has occurred in a section of Wayne, a suburban town near Philadelphia, in which investigation disclosed that in all of the houses in which cases occurred the water supply was derived from a spring and two dug wells. On chemical analysis of the water the presence of a large percentage of chlorine was found, indicative of sewage contamination. The surface of the ground in the neighborhood of the wells was covered with stable manure. The first of the cases occurred in a man who returned from Europe with the disease, and was treated at a house the drainage pipe of which runs within forty feet of the spring and one of the wells from which the water supply was obtained. The disease developed shortly afterward in the neighborhood supplied with water from this source. No cases occurred in the districts supplied with water from the two other sources.

A Female Hygienic Exposition will be opened in St. Petersburg the latter part of January. The object of the exposition is to bring before the public all that has been done by women to make hygienic living more attainable.

The Brooklyn Society of Neurology.—At the annual meeting of this society, recently held, Dr. William Browning was elected president; Dr. R. C. F. Coombes, vice-president; and Dr. W. H. Haynes, secretary.

Dr. Victor C. Vaughan, professor of hygiene and of physiological chemistry in the University of Michigan, and late lieutenant-colonel Thirty-third Michigan volunteers, U.S.A., has been elected surgeon-general of the Spanish-American War Veterans.

Philadelphia Medical Club.—At the annual meeting held January 5th, the following officers were elected for the ensuing year: *President*, Dr. J M. Anders; *First Vice-President*, Dr. H. A. Wilson; *Second Vice-President*, Dr. W. L. Rodman; *Secretary*, Dr. Guy Hinsdale; *Treasurer*, Dr. F. Savary Pearce.

Malaria in Central Asia.—According to the *Turkestan Messenger*, five hundred and ninety-five persons died from malaria in the latter half of September in Tashkend. The number of persons severely ill with the disease during that time was one thousand seven hundred and eighteen.

Marine Hospital for Honolulu.—The President has issued an order setting apart seven acres, more or less, out of the government reservation east of the "Punch Bowl," in the island of Oahu, Hawaii, as a site for a United States marine hospital for the port of Honolulu.

An Unusual Breach-of-Trust Case.—A claim of $5,000 has recently been brought against a Hartford, Conn., physician on the following somewhat extraordinary grounds: The doctor had agreed to take charge of a maternity case, but was not present when the child was born; a few days later the child died. The physician was then sued for breach of trust in the case and as being responsible for the death of the child. The defence demurred to the complaint, stating that the father could not have acted as the agent for the child, and that the doctor did not contract with the unborn child for its delivery. As the case was brought because of the death of the child, the defence claimed that it should be quashed. The judge ruled that suit may be brought in behalf of a child unborn when its parents had made a contract to deliver and care for it after its birth, and found true cause for action on the part of the parents. The case has caused considerable interest throughout the State, and is the first of the kind brought under Connecticut statutes.—*Boston Medical and Surgical Journal.*

Drs. James A. Roache and James P. Glynn, of Brooklyn, have been appointed physicians in the department of charities in that borough.

Dr. Sidney L. Laselle, of Orange, N. J., has started for Hainan, China, where he will serve as a medical missionary. He has gone out under the auspices of the Presbyterian Board of Foreign Missions.

A Breisky Memorial.—On December 14th, in the obstetrical clinic of the German University of Prague, a memorial to Professor Breisky was unveiled in the presence of a large assembly.

Insanity in the Army.—Fourteen soldiers, declared to be insane, have been sent to Washington from the Presidio military reservation in California. Nearly all of them became insane while on duty in the Philippines.

Medical Practice in Brazil.—According to a recent decree the holder of a medical diploma from a foreign university of recognized standing is now allowed to practise in Brazil. Formerly foreign physicians desiring to practise in that country were obliged to pass an examination in the Portuguese language.

The German Balneological Congress will be held in Frankfort-on-Main on March 8–13, 1900. The sessions will be held in the forenoon of each day, three of the afternoons being devoted to excursions to Soden, Nauheim, and Homburg. Information regarding the congress may be obtained from Dr. Brock, 18 Melchiorstrasse, S. O., Berlin.

The Second Cuban Medical Congress.—The following is the constitution of the executive committee of the proposed congress of Cuban physicians: *President*, Dr. Vicente B. Valdés; *First Vice-President*, Dr. Diego Tamayo; *Second Vice-President*, Dr. Rudesindo García Hijo; *Treasurer*, Dr. Antonio González Curquejo; *Secretaries*, Drs. Enrique Núñez, José A. Presno, and Jorge Le Roy.

Quack Medicines in Vienna.—The Austrian government has forbidden the sale in Vienna of "pink pills," a quack remedy made in Paris. Physicians are forbidden to prescribe them, druggists and others are forbidden to sell them, newspapers are forbidden to advertise them, and the distribution of circulars, through the mail or otherwise, setting forth their alleged virtues is also forbidden. The reason given for this action is that the composition of the pills is kept secret, and further that the remedy is put forth as a cure-all.

The Montefiore Home.—We learn from the fifteenth annual report, just issued, that six hundred and nine patients were treated during the year at the Montefiore Home for Chronic Invalids, with a death rate of 16.91 per cent. One hundred and ninety-four were discharged, of whom thirty-six were cured, and one hundred and fourteen improved. Only about a third of the applicants for admission during the year could be received, owing to the lack of sufficient accommodations. The directors of the home are building a sanatorium at Bedford Station, Westchester County, to which it is purposed to remove all of the patients suffering from pulmonary tuberculosis.

A Foreign Body Removed from a Bronchus.—Professor Schraetter, of Vienna, recently removed a piece of lead from the lung without a cutting operation. The foreign body, which had entered a bronchus, was located by means of the *x*-rays at the level of the fourth rib. By means of the bronchoscope and a specially contrived forceps the lead was extracted without the necessity of a resort to tracheotomy.

The Tri-State Medical Association of North Carolina, South Carolina, and Virginia will hold its second annual meeting at Charleston, S. C., on February 20, 1900. The meeting last year was in Charlotte, N. C. The set discussion at the coming meeting, to be opened by Dr. Paul A. Barringer, of the University of Virginia, will be on the negro, his sexual life, his character, and the influence of his past and present surroundings.

Virchow Jubilees.—A man whose life has been so full and so varied as Virchow's finds, after passing his three-score and ten, the jubilees crowding thick and fast. On November 25th the University of Würzburg celebrated the lapse of fifty years since Rudolph Virchow delivered his first lecture there. In the vestibule of the Pathological Institute was placed a bust of the great pathologist crowned with a wreath, and Prof. v. Rindfleisch delivered an oration in which he reviewed the development of the science of pathology during the half century, and dwelt upon Virchow's influence in that development.

A Duel between Hospital Internes.—Two hospital internes at Bordeaux quarrelled, and the trouble ended in a duel in which the four seconds were also internes. One of the principals was killed, and the other was tried for murder, and the four witnesses were also brought into court as accessories. Thus far the case was exceptional, for French duels as a rule are noted for their bloodlessness; but the subsequent proceedings were eminently Gallic. When arraigned in court the accused said the murder was a pure accident, for each duellist shot at the word of command without having time to take deliberate aim; therefore of course neither could have intended to kill the other, since he had not aimed at him. The survivor expressed his regret at the unfortunate occurrence, and the four witnesses, who were also on trial, assured the court that they thought he really was sorry; so the judge acquitted them all.

The Craig Colony.—The following constitute the board of consulting physicians and surgeons for this colony: *Neurologists*—M. Allen Starr, New York City; George W. Jacoby, New York City; Henry Hun, Albany; James W. Putnam, Buffalo. *Surgeons*—Charles McBurney, New York City; Roswell Park, Buffalo;

John W. Whitbeck, Rochester. *Physicians*—Charles E. Jones, Albany; Charles Cary, Buffalo; William S. Ely, Rochester. *Orthopedic Surgeons*—Henry Ling Taylor, New York City; Louis A. Weigel, Rochester. *Ophthalmologists*—Lucien Howe, Buffalo; Wheelock Rider, Rochester; George M. Gould, Westfield. *Gynæcologist*—Matthew D. Mann, Buffalo. *Pathologist*—Ira Van Gieson, New York City. *Bacteriologist*—Harlow H. Brooks, New York City. *Psychologist*—Boris Sidis, New York City. *Pathological Chemist*—Christian A. Herter, New York City. *Dentist*—Charles J. Mills, Mount Morris.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending January 13, 1900. January 5th.—Assistant Surgeon R. W. Plummer detached from the *New Orleans* and ordered to the *Petrel* and also to the Cavite naval station. Assistant Surgeon D. G. Beebe detached from the *Bennington* and ordered to the *Petrel*.

Hospital Fire in Santiago de Cuba.—The yellow-fever hospital, situated on an island across the bay from Santiago, was destroyed by fire on December 20th. The building had been used by the Spanish as a pest house before the American occupation. During the epidemic last summer many hundreds of American soldiers and civilians were treated there. The adjoining building, containing a hundred bodies of American soldiers in sealed caskets, ready to be shipped to the United States, was saved by the firemen. The fire was of incendiary origin. A new hospital will be erected immediately on the same site.

Mr. Felix Morris, a well-known actor, who died in this city on September 13th from pneumonia, was educated as a physician at Guy's Hospital, but after obtaining his qualifications abandoned medicine for the stage.

The Late Dr. Charles E. Jones.—At a meeting of the board of managers of the Craig Colony, held at Sonyea, N. Y., January 9, 1900, the following note was recorded in the minutes:

"The board of managers of the Craig Colony record with genuine sorrow the death of one of their number, Dr. Charles E. Jones, of Albany, N. Y., who died in that city December 1, 1899. He was a man who had won a high place as a skilful and faithful physician, a man of upright dealing always, and a man who was regarded with affectionate consideration by patients and friends alike. He was the late Governor Flower's family physician, and upon signing the bill creating the Craig Colony, the governor appointed Dr. Jones a member of the board of managers, which position he held from the founding of the colony to the day of his death. He took the deepest interest in this charity, and greatly aided its development by his earnest zeal and broad-minded consideration of all matters relating to it. We feel his death to be a public loss which this board especially deplores.

"Signed for the board of managers of the Craig Colony: FREDERICK PETERSON, President; H. E. BROWN, Secretary."

Obituary Notes.—DR. CHARLES A. SIEGFRIED, medical inspector United States navy, in charge of the naval hospital at Coaster's Harbor Island, died at his cottage in Newport on January 14th, of pneumonia, after an illness of only two days. He was a graduate of the Jefferson Medical College in 1872, and entered the medical corps of the navy in the same year. He had had charge of the naval training-station at Newport for several years, though during the war with Spain he was temporarily stationed at Key West. He was to have been an official delegate to the International Medical Congress at Paris in August.

DR. ERNEST SCHRODER died at his home in Brooklyn on January 12th, of apoplexy. He was born in this city in 1852, and was a graduate of the Long Island College Hospital Medical School in 1882.

DR. JOHN CLARK CLEARY died in Port Chester, N. Y., on January 14th, from typhoid fever. He was born in Clyde, N. Y., thirty-one years ago, and was graduated from the medical department of the University of Buffalo in 1898.

DR. WILLIAM H. LYONS, aged fifty-three years, died January 13th, at his residence in this city. He was born in Ireland, but his parents removed to New York when he was three years old. He was a graduate of the College of Physicians and Surgeons in the class of 1877, and had been an active practitioner in this city for twenty-five years.

DR. GUSTAVE MAHE, formerly of New York, died suddenly in Sioux City, Iowa, on January 11th. He was born in Paris, but came to this country with his parents when he was nine years old. He was a graduate of the Bellevue Hospital Medical College in 1889.

DR. J. C. MULHALL, of St. Louis, was found dead in his office on January 11th, having killed himself with a pistol. He was forty-nine years of age. He was a graduate of the St. Louis Medical College in the class of 1873, and the following year obtained the licentiate of the Royal College of Surgeons in Ireland. He was professor of diseases of the throat and chest and of climatology in the Beaumont Hospital Medical College. He was a member of the American Laryngological Association, the American Climatological Association, the American Medical Association, and the Missouri State Medical Society.

DR. WASHINGTON L. ATLEE, of Philadelphia, has died at his home of heart disease. He was born in May, 1842. At the outbreak of the Civil War he enlisted as a hospital steward, and served until the end of the war. He afterward entered the Jefferson Medical College and was graduated in medicine in 1870. He was a son of Dr. Washington L. Atlee, who performed the first ovariotomy in Philadelphia in 1849.

DR. J. ELMER COOK died at Harrisburg, Pa., on January 13th, at the age of fifty-six years. During the Civil War he was a soldier in the Union army.

DR. I. LEO MINGLE died at Reading, Pa., on January 9th, at the age of sixty-one years. He was a graduate of Jefferson Medical College.

DR. WILLIAM A. CANTRELL died at Philadelphia on January 7th, at the age of fifty-eight years. He was graduated from Jefferson Medical College in 1862, and was for a time a surgeon in the United States army.

Progress of Medical Science.

Journal of American Medical Association, Jan. 13, 1900.

Chalicocis Pulmonum, or Chronic Interstitial Pneumonia Induced by Stone Dust.—In this paper William Winthrop Betts remarks on the increased danger to human life involved in the advent of the cyanide process of milling, and then reports on his observations among the workers of such a plant. He says that every man who works in the mill for two or three weeks becomes subject to attacks of acute bronchitis, due in great measure to the irritating effects of the dust. The bronchitis is followed by soreness along the course of the trachea and bronchial tubes, with loss of weight, shortness of breath, and general malaise. Treatment is of little avail, though much can be done to prolong life by improving hygienic conditions and stimulating the general nutrition.

Contagiosa Bullosa.—John S. Windisch records under this title his observations of epidemic pemphigus during the late Spanish-American war. He says that people from northern climates are more prone to the affection than are natives, as is seen among the English who go to China and India, the English families born and bred in India being less liable to it. This was also true of the troops encamped in our Southern States during the war; few cases were found among the Southern troops, while, on the other hand, few Northern regiments escaped. Windisch thinks it can hardly be doubted that the disease is caused by some local agency, but neither the microscope nor culture tests have shown any specific organism. The treatment is chiefly local. Mercury acts like a specific, either in the form of an ointment or as a mild antiseptic wash.

Poliomyelitis Anterior Acuta Adultorum.—Herman H. Hoppe says that because of the newer views of the pathology of poliomyelitis, and especially because of the difficult differential diagnosis, he desires to place on record two cases of this rare disease which are beyond dispute. In treating of this disease in the "Twentieth Century Practice of Medicine," Drs. Bruns and Windscheid stated that poliomyelitis is almost always seen as a complication of or sequel to acute infectious disease. The author, arguing from the two cases reported, takes a radically different view, and claims that it may occur as a primary affection, at least in the adult.

Notes on Catelectrolysis (Electrolysis) in the Treatment of Skin Disease.—Frederick J. Leviseur says that the list of skin diseases in which catelectrolysis is recommended is continually increasing. The operation is indicated whenever it is important to avoid scar formation, and when strictly limited local action is desired.

Case of Spinal Anterior Subacute General Paralysis.—C. Eugene Riggs reports a case of this disease in its bearing upon the difficulties of diagnosis that may arise between poliomyelitis and polyneuritis.

Practical Use of Radiograph and Fluoroscope in Diseases of the Lungs.—By T. Mellor Tyson and William S. Newcomet. See MEDICAL RECORD, vol. lvii., p. 67.

Case History.—B. Merrill Rickets presents an illustration of supposed axillary sarcoma in which pain was checked by applications of x-rays.

Medicine and Law.—By Duncan Eve. See MEDICAL RECORD, vol. lvi., p. 565.

Formaldehyde Disinfection.—W. K. Jaques claims numerous advantages for formaldehyde over all other methods of disinfection.

Boston Medical and Surgical Journal, January 11, 1900.

A Case of Perforating Gastric Ulcer.—F. B. Lund reports a case of this nature in which operation was performed sixteen hours after perforation had occurred. The patient, a laborer, thirty years old, made an excellent recovery. The author reviews the literature of the subject and tabulates the statistics of the operation. These show forty-five per cent. of recoveries, and in cases operated upon within twelve hours seventy-nine per cent.

A Pistol Wound of the Abdomen.—C. A. Atwood reports the case of a man who died from shock following a pistol wound in the abdomen. Laparotomy was performed but the ball was not found. At the autopsy it was found in the iliacus muscle.

The Case Method of Teaching Systematic Medicine.—W. B. Cannon approves of this form of teaching, because it requires of the student accurate judgment, close reasoning, precise expression, and wise employment of knowledge.

Relapsing Fever.—George O. Ward reports and describes a sporadic case which occurred in an Armenian immigrant in New York in 1899. Cases of the disease are rare in this country.

Tabes Dorsalis.—Alfred H. Lindström obtained marked success from postural or mechanical stretching in a case of this disease. General tonic treatment assisted in the cure.

Medical News, January 13, 1900.

Experimental Tests at Vera Cruz, Mexico, of the Doty-Fitzpatrick Serum for the Prevention and Cure of Yellow Fever.—A. Matienzo concludes from numerous experiments with the Doty-Fitzpatrick serum that, (1) although both intravenous and subcutaneous injections of the serum produced a general reaction, revealed by the hyperthermia and acceleration of the pulse, (2) they neither controlled the disease nor modified in the least the appearance, development, or duration of the symptoms of yellow fever. (3) It is not possible to form conclusions regarding the value of this method on account of the small number of cases in which it was employed. (4) The reaction caused by the injections of the toxin in the convalescents of yellow fever demonstrates Sanarelli's assertion that the curative powers of the serum in animals is not due to the antitoxin substances, and confirms by its analogy to the typhoid serum the opinion, given by some bacteriologists, that the icteroides is an Eberthiform bacillus.

Report of a Case of Scorbutus in an Infant.—Walter Lester Carr reports a case of scorbutus in a female infant of twelve months, from improper food. Beef-juice, orange-juice, and a small quantity of fresh milk were ordered; also an opiate if necessary, for excessive pain and restlessness. In three days there were few signs of the scurvy. The opiate did not have to be given, and recovery was uninterrupted.

Myomectomy Per Vaginam Combined with Shortening the Round Ligaments for Retroversion, etc.—A lecture by J. Riddle Goffe.

New York Medical Journal, January 13, 1900.

The Lung Reflex.—A. Abrams has found that when an ether spray is directed over the borders of the lungs posteriorly, the borders of these organs can be made to descend (as determined by physical signs and the fluoroscope) from two to four inches; that is, an irritation of the skin will cause the lungs to dilate. Dilatation may be recognized by diminished excursion of the lung border, extension of pulmonary percussion note, and obliteration of areas of cardiac and hepatic dulness, hyper-resonance of the lungs, and obliteration of the apex beat. From these results is deduced the following procedure to determine whether an area of dulness, say in the broncho-pneumonia of children, is due to consolidation or to atelectasis: If the latter is present, vigorous irritation of the skin will cause the dulness to disappear because the irritation leads to dilatation of the lung. If the dulness is due to consolidation, irritation will have no effect upon it.

The Therapeutic Application of Carbonic Acid Gas.—A. Rose concludes an enumeration of the various diseased conditions in which carbonic acid gas has proved of service. The list includes scorbutic ulcerations, ozæna, hyperæmia of the Schneiderian membrane, cancerous ulcerations, various neuralgias, and different skin affections. Rose has used the gas with good effect in whooping-cough, dysentery, vomiting of pregnancy, sexual neurasthenia, and vaginismus. Previous practical difficulties in the use of the gas have been the necessity of cumbersome gas-holders, defective working of the same, dangers connected with pressure, etc., and, as a consequence of all, the expense of using the gas except in the case of the well-to-do. These difficulties have all been overcome by the introduction of the steel flasks or capsules, some of which are so small that they can be carried in the pocket.

The Anæsthetic Properties of Nirvanin.—C. A. Elsberg says that this new remedy has valuable anæsthetic properties when injected into the tissues according to the infiltration method; it is less poisonous than cocaine or eucaine; it has distinct antiseptic properties; and it is a stable compound.

Echinacea Angustifolia.—This is the name of a remedy highly extolled by J. C. Stinson as a powerful aphrodisiac.

Taking Cold.—By G. V. Woolen. See MEDICAL RECORD, vol. lv., p. 846.

President's Address before the Society of Alumni of Bellevue Hospital, by C. E. Quimby.

Philadelphia Medical Journal, January 13, 1900.

The Anatomical Relations in Pelvic Hæmatoma following Labor.—W. Reynolds Wilson says that hæmatomata in the labial and perineal regions are due principally to the accumulation of blood from the branches of the pudic vein. Hæmatomas are often multiple, this showing an inherent tendency to venous rupture.

Cerebral Rheumatism.—Francis P. Morgan denies that cerebral rheumatism is a sequel of hyperpyrexia. He inclines to the belief that rheumatism is a pyæmia and that the cerebral, cardiac, and other complications are simply toxic manifestations. His treatment is symptomatic.

Diplococci—A Case of Erysipelas.—G. E. Pfahler has found and isolated a diplococcus in eight cases of erysipelas, and has produced the disease in rabbits by inoculation.

Varicose Veins of the Vulva.—William Edgar Darnall pictures a case of this sort, and says that the condition usually does not seriously complicate labor.

Excretion in the Treatment of Acute Infectious Diseases.—H. A. McCallum advocates thorough purging in the early stages of typhoid fever and pneumonia.

Certain Essential Points in the Technique of Staining Nerve Cells.—By Stewart Paton.

The Lancet, January 6, 1900.

An Address on Acidity.—J. F. Goodhart believes that all the clinical forms of acidity are due simply to uric-acid excess. This acid should be regarded as an ash common to the various metabolic processes going on in the body. The causes of the condition which presents itself for treatment include visceral sluggishness from nervous exhaustion, an hereditary condition which works itself out in gouty attacks, a sudden shock, an exhausting illness, an early defect of the kidney, or a primary manifestation of advancing age. The author finds that many persons who try to remove their acid tendencies by strict adherence to a vegetable diet will find far quicker relief from a diet containing a generous allowance of beef and mutton and less vegetable matter. The article is written in an attractive vein, and is a protest against wholesale dietetic rules without reference to the problems in each individual case.

The Histology and Prevention of Blackwater Fever.—W. H. Crosse describes a case of this affection ending in death on the sixth day. The vomitus was markedly green in color, the urine was finally suppressed, and hiccough with some dyspnœa and pain in the limbs persisted to the end. A microscopical examination of the various organs showed nothing that could not be found in the tissues of a patient who had had several attacks of malaria. The author suggested that blackwater fever bears to malaria a relation similar to that borne by hyperpyrexia to rheumatic fever. As regards prevention, he believes that all the precautions useful in guarding against malaria should be taken here. These include especially the destruction of all breeding-grounds of mosquitoes.

Internal Derangements of the Knee Joint (Popularly Called "Slipped Cartilage").—Basing his paper upon an experience of three hundred cases, W. H. Bennett discusses the causes, symptoms, and treatment of the condition and utters a plea against indiscriminate operation. Even under modern antiseptic precautions the operation is attended with some risk, and should, therefore, not be undertaken lightly.

Report on "Henpuye" in the Gold Coast Colony.—A. J. Chalmers describes a peculiar disease called "henpuye," or dog-nose, which occurs in the regions named. It consists of a nasal deformity produced by the deposition of new bone under the periosteum on the external aspect of the nasal bones, the nasal process of the superior maxilla, and the body of the latter bone itself. It is more common in men than in women, and comes on during or after an attack of yaws.

Three Cases in which Movable Kidney Produced All the Symptoms of Gall Stones.—F. Treves reports three cases, all in women aged about thirty-five years, in which attacks of hepatic colic were followed by jaundice. The latter was due, he thinks, to the pressure of a movable right kidney on the bile ducts.

Hemorrhagic Ascites.—T. Fischer's patient was a woman aged thirty-eight years who suffered from chilliness, abdominal swelling, pain, occasional vomiting, and constipation. The greater part of the belly was resonant, but shifting dulness was present in the flanks. Autopsy showed the presence of twelve pints of deeply blood-stained fluid.

Bullet Wound in the Head: Removal of the Bullet from the Nose Twenty Months Afterward.—C. Woakes records a case in which the bullet entered the skull just below the left frontal eminence. The man recovered, and came under the author's observation twenty months later with a foul discharge from the left naris. Probing detected a hard substance, which was removed, and proved to be a mass of lead covered with a bit of khaki cloth.

The Differential Diagnosis of Mongolism and Cretinism in Infancy.—G. A. Sutherland gives a table of differential diagnostic signs, but says that the final test is the therapeutic one. In the cretin thyroid extract renders wonderful service, while the Mongolian infant remains unaffected. Mongolism is a form of congenital imbecility in which certain facial appearances suggest a Chinese origin, hence the name.

Multilocular Cystic Epithelial Tumor of the Jaw; Excision of Half the Lower Jaw; Recovery.—G. P. Newbolt reports the case of a woman aged sixty-six years who had complained of the growth for twenty years. The cysts were laid open and scraped, but refilled, and a radical removal was made. No history of tooth irritation as the exciting cause could be made out.

An Unusual Case of Embolism in the Fundus Oculi.—H. W. Thomson reports a case in which an embolus was arrested in the common macular or cilioretinal artery. The occlusion lasted eight days, during which time the nutrition of the part of the retina involved was maintained by the arteria centralis retinæ, through its small branches.

The So-Called Danger from the Use of Boric Acid in Preserved Foods. O. Liebreich regards the popular prejudice against this agent as used for preservative purposes as illogical and not borne out by any information at our disposal, so far at least as concerns the absorption of either borax or boric acid from the intestine.

Case of Impacted Extra-Capsular Fracture of the Neck of the Femur.—H. E. Belcher reports a case of this sort in a man, aged twenty-six years, who was thrown from a wagon. The chief signs of injury were eversion of the foot, broadened appearance of the thigh, and the helplessness of the limb.

The Orchitis of Mumps.—C. Dukes says that the orchitis of mumps is not a metastasis; that it never arises before puberty, and that it does not occur after puberty if the patient can be kept in bed over the eighth day.

A Boy's Ear Bitten Off by a Horse.—J. M. Mote reports a case of this kind in which the ear had been taken off as cleanly as if cut by a knife.

British Medical Journal, January 6, 1900.

Observations on General Metabolism and the Blood in Gout.—Chalmers Watson sums up the result of his observations as follows: (1) The alkalinity of the blood is not diminished during an attack of gout. (2) The excretion of uric acid is not diminished, but the reverse; there is, therefore, no reason for supposing that there is temporary diminution in the capacity of the kidneys to excrete uric acid. (3) The amount of uric acid in the blood is not greater during an attack than at other times. If these points are accepted we must search elsewhere for the cause of the acute paroxysm. The author adds that it would be well in this connection if less attention were paid to the excretion of uric acid alone as the all-important factor in attacks of gout.

Scarlet Fever Without Eruption.—H. Ward Irvine reports this case, in which diagnosis was finally made after microscopical examination of the urine, showing the presence of large quantities of renal and vesical epithelia, and was verified by the subsequent desquamation.

A Case of Acquired Syphilis in a Child.—C. Hamilton Whiteford reports the case of a boy aged six years who presented himself with a sore on the eyelid diagnosed as Hunterian chancre. This diagnosis was confirmed by the appearance of secondary phenomena.

The Unimportance of the Presence of a Trace of Albumin or Nucleo-Albumin in Urines of Extremely Low Specific Gravity.—F. Parkes Weber argues that "a very faint trace of albumin" in otherwise healthy urine has no diagnostic value whatever.

Injuries Produced by a Six-Pounder Hotchkiss Shell.—J. R. Dodd reports a case illustrating the terrible effects of modern shells, and points out the vast amount of work they will entail on medical officers after a serious engagement.

A Case of Sodium Salicylate Poisoning.—H. Hilton Heffernan reports this case as being worthy of interest owing to the large dose of the drug taken (130 grains), the long period of sleeplessness (nearly four days), and the absence of depression.

Treatment of Molluscum Contagiosum with Sodium Ethylate.—Thomas F. Raven reports a case of this disease in a pregnant patient. He found the treatment by sodium ethylate entirely satisfactory.

Primary Nephrectomy for Rupture of the Kidney.—William Rogers reports a primary nephrectomy for rupture of the kidney in a girl aged fifteen years. Death ensued the following day.

Salol in Smallpox.—Charles Begg urges the use of salol in smallpox on account of its power to control irritation, to take away the desire to scratch, and thus to prevent suppuration.

The Political Aspects of Current Medical Topics.—An address delivered at a meeting of the Aberdeen, Banff, and Kincardine branch of the British Medical Association, by R. Farquharson.

Dislocation of the Radio-Carpal Joint.—Guy J. Branson reports this case as being of interest on account of the rarity of the accident.

Retention of Menstrual Blood from Atresia of the Vagina.—A clinical lecture by Charles J. Cullingworth.

Minor Epilepsy.—A clinical lecture by Sir William Gowers.

Illustration of an Improved Prostatic Catheter.—By John Ward Cousins.

Medical Press and Circular, January 3, 1900.

Anuria, Transfusion of Saline Fluid, Nephrectomy, Death.—Murrell relates the case of a woman in a semi-comatose state, who had passed no urine for two days. The temperature was subnormal. A diagnosis of toxic anuria was made. A quart of saline infusion was injected into the vein of the right arm. Although the pulse improved in quality no urine was secreted. Right nephrectomy was advised with a view of relieving a possible obstruction suggested by tenderness. Upon incising the capsule there was free escape of a serous fluid mixed with venous blood. No further exploration was attempted. Death occurred six hours after the operation. The kidneys were found to be granular, each weighing three and a half ounces, and were highly congested.

Cinematograph in Teaching Surgery.—E. Doyen advocates the use of the cinematograph, having demonstrated its advantages in a number of operations. One of these advantages is, he holds, that surgeons will be able to teach the real progress made. It has enabled the writer to correct, simplify, and perfect operative technique. The most delicate manœuvres, such as suturing the pelvic peritoneum in abdominal hysterectomies, opening the dura mater in craniotomies, etc., may be followed.

Otorrhœa and its Treatment.—Paul Rauge says that when pus from otitis media is collected aseptically and examined immediately, it is, as a rule, found to contain only a single species of microbe. The moment an artificial or spontaneous opening in the membrane occurs secondary infection becomes possible. Prevention is the best treatment for otitis.

Münchener med. Wochenschrift, December 26, 1899.

Chorea and Fever.—Kurt Witthauer calls attention to the peculiar influence of fever on the whole symptom complex of chorea as noted by him in two cases recently under his care. There was no other feature of special interest in either case. The first was of hysterical chorea in a boy, aged six years, the affection first coming on suddenly after punishment at school. The second, in a girl of twelve years, was of the rheumatic form. In both cases, immediately upon the onset of fever the twitchings became diminished, and after a few days ceased.

Dermatitis Herpetiformis.—F. Köhler reports a case of this nature in a woman twenty-one years old, and gives the four cardinal symptoms which serve to separate it from similar skin affections, such as erythema multiforme, urticaria bullosa, pemphigus, etc.: (1) Tendency to polymorphous appearance; (2) cutaneous or deep-seated paræsthesia; (3) almost constant recurrence; (4) relatively good general health.

Tuberculosis of the Nasal Duct.—O. Seifert believes the three most probable channels of tuberculous infection of the nasal duct to be: (1) Extension of the infection from the bony walls of the duct; (2) extension from the nose; (3) extension from the connective tissue of the eye.

The Early Diagnosis of Carcinoma Uteri.—Adolf Gessner states his belief that scrapings from the lining of both the fundus and the cervix uteri will establish a sure diagnosis at an early period, before any other methods could be employed.

Annual Review of the Work of the Royal Gynæcological University, Polyclinic of Prof. Dr. Amann for 1898.—Carl Braun gives a brief résumé of the work of the University Polyclinic for 1898.

The Effect of Heroin on Respiration.—C. J. Santesson, judging from numerous experiments on animals, says that heroin in small doses does not appear always to deepen respiration.

Wiener klinische Wochenschrift, December 21, 1899.

Etiology of Tuberculous Pneumothorax.—Drasche gives the results of his experience with this affection in more than forty years of general hospital practice. Of 10,212 patients with pulmonary tuberculosis 6,686 were men and 3,526 were women. Of all these, 198, or 1.93 per cent., developed tuberculous pneumothorax, 2.36 per cent. being men and 1.13 per cent. women. As to age, the greatest number of patients were between twenty and thirty years. Of the 198 cases, the trouble was in 108 cases, or fifty-five per cent., on the right side, and in 90 cases, or forty-four per cent., on the left side. Three cases were bilateral. Coughing, vomiting, straining at stool, lifting heavy weights are etiological factors. As tuberculosis develops earliest and most often in the apex, so pneumothorax is found most often in the upper lobes.

History of Carcinoma of the Pancreas.—C. Hödlmoser reports a case in a man twenty-seven years of age. The points of special interest in this case were the youth of the individual, the absence of undue quantities of fat and albumin in the stools, and the absence of sugar in the urine. A tumor could be felt in the median line. The patient had suffered intense pain at first; he hardly complained at all in the last weeks. Examination of the stomach contents showed absence of hydrochloric acid and but little pepsin, on which account a diagnosis of carcinoma of the stomach was made. The true condition was discovered at autopsy.

Rupture of the Symphysis Pubis.—Rudolf Savor says that cases of rupture of the symphysis appear in the last ten years to have markedly decreased, probably because the forceps is much less frequently employed now that we are acquainted with many other methods of delivery.

Measure of Blood Pressure by Gaertner's Tonometer.—George Kapsammer describes this very simple but ingenious instrument, which was presented by its inventor July 16, 1899, to an assemblage of physicians at Vienna.

Berliner klinische Wochenschrift, December 25, 1899.

The Specific Treatment of Tuberculosis.—J. Petruschky concludes a temperate article upon the specific treatment of tuberculosis with special reference to tuberculin. He is in accord with the dictum of the recent Berlin Congress, that no true specific is as yet known to us, and calls attention to the very important fact that the cessation of reaction to large doses of tuberculin must not always be taken as evidence of the disappearance of previously existing tuberculous tissue. He traces the gradual development of Koch's theories, and also touches upon the substance prepared by Klebs, from which much was at one time hoped. To the inquiry, "Can cases be cured by tuberculin?" he gives an affirmative reply, showing a tabulated list of twenty-two cases which had been under his own care and resulted in cure by this means. He call attention to the fact that those patients who in the course of the tuberculin cure have ceased to react thereto may after three or four months again become sensitive, so to speak, to the remedy. This he regards as a favorable circumstance, for it enables us again to bring the system under the effects of the remedy. From the serums of Behring and Maragliano he expects but little. Moreover, for cases of mixed infection sanatoria are best. But for the purely tuberculous, tuberculin offers in many cases a certain arrest of the disease. Its use should be only in the most careful hands, preferably in institutions, and should not be entrusted to assistants who are frequently changed.

Endolaryngeal Treatment of Cancer of the Larynx.—E. Meyer reports the case of a man aged fifty-eight years, who had complained of husky voice for eight months. A nodular growth was found on the anterior two-thirds of the left vocal cord, which was reddened and congested throughout its whole extent. A projecting process of the tumor overhung the right cord toward the anterior commissure, but the cord itself was unaffected. Diagnosis of carcinoma was confirmed by the microscope. Glandular enlargements were not noted. The tumor was removed in eight sittings by means of forceps and curette. The author discusses the advantages and limitations of the endolaryngeal method.

Total Extirpation of a Large Cyst of the Mesentery.—J. Schramm reports the case of a widow aged forty-eight years, from whom he removed a large cyst of the mesentery. Recovery was uneventful. He then discusses the question of the origin of these tumors, and refers to the literature of the subject.

French Journals.

Capillary Emboli Following Injections of Calomel.—A. Renault publishes an instance of embolism following injection for syphilis, and gives the literature briefly of similar instances. From 1891 to 1896 the author made 8,353 injections of thymol-acetate of mercury, and in nine per cent. of these cases the injections were followed by pulmonary phenomena of more or less severity, with subsequent symptoms of hemorrhagic infarctions due to an embolic process. In conclusion he states that we have no means of preventing with certainty the penetration into the blood current of soluble mercurial salts. He calls to mind the fact that calomel, even in fine powder, is composed of particles which show a very appreciable volume under the microscope, and alone may obstruct capillaries of the lungs. He believes that while the soluble mercurial salts are very powerful they should be used only under exceptional circumstances, when life is endangered, and it is necessary to act energetically. Injections should be given only after a careful examination as to the general integrity of the emunctories, while taking all precautions of technique.—*Le Progrès Médical*, December 23, 1890.

The Functions of the Thymus Gland Based upon its Physiology and Pathology.—L. M. Bonner says that the thymus represents, so far as its functions are concerned, a double organ. It is a hæmatopoietic organ, and it is also a gland having an internal secretion. This has a multiplicity of influences, especially in connection with nutrition. Physiology and pathology are in accord in demonstrating that the thymus presents physiological connections with other analogous viscera. There is, in the normal state, an equilibrium between the various internal secretions: when one of these glands is injured, the equilibrium is broken. It is, perhaps, to re-establish it (in any case it is because of this disparity of normal equilibrium) that we see some other vascular gland become hypertrophied. The thymus is, perhaps, that which presents the most frequently, and under the most variety of circumstances, this vicarious hypertrophy.—*Gazette des Hôpitaux*, December 19, 1899.

Stercoræmia Following Delivery.—A. Brindeau relates several cases showing that elevated temperature, not otherwise accounted for, is wrongly attributed to puerperal fever in some instances. There is usually intense headache, absolute anorexia, foul tongue, fetid breath, and tenderness of the abdomen, all of which symptoms are relieved after salines have been given to produce several abundant passages which are usually fetid. The symptoms may come on anywhere from one to fifteen days even in patients whose bowels have appeared to be regular before delivery. The temperature may go up gradually or at one bound. At times the condition is serious, and may prove fatal. Perforation has been reported, while intestinal hemorrhages and ulcerations have been noted.—*Le Bulletin Médical*, December 30, 1899.

The Remote Results of Perineal Urethrostomy, a Clinical Study Based on Twenty-Three Observations.—In a communication to the Academy of Medicine of Paris in 1892, Antonin Poncet described, under the name of perineal urethrostomy, an operation consisting in the creation in the perineum of an artificial meatus in patients with incurable strictures. He now takes a somewhat less favorable view of the results of this operation than he originally held. He reviews twenty-three cases, in seven of which the stricture returned seven years after the operation; in two, five years; and in two, three years after operation.—*Gazette Hebdomadaire*, December 27, 1899.

Heredity in Chronic Nephritis.—R. Romme relates a family history in which there were eighteen instances of chronic nephritis in three generations. The number of such reports is very rare, there being only five authentic instances in literature.—*Le Progrès Médical*, December 23, 1899.

Respiratory Gymnastics in Pulmonary Tuberculosis.—E. Ripard supplies, with illustrations of the movements, a scheme for giving tone to the respiratory muscles, developing the thoracic cavity, and increasing the breathing capacities.—*Le Progrès Médical*, December 23, 1899.

Vratch, December 11 and 18, 1899.

A Peculiar Disorder of Respiration in Hysteria.—Y. P. Gorshkoff reports a case of hysteria in a soldier, twenty-five years old, who suffered several times a day from laryngeal and diaphragmatic spasms during which respiration was temporarily arrested, all the abdominal muscles were in a tetanoid condition, and several inarticulate expiratory sounds were emitted. The lines of the face were drawn and expressed suffering. Accompanying the respiratory spasm was a tremor in the hypogastric region. There were no special psychical disturbances during these attacks; memory and the reasoning faculty were unchanged, but the patient's spirits seemed a little depressed.

Sanatoria for Consumptives.—S. F. Unterberg treats of sanatoria for tuberculosis and of their educational value. But he says that efforts to prevent infection are not sufficient, that the mere employment of sanitary spittoons will not abolish tuberculosis, and that the most effective means of combating the disease are hygienic and dietetic measures to strengthen the organism. He advocates the adoption of many of the sanatorium regulations in the household, and says that even the nursery should be converted into a domestic sanatorium.

Malarial Insanity.—I. E. Tikanadze reports three cases of this sort, the first of mania, the second of acute confusional insanity, and the third of melancholia recurring with each febrile paroxysm. The author regards as the chief causes of malarial insanity an intensity of infection and a special predisposition, either inherited or acquired. The prognosis is favorable, and the proper treatment is the exhibition of quinine in large doses together with warm baths.

Disinfection with Formaldehyde.—As a result of numerous experiments, together with a review of the literature of the subject, V. A. Levasheff concludes that the disinfectant action of formaldehyde is exerted, ordinarily, chiefly on the surface of objects, and becomes rapidly attenuated from the periphery toward the centre. The best means of destroying the odor of formaldehyde is the employment of ammonium carbonate, which when heated separates into CO_2 and NH_3.

Sclerosis of the Spine.—Under this title M. O. Shaikevitch describes a case of gradually acquired posterior curvature of the dorsal spine, occurring in a man thirty-nine years of age. The actual disease present was somewhat indefinite. There was no spinal caries; the case was not one of rheumatism, although cold seemed to have played the rôle of exciting cause, and the author was inclined to regard it as a diffuse sclerotic affection of the spinal column, first described by Bechterew in 1892.

Thomsen's Disease with Tabes Dorsalis.—S. S. Malbandoff reports a case of myotonia congenita observed in a man twenty-five years of age, who presented also marked symptoms of locomotor ataxia. The patient's brother, eighteen years old, was also a sufferer from Thomsen's disease. He reports briefly also another case of tabes dorsalis combined with myotonia.

Pyramidon and its Therapeutic Uses.—K. I. Korovitski describes this new drug, which is a derivative of pyron, having a formula of $C_{13}H_{17}ON_3$. Its action is similar to that of antipyrin, though more prompt, and as a rule smaller doses are required.

The Dental Division of the Clinical Institute.—A. K. Limberg describes the course of instruction in dentistry given at the Elena Pavlovna Clinical Institute at St. Petersburg.

The Crusade against Consumption.—I. N. Lange enters a plea for the use of tuberculin in cattle as a protection to man.

Jour. of Cutan. and Genito-Urinary Dis., January, 1900.

A Case of Macular Lepride of the Scalp, with Remarks on the Localization of Leprous Lesions.—Prince A. Morrow says that a curious fact about leprosy is that the two principal forms, although etiologically identical, show marked differences in character of the cutaneous lesions, and also in their localization. It may be said that the erythematous patches of the tubercular form are transient in duration and may disappear and reappear a number of times before becoming the seat of tubercular infiltrations, while those of the anæsthetic form are essentially permanent. The case reported is unique in so far as it is the only one which the author has found recorded presenting a macular lepride of the scalp. The distribution of the eruption over the cheek and forehead, extending into the hairy scalp, is shown in the illustration.

The Urethroscope in the Treatment of Strictures.—Henry Koch relates a case showing that the present urethroscope with heatless light is not only an instrument for diagnosis, but can be used for other and very important practical purposes for which the endoscope could not be used. The tube used in the case related differed from others so far constructed by having the lamp carrier and lamp held separately in a small tube under the larger endoscopic tube proper. Light is thrown through the opening on the surface to be illuminated.

The Etiology and Rational Treatment of Urethro-Arthritis and Allied Affections.—A. MacKenzie Forbes says that urethral arthritis is due either to the migration of the gonococcus or some other microbic habitant of the urethra to the joints, or to the absorption of the toxins eliminated by these habitants. To effect a cure the urethra must be kept as absolutely sterile as it is possible to keep that canal, and its mucosa must be without abrasion. Notes of cases are given.

A Case of Blastomycetic Dermatitis Engrafted on Syphilitic Ulceration.—Henry G. Antony and Maximilian Herzog report the case of a patient who had suffered from extensive ulcerations for twenty years, which were distinctly syphilitic in character, being of the type of syphilis cutanea vegetans. After staining sections of the tissues blastomycetes were found. Under iodide of potassium in large doses marked improvement occurred.

St. Louis Courier of Medicine, December, 1899.

Complete Inversion of the Uterus from Fibroids; Vaginal Hysterectomy; Recovery.—Henry H. Mudd, in the last contribution of his life to medical literature, reports a successful operation for the rare condition of total inversion in a non-puerperal uterus. After operation interstitial fibroids were found. The Rotunda Hospital had but one instance of acute inversion in one hundred and ninety thousand births; at St. Petersburg this complication did not occur in two hundred thousand nor in Vienna in two hundred and fifty thousand deliveries.

Suprapubic Prostatectomy.—A. E. Rockey says operations for enlarged prostate by sexual mutilation have failed so often that they are to be condemned. He has evolved from McGill's method one of his own—a combined morcellation, enucleation, and evulsion through a short suprapubic incision, with an assistant's finger in the rectum raising the gland. He has been satisfied with suprapubic drainage. Opening the bladder when symptoms warrant is preferable to attempts at fine diagnosis beforehand.

Some Phases of Lues in Early Life.—Charles W. Allen relates several instances of infantile syphilis evidently of congenital origin, in which evidences of the disease could not be found in the parents. The acquired disease of unexplained origin was also found in young children. In one of the instances of family syphilis recorded, an infant contracted the disease from a wetnurse, and inoculated the mother, who in turn infected the father and at least one other child.

Beef-Gall Enemata in the Treatment of Post-Operative and Intestinal Obstruction.—F. C. Ameiss recommends fresh bile enemata (four cases), claiming that, aside from mechanical effect, absorption of bile salts acts as an exciter of cholagogue action. Reopening the abdomen is not always advisable.

Indications for Cæsarean Section, Symphyseotomy, Craniotomy, and Induced Premature Labor.—By Leopold. See MEDICAL RECORD, vol. lvi., p. 497.

Archives of Pediatrics, January, 1900.

A Clinical Study of Laboratory Milk in Substitute Infant Feeding.—Louis Starr declares that although laboratory milk is theoretically the most perfect substitute for normal human milk now known, this theory is not upheld by clinical experience. He does not absolutely condemn this milk, for its introduction has called attention to the importance of cleanliness and accuracy in the quantity and chemical composition of cow's milk foods. It is also of great use in feeding infants who must be artificially nourished from birth, and may often be used with advantage to the end of the second month. However, its applicability is limited, and much more so than the process of modification in which unseparated milk is employed.

Cerebro-Spinal Symptoms in Influenza in Infancy.—Thompson S. Westcott reports two such cases. This condition has been described as pseudo-meningitis grippalis, and simulates meningitis in every particular, but in the event of death it shows at the most hyperæmia of the pia and brain, or a permeation of these parts with serum.

A Case of Fracture of the Pelvis with Rupture of the Urethra.—Joseph B. Bissell reports this case, of a boy aged nine years, and believes the favorable result to be due to the youth and good health of the patient, and to early incision, perfect drainage, and simplicity of technique.

The Practitioner, December, 1899, and January, 1900.

The Relationship of Membranous Inflammation of the Nose to Diphtheria.—Eugene S. Yonge defines membranous rhinitis as a subacute or chronic affection of the nose, characterized by a fibrinous or membranous exudation on the mucous membrane of one or both nares. The deeper tissues are not, as a rule, involved, and the membrane rarely extends to the throat. The course may exceed eight weeks. The Klebs-Loeffler bacillus in various degrees of virulence is found in the majority of instances. The disease in both children and adults may be ushered in by chilly sensations or more rarely by a definite rigor, which is soon followed by a general febrile condition. Symptoms of acute rhinitis rapidly supervene. The dry stage is omitted, and the discharge begins at once. In three days a membrane will have formed. Nasal stenosis becomes severe and is associated with headache and loss of smell. The thermometer registers 101° to 103° F., but falls to 100° or 101° F. in a day or two, and in children remains at this point during the entire attack of three to six weeks. The clinical course does not seem altered by the fact of the presence or absence of the Klebs-Loeffler bacillus, while true primary diphtheria of the nose, which is rare, runs a very malignant course.

Mongolian Imbecility in Infants.—G. A. Sutherland says that subjects of Mongolian or Kalmuc idiocy usually drift into asylums if they survive long enough. Mental and physical characteristics easily distinguish them from normal infants. Their resemblance to one another is very striking. Growth proceeds at a slow rate. Antero-posterior shortening of the skull may render the face and occipital regions flat. The fontanelle is large and slow in closing. The mouth is usually kept open, and the tongue often protrudes and there may be a habit of drawing it in with a smacking noise. The abdomen is large and distended. Intelligence lags; the infant usually requires no attention through excess of "goodness." Dentition is much delayed, while muscular power and co-ordination are slowly acquired. There is strong predisposition to disease and to early death. The thymus, thyroid, and suprarenals are structurally healthy, and treatment by the extract of thymus and thyroid has proven useless; treatment in the absence of any known cure must be general and symptomatic.

The Operative Treatment of Fibroids.—In a clinical lecture, delivered by G. E. Herman, the reasons pointed out for operating are: First, hemorrhage sufficient to weaken the patient, which is not brought under control by ergot and similar drugs. Secondly, size, making the patient unwieldy or bedridden; or the tumor may be relatively large in relation to the space in which it lies, and may press upon adjacent parts, causing symptoms which warrant operation. Thirdly, a fibroid may rapidly increase in size, indicating that the tumor is degenerating, or is a sarcoma rather than a fibroid. The best operation is one which removes the tumor without taking away anything else. One advantage of the vaginal over the abdominal route is that it is easier to separate the ureters from the bladder from below than it is from above. Vaginal treatment is only appropriate, however, when the tumor is not larger than a child's head and can be pressed down into the pelvis. The electrical treatment is looked upon as now almost extinct.

Temporo-Maxillary Ankylosis, and its Relief by Excision of the Neck and Condyle of the Lower Jaw.—David M. Greig claims that the results of operation in temporo-maxillary ankylosis are eminently satisfactory, the muscles, after years of disease, reassuming their functions almost at once. The causes are traumatic or non-traumatic. The first are extra-articular or intra-articular; the second suppurative or non-suppurative. Cases and illustrations are given.

Affections of the Cornea.—Marcus Gunn calls attention to the anatomy of the cornea and the especial clinical importance of the smoothness of its anterior surface and its transparency, the latter being due to the disposition of the lamellæ of fibrous tissue. Disease of the cornea may be recognized by lack of one of these qualities.

Pneumonia.—Sir William Broadbent treats of the etiology, symptoms, signs, prognosis, and treatment. From time to time the pneumococci seem to acquire a degree of virulence which renders the disease contagious, causing epidemics. Apparently the diplococci are carried about in the mouth and pharnyx. Should the crisis not have come by about the ninth day it may be concluded that there is some underlying cause such as tubercle or septicæmia. Unabsorbed pneumonic deposits are practically unknown post mortem. Catarrhal pneumonia is the form which complicates measles and pertussis, or, later in life, may supervene upon bronchitis. No definite line can be drawn between the catarrh of the finer bronchial tubes and broncho-pneumonia. The temperature is not a source of danger. We can afford to wait. Antipyretic drugs given continuously are not only useless but dangerous, and in exceptional cases a considerable amount of spirits, such as brandy in champagne, may be given. For the persistent sleeplessness morphine should be given, especially if there is delirium. Venesection is advisable when the right ventricle is unable to cope with the constant resistance in the pulmonary circulation, and is paralyzed by over-distention. There are cyanosis, turgid temples, small and short pulse. The pulse improves and the breathing is relieved when sixteen to twenty ounces of blood have been taken.

Pneumonia from a Public-Health Standpoint.—Arthur Newsholme says it is clear that the heaviest rate of mortality falls in the earliest, and the next heaviest in the last, years of life. He considers questions of transference between pneumonia and phthisis and bronchitis, and the influence of seasons, weather, race, occupation, and epidemics of pneumonia. Hirsch's statistics show that the largest number of cases occur from February to May. He maintains that the death rate rises to its maximum in December. It is a cold-weather disease. This by no means disproves its specific febrile character. Iron-workers and coal-heavers give the largest percentage of cases, lock laborers the next, then hotel servants, cabmen, and innkeepers. Doctors and musicians stand an equal chance. The history of many localized outbreaks favors the idea of a direct infectivity. Cases are cited showing exceptionally direct personal infection due to overcrowding, defective house sanitation, etc., which accounted for certain epidemics.

Etiology and Symptomatology of Goitre.—J. G. Adami reviews at length the whole question of the cause of goitre, especially as it concerns the island of Montreal. In some French Canadian villages scarcely a family is to be found without one or more goitrous members. It is generally accepted that weather has to do with its development, but how it does so is absolutely unknown. In favor of the infective origin not a few facts have been brought forward. In one instance one thousand and nine soldiers of a regiment, whose quarters had been changed to a goitrous region, became affected. Lustic and Carrele found a bacillus constantly present in goitrous waters. If the individual is removed from the goitrous region sufficiently early, the tendency is for the enlargement to disappear.

The Mortality and Frequency of Pneumonia as Affected by Age, Sex, Seasons, and Habits.—Hector Mackenzie says that pneumonia causes very nearly as many deaths as typhoid fever, diphtheria, smallpox, measles, and scarlet fever together. Deaths from pneumonia amount to 5.6 per cent. of the total number of deaths from all causes. In males between the ages of twenty-five and sixty-five years, eight per cent. of all deaths are due to this disease. Alcoholism appears to diminish the chances of recovery. A history of rheumatism is to be obtained in about six per cent. of the cases, and pericarditis occurs in about twelve per cent. of the fatal cases.

The Treatment of Pneumonia.—Sir William Gairdner reviews old methods and dwells upon historical and personal matters. Antimony and blood-letting are valuable in very exceptional cases. His treatment is mainly expectant. Opium he considers a dangerous remedy, especially about the period of crisis, having a tendency to increase the cyanosis, there being practically a paralyzing action upon the respiratory centres.

The Journal of Tropical Medicine, December, 1899.

Possible Causes of Sickness among the British Troops in South Africa.—In the present instalment of a continued article, L. W. Sambon discusses bilharzia disease, or endemic hæmaturia, and the plague. The true endemic region of plague, he says, is in Thibet, whence it makes incursions into China, India, and Persia. He regards fleas as the chief conveyers of the disease from rat to rat, from rat to man, and from man to man.

A Case of Parasitic Hæmoptysis.—J. Preston Maxwell reports the case of a man, sixty-four years old, who suffered from occasional attacks of hæmoptysis. There were no signs of tuberculosis. The blood coughed up contained many ova, which, however, the author did not succeed in hatching. The administration of thymol and santonin was followed by the passage from the bowels of about fifty round worms.

Malaria and Anopheles in Lagos, West Africa.—Henry Strachan discusses, from the point of view of his experiences in West Africa, the relation of mosquitoes and malaria, and mentions several points of distinction between Anopheles and Culex in both the larval and the imago stages.

Further Results of Haffkine's Anti-Cholera Inoculation.—Arthur Powell presents some statistics of cholera inoculations in nine estates and villages in India. There were 198 cases with 24 deaths among 6,549 not inoculated, and but 27 cases with 14 deaths among 5,778 inoculated.

On Tropical Anæmia and its Relation to the Latent and to the Manifest Forms of Malarial Infection.—This is an instalment of a continued article by F. Plehn of Kamerun.

Edinburgh Medical Journal, January, 1900.

The Infectivity of Malignant Growths.—G. Bellingham Smith holds from experimental research that these growths are local in origin, possessing the power of affecting adjacent and distant parts; that inoculation may take place from one part to another of the individual, apart from transference by the natural channels; that one individual may be infected with growth from another; that growths may be transferred from animal to animal of the same species by inoculation. There have been found in many malignant growths bodies resembling micro-organisms, which are regarded as either protozoa or blastomycetes. A new growth with the structure and behavior of carcinoma has twice arisen from inoculation with a form of blastomyces. The experiments suggest that the bodies found in cancer cause the disease.

Febrile Albuminuria.—F. Parkes Weber prefers the term "rheumatic albuminuria" to that of "febrile albuminuria" in cases of rheumatism accompanied by albuminuria, because he thinks it cannot be maintained that the symptom is caused merely by pyrexia. It is much more likely that in most cases it is due to the causes of the pyrexia—to the presence of irritants in the kidneys or from a toxæmic condition of the blood, and such toxæmic conditions of the blood may be due to infectious (microbic) causes or may be the result of any kind of abnormal tissue change in the body.

Some Observations on the Excretion of Uric Acid, with Especial Reference to its Connection with Leucocytes.—Carstairs C. Douglas from clinical studies concludes that there is a discrepancy between the amount of uric acid thrown off from the body and the number of leucocytes. That nuclein containing tissues or ingestion may increase the amount of uric acid excreted is proved by experimentation, but the observations made do not support the view that normally the source of uric acid is to be found in the nuclein of the leucocytes.

Urinary Calculus.—George Buchanan reports a case of calculus which was impacted in the prostatic urethra, and was removed by perineal section. It measured two and one-fourth by one and three-fourths by one and three-fourths inches.

Purulent Ophthalmia.—A. Maitland Ramsay considers nitrate of silver the best remedy, so long as there is much secretion; when the discharge lessens this should be replaced by sulphate of copper.

Dysentery as it Occurs in Fiji.—Charles T. W. Hirsch says that dysentery is endemic, and occurs among the European settlers, natives, and Indians, and Polynesian immigrants in May, June, and July.

Canadian Journal of Medicine and Surgery, Jan., 1900.

The Hospital Room in Each Dwelling.—W. J. Telfer describes the advantages of the home hospital room. This apartment should be the favorite one when there is no sickness in the family; nevertheless, when occasion arises, it may in half an hour be changed into a more or less complete hospital. The ceiling, walls, and floor must be finished so that they can be washed clean. The furniture should be such as to be readily rendered aseptic. Water and toilet adjuncts should be at hand. A special bath and water-closet should be accessible; movable substitutes could be used in the country. When isolation is imperative either the front or back entrance may be temporarily monopolized by the patient's attendants.

Anæsthesia by Chloroform and Ether.—William B. Jones emphasizes the importance of employing a skilled anæsthetist. He should be acquainted with the patient's history and present condition. The right stage of narcosis must be obtained under all circumstances, the least possible amount of ether or chloroform being used. The hue of the face tells more than the pulse as to the condition of the circulation. The pupils should be almost continually watched, they being the best index of the patient's condition.

Cases of Puerperal Sepsis Treated with Antistreptococcus Serum, with Notes.—George T. McKeough, after noting several cases of this nature, declares that, although the reports of the use of the serum are conflicting, and possibly not very encouraging, yet it exerts no pernicious effects and does merit a continued use.

The History of Medicine.—Ezra H. B. Stafford states that the history of medicine teaches the unity of aim, the singleness of purpose, the undeviating allegiance to an unchanging ideal through long ages, that can be claimed by no other art, no other fraternity.

The Treatment of the Acute Digestive Disorders of Infancy.—By Andrew R. Gordon. See MEDICAL RECORD, vol. lvi., p. 424.

Monatsschrift für Geburts. und Gynäk., December, 1899.

The Clinical Significance of Retroversion of a Movable Uterus.—B. Krönig and J. Feuchtwanger assert that since we accept Schultze's teaching that anteversion of the movable uterus is its normal position, we must admit that retroversion is a pathological condition. Symptoms of retroversion are both local and general. The more or less localized symptoms are profuse menstruation, dysmenorrhœa, backache, abdominal pain, and "bearing down" sensations. Among the general symptoms are dyspepsia, vomiting, meteorism, palpitation, and headache. Some authorities believe that retroflexion should not be treated unless it is accompanied by troublesome symptoms, while others believe in treatment as soon as the condition is discovered, even if no symptoms present themselves.

Pseudo-Myxoma of the Peritoneum.—C. Peters states that Werth in 1884 defined pseudo-myxoma of the peritoneum as a peculiar affection which often made its appearance after the bursting of a pseudomucinous cystoma. He notes as most worthy of mention, in several cases which he reports, the complication of metastases, which frequently occur after the spontaneous rupture of pseudo-mucinous cystomata or from the soiling of the abdominal cavity by the cyst contents during operation. The prognosis is not very good. A perfect cure cannot be claimed till the patient has remained free from recurrence for a year.

The Influence of Sugar on Metabolism in Pregnancy and Labor.—Adolf Payer comes to the conclusion on this subject that small quantities of sugar (30–60 gm.) given once, or several times, increase uterine contractions and hasten labor, especially in its initial stage. The whole course of labor is influenced by the administration of a large dose (100–130 gm.) before it begins. Sugar has a sedative influence on labor pains. For all these purposes sugar may be recommended.

A Metal Instrument as a Substitute for the Balloon in Cervix Dilatation.—Schwarzenbach describes an instrument for dilating the cervix in pregnancy, called the "tulip." It is used to induce premature labor; also in the course of labor coming on at the usual time when pains grow weak and other measures fail.

Ovarian Tumors Arising from the Origin of Accessory Supra-Renals.—Heinrich Peham gives a résumé of his work on these tumors, including a careful microscopical study of the tissue.

Monatsberichte für Harn- und Sexual-Apparate, December, 1899.

Lubricants for Urological Instruments.—Felix Schlagintweit calls attention to the difficulty of keeping ordinary fatty lubricants sterile, and the further difficulty of removing them from instruments after use. They are likewise often destructive to the prism of the cystoscope. Glycerin has the disadvantage of exciting a watery flow from the mucous membrane of the canal, which interferes with instruments of observation. Finding an objection to almost all soapy and other substitutes advocated, he has at last settled upon the one recommended by Guyon: Gum tragacanth, 2.5; glycerin, 10; carbolic solution (three per cent.), 90; this he encloses in tubes which have been previously sterilized.

Annales des Maladies des Organes Génito-Urinaires, December, 1899.

Impotence in Man.—J. Zabludowski, in discussing the treatment of impotence, shows that the bed of the patient who suffers from pollutions should be changed; he should be made to sleep on the sofa instead of the bed. He should also take up some unusual bodily exercise. In a very obstinate case, in which the disease had lasted more than twenty years, a good result was obtained by advising the patient to wear a condom, instead of bathing-trunks which he was in the habit of wearing at night to prevent soiling the bed linen. The pollutions ceased at once. These patients should also be advised not to take their habitual drink at night, and to change their dining-hour. Patients who suffer from spermatorrhœa, and who give a history of having practised interrupted coitus, as well as those who suffer from prostatorrhœa, being often subjects of posterior urethritis, should be given massage of the prostate and abdomen, and be advised to avoid interrupted coitus. In cases of general depression following violent emotions, excellent results have been obtained by general massage, especially dorsal tapotement. This variety of massage will take the place of a strict régime in cases complicated by diabetes or general obesity. It is absolutely necessary to give a good prognosis from the start, especially to candidates for marriage, who do not dare to enter into the contract because of previous experiences. In cases complicated with difficulties of urination, the whole attention should be directed to the prostate, perineum, and bladder. As an aid to general treatment, the whole make up of the bed should be changed, especially in the coverings and draperies, etc., to impress the mind.

Etiology of Infectious Cystitis.—R. P. Van Calcar concludes, as the result of his researches, that, in a large number of cases of infectious cystitis, the infection has not taken place from without by way of the urethra, but directly from the intestine, not by way of the kidney or through the circulation. It is very probable that the microbes follow the subperitoneal route. The chief predisposing conditions are retention and dilatation of the bladder. These conclusions are based upon the following facts: (1) The organisms which are found in cases of cystitis differ completely, as a rule, from those which we find in the urethra. (2) The urethra, be it diseased or healthy, is most sterile for the special organism of cystitis, the bacterium coli communis. (3) In circumstances predisposing to cystitis the microbes of the urethra show no tendency to ascend. (4) The microbes of cystitis, at least the chief ones among them, are found pre-existing in the intestine. (5) The presence of microbes, which, under the influence of pathological conditions, infect the bladder from the intestine, is revealed in this organ sooner than in the urine from the ureters.

Treatment of Prostatic Suppurations.—F. P. Guiard, after reviewing the various methods of surgical treatment of prostatic suppurations, gives his experience in puncturing with a trocar through the rectal wall, followed by antiseptic washings, and gives the special technique for incision under the eye and for applying the ligature in cases of hemorrhage. He believes that puncture, followed by antiseptic lavage, could be applied to various suppurations more or less deeply situated, so as to do away with the more serious operations, and he questions whether it should not be attempted in regions where it is desirable to avoid disfiguring cicatrices.

Revue de Médecine, December, 1899.

Malarial Infection and Epilepsy.—Marandon de Montyel, while not in opposition to the recent theory that, the infectious diseases exercising a beneficial action upon epilepsy, the latter may be cured or modified by inoculation with the germs of various maladies, believes that infection is a two-edged sword, and that its influence is not always beneficial, but sometimes indeed injurious. Malaria has by some authorities been held to be a sovereign remedy, so that they had advised the construction of epileptic hospitals in malarial regions, or the sending of epileptics to malarial districts, with the view of substituting the latter disease for the former and then curing it by the administration of quinine. The author reports fourteen cases in which malaria distinctly aggravated the epilepsy, or caused a return of attacks which had long been absent, or even induced attacks for the first time in some neuropathic patients. Therefore he thinks that caution should be exercised in the treatment of epilepsy by other infections, although it is very possible that in some cases the influence exercised might be a beneficial one.

The Sonorousness of the Abdomen.—De Sigaud says, in regard to the tympanitic sounds, that they consist (1) of a simple initial sound produced by the vibrations of the sonorous membrane; (2) harmonic sounds superadded to the first, and giving it its volume and characteristic tone. There are four varieties of tympanitic sound: sharp, amphoric, deep, and cavernous. The tone varies with the dimensions of the resonant cavity—the sharp tone corresponding to the minimum capacity and the cavernous to the maximum capacity. There are other and perhaps more important factors in the production of the sound, but as yet we are not familiar with them.

Exophthalmic Goitre.—Edouard Boinet says that the complex pathogenesis of this disease and that of diabetes offer many resemblances. Just as the overactivity of the liver in diabetes proceeds from the central nervous system, so are the hypersecretion of the thyroid gland and the dilatation of its vessels, of the base of the neck, and the retro-ocular tissue usually dependent upon an initial stimulation of the Basedowian centres. Later, a secondary thyroid intoxication may occasion the series of Basedow symptoms of toxic origin, and even react upon the nerve centres.

Cracked-Pot Resonance.—Fr. Duplant reports facts from which he concludes that this form of resonance is produced in pulmonary cavities: (1) When there is a large superficial cavity containing much air and communicating with a bronchus; (2) when a deep cavity is separated from the thoracic wall by indurated parenchyma; (3) when a small, superficial cavity containing little air and communicating but slightly with the bronchi is situated within resistant tissue, such as hepatized lung tissue.

Stomatitis and Pseudo-Membranous Angina.—Vincent Griffon reports a case which occurred in a patient suffering from pneumonia accompanied by a typhoid state, in which, thanks to serum diagnosis, the pneumococci were found in the early stages.

Revue de Chirurgie, December 10, 1899.

Intralaryngeal Cysts.—E. Louys says that these growths are usually benign, but the great sensitiveness of the organ in which they are situated, the delicacy of action of the apparatus of phonation, and the necessity of free aperture of the larynx for respiration render them of importance. The author believes that many of these cysts are of embryonic origin, some of them being branchial, some proceeding from the lateral lobe of the thyroid gland, and some from the thyro-lingual duct. The symptoms of these cysts are those of any foreign body—dyspnœa, dysphonia, sometimes accompanied by pain and cough. Indirect treatment consists in the use of revulsives to the neck, these acting upon the symptoms of laryngitis to which the cyst may give rise, or in the use of medicated inhalations or of mineral waters. Direct treatment may consist of endolaryngeal puncture alone, or with aspiration, or incision and excision of portions of the laryngeal wall. The galvanic cautery is sometimes efficacious. Laryngotomy is the operation to be preferred, and can best be performed under local anæsthesia by cocaine.

The Infection and Disinfection of Wounds due to Fire-Arms.—E. Tavel's experiments upon rabbits, described at great length, lead to the conclusion that a masterly inactivity is apparently the best treatment for wounds by contaminated missiles. Iodoform gauze he found to be not very harmful, retarding recovery by only six days, while glass drainage tubes caused a delay of sixteen days. Disinfection of the wounds is impracticable as a rule, and the chemical or physical means employed for the purpose merely serve further to injure the tissues and put them in a condition to be invaded by the microbes carried into the wound by the ball.

Abdominal Hysterectomy.—F. Terrier reports fifty-nine operations performed by him during the past year, with a mortality of 8.47 per cent. His preference is for total hysterectomy when practicable.

Inguino - Scrotal Lymphangioma. — Brant Paes Leme reports a case in which embryonic filaria sanguinis hominis, although not found in sections of the tumor, were found in the patient's blood.

Reviews and Notices.

TREATMENT OF SKIN CANCERS. By DR. W. S. GOTTHEIL. International Journal of Surgery, New York, 1899.

A SMALL book, in which is briefly reviewed the etiology, pathology, diagnosis, and treatment of cutaneous carcinomata. The author dwells especially, in his chapter on treatment, on the value of caustics for the radical cure of skin cancers. He fails, however, to indicate to what particular types of these malignant new growths caustics are more applicable than is excision.

LECTURES UPON THE PRINCIPLES OF SURGERY, delivered at the University of Michigan. By C. B. Nancrede, A.M., M.D., etc.; with an Appendix containing a *Résumé* of the Principal Views held concerning Inflammation, by W. A. SPITZLEY, A.B., M.D., etc. Illustrated. Philadelphia: W. B. Saunders. 1899.

THIS volume contains the lectures of the author, as given at the University of Michigan, upon the subject of the title. There is no pretence that the book is any more than a collection of lectures, so that we may expect and understand a certain amount of lack of continuity. The subjects are discussed interestingly, though we cannot say that anything novel or particularly worthy of comment is offered. The students who come under the immediate supervision of the author will undoubtedly find the book a very valuable one, and we suppose that it is intended primarily for their use as a text-book in connection with didactic lectures.

LEHRBUCH DER KINDERKRANKHEITEN FÜR AERZTE UND STUDIRENDE. Von DR. ADOLPH BAGINSKY, a. o. Professor of Diseases of Children in the Berlin University, and Director of the Kaiser und Kaiserin Friedrich Children's Hospital. Sixth improved and enlarged edition. In two parts. Braunschweig: Published by Fried. Wredn. 1899.

THIS new edition, consisting of over one thousand pages, has just appeared in two volumes. Part I. commences with the description of the physiological functions of an infant, mentions the growth and development of a child, and then enters into the details pertaining to infant feeding—both artificial and natural methods. Whoever has followed the previous publications of Baginsky will be greatly impressed with this chapter, which we consider the most vital and valuable in the new edition. To begin, the author does not only ignore the most recent publications of Heubner, but discards the theories of that writer. Baginsky is emphatic in his assertions that we must recognize the value of studying each child individually and responding to the individual needs of children. Some children will thrive on a given feeding which is wholly inadequate for another child of the same age. He emphasizes the value of examining the fæces, quoting Escherich in this regard. Speaking of the decomposition of milk, particularly in summer, the author calls attention to the dangers by the formation of poisonous peptone bodies which he calls "pepto-toxins." His deductions are based on personal observations in the nursling pavilion. Next follows the description of the usual methods of examining a sick child in making a diagnosis, and all the diseases of the new-born are detailed. Following this chapter we are brought into the description of the eruptive (exanthematous) disorders. All typhoid lesions are thoroughly described, and every detail pertaining to the diagnosis, pathology, and especial therapeutic management is carefully considered. In mentioning the general infections like diphtheria we ask: "Who is more competent than Baginsky to speak on serum therapeutics, and to whom is the profession of the whole world more indebted than to this author for disseminating the true status pertaining to the value of antitoxin?" In reading the author's views on tuberculosis we cannot but call the chapter a masterpiece. The chapters on cerebral and, in fact, all diseases of the nervous system are complete in every detail, based as they are on studies in which anatomical and pathological details are considered. It is interesting to note *en passant* that although the author is one of the first to attach to bacteriology its true value from an etiological standpoint, he does not believe that, when we are not absolutely positive, all pathological conditions must be included and compelled to conform to either (1) specificity, (2) infection, (3) sepsis. The author believes that other agents equally important are frequently at work and deserve distinct etiological recognition. Based as this work is on the experience of one of the largest children's hospitals in the world, with a very large staff of assistants in the various departments, we have the latest wrinkles, views, and therapeutics in pædiatrics. The work appeals to every one desiring a complete insight into any and all details of the diseases of children.

TRANSACTIONS OF THE ASSOCIATION OF AMERICAN PHYSICIANS. Vol. XIV., 1899. 8vo, pp. 366.

THIS is an unusually interesting volume of its series, which is saying a great deal for the general excellence and practical value of its contents. The papers contributed by the members are on practical subjects, are exhaustively treated, and well selected.

LECTURES ON TUMORS. By JOHN B. HAMILTON, M.D., LL.D., Professor of Surgery, Rush Medical College, Chicago. Third edition. Philadelphia: P. Blakiston's Sons & Co. 1899. Pp. 143.

THE third edition of this work comes in its original form. In a condensed and lucid manner it treats of morbid growths in all their bearings, and is in all respects a practical book for the student and practitioner.

TRANSACTIONS OF THE AMERICAN GYNÆCOLOGICAL SOCIETY. Vol. XXIV., for the year 1899. 8vo, pp. 520.

THIS volume contains a large number of monographs on all the more recent gynæcological operations, numbering nearly thirty in all. The reader cannot fail to notice that in all the operative manœuvres advocated there is a disposition to conservatism which is in striking contrast to gynæcological practice years ago. Radical methods are being replaced by simpler ones, and altogether gynæcology is making rapid strides along rational lines.

DEAVER'S SURGICAL ANATOMY: A Treatise on Human Anatomy in its application to the Practice of Medicine and Surgery. By JOHN B. DEAVER, M.D., Surgeon-in-Chief to the German Hospital, Philadelphia. In three royal octavo volumes. Volume I. Philadelphia: P. Blakiston's Son & Co. Royal octavo, pp. 632.

THE author informs us in his preface that his work, the first instalment of which appears in the present volume, has occupied his earnest thought for twelve years. To say that the time has been well spent is perhaps sufficient commendation in a general way. In many respects the plan and scope of the book are unique, and follow the intention of the author in representing what a model and practical treatise on applied anatomy should be, not only for the surgeon but for the every-day practitioner as well. To the former the numerous and finely executed plates, representing superficial and deep anatomy, with their accurate regional relations, it will serve as an ever-ready and reliable guide in times of emergencies, when cadavers are beyond reach, and where there are no similar means for refreshing the memory; while to the busy physician abundant opportunities are afforded for readily acquainting himself with "every phase of anatomy superficial or deep, as applied to disease, and the most modern methods of treatment of injuries." The first volume of this remarkably elaborate and profusely illustrated work treats of the upper extremity, back of the neck, shoulder, trunk, cranium, scalp, and face. The reader is not only taken by easy and natural stages from the more superficial to the deeper regions, but the various important regional landmarks are also indicated by schematic tracing upon the limbs. Thus the course of arteries, veins, and nerves are indicated in a way that makes the lesson strikingly impressive and easily learned. No expense, evidently, has been spared in the preparation of the work, judging from the number of full-page plates it contains, not counting the smaller drawings. Most of these have been "drawn by special artists from dissections made for the purpose in the dissecting-rooms of the University of Pennsylvania." In summing up the general excellences of this remarkable work, we can accord our unqualified praise for the accurate, exhaustive, and systematic manner in which the author has carried out his plan, and we can commend it as a model of its kind, which must be possessed to be appreciated.

Society Reports.

THE MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, January 8, 1900.

AUSTIN FLINT, M.D., IN THE CHAIR.

Report of a Case of Properitoneal (Interstitial) Hernia.—DR. L. GRANT BALDWIN reported this case. On December 10, 1899, Mrs. B—— was referred to his service at St. Peter's Hospital with a probable diagnosis of intestinal obstruction. She was thirty-eight years of age, had never borne children, and her previous health had always been good. On admission the patient stated that five days previous she was compelled to go to bed on account of a feeling of nausea, but this was relieved by the use of home remedies, and the next day she was able to be up. Two days later, December 7th, she was seized with severe vomiting, which continued until her admission into the hospital; the vomiting was very severe and was accompanied by marked abdominal pains, chiefly located in the epigastrium. The vomiting at no time became fecal, and was constant except when the patient was under the influence of morphine. The bowels last moved on the morning of the 5th. On admission to the hospital the pulse was 130; temperature, 99° F. There was no abdominal distention, and doubts were entertained as to the case being one of intestinal obstruction. Abdominal examination revealed nothing definite. Hot saline solution was administered by the mouth, as were copious enemata. Six hours after admission there was felt a small lump in the left inguinal region about an inch and a half above Poupart's ligament. It first gave the impression of a distended Fallopian tube that had become adherent to the parietal peritoneum; there was only the slightest ocular evidence of swelling. Bimanual examination eliminated tubal or ovarian trouble, so it was learned that the tumor was intestine. There seemed to be no doubt whatever that the hernia was incomplete, and was interstitial. Operation on the following morning confirmed the diagnosis. The internal ring was displaced upward and toward the median line. The tumor, which consisted of a coil of small intestine with some serous fluid, was not larger than half of an English walnut; it had come through the peritoneum and struck the transversalis muscle at least three-quarters of an inch above its lower border or the ordinary location of the internal ring, and then was deflected inward almost to the border of the rectus muscle. The fleshy part of the transversalis muscle was cut for a distance of an inch and the constriction relieved from without inward. The sac was opened and the constriction was found to be absolute and complete, yet the entire calibre of the gut was not through the opening, the constriction being complete by the sharp bend rather than by the involvement of the whole gut. The sac was cut off flush and stitched carefully with catgut. This having been done and the parts being allowed to resume their natural relations, the internal ring with its contents was the full width of the hernial opening below and external to it. A modified Bassini was done, and convalescence was uninterrupted. The chief point of interest seemed to be the ease with which the true condition might have been overlooked, and a diagnosis not made in time to save the patient's life. A median abdominal section done in search of the cause of the obstipation might not have located the trouble. All cases hitherto reported have been in males, and have been very generally due to an undescended testicle.

DR. WILLIAM B. DE GARMO mentioned a case of a woman, aged seventy-six years, seen by him two years ago, who had a properitoneal hernia probably due to the wearing of a poorly fitting truss. She, too, had symptoms of intestinal obstruction, but the tumor could be felt. A loop of intestine was found to be strangulated under the transversalis fascia. There was a pocket extending almost to the median line.

The Etiology and Treatment of Acne Vulgaris.—DR. ROBERT ALFRED SANDS read this paper. Published statistics showed that this name included about eight per cent. of all skin diseases. What was acne? There were no less than seventeen distinct diseases included under this term of acne. Unna claimed that the term meant nothing definite. He stated that "it is a disease of the skin limited to the cheek, nose, forehead, chin, and shoulders, and to the period of puberty. It rarely extends to the whole back, still more rarely to other parts of the body, and usually disappears with adolescence. It is characterized in the first stage by a superficial hyperkeratosis of the epidermis, which, extending to the follicular mouths, leads to the formation of comedones. While the sebaceous glands with the follicles are stopped with horny plugs, the coil glands are active; indeed there is often hyperidrosis oleosa. . . . On this basis a more inflammatory development of the disease takes place in two directions, one progressive, dry, and inflammatory, with thickening of the whole skin, hypertrophy of the sebaceous glands, and formation of the inflammatory nodes (acne indurata), the other accompanied by secondary suppuration of the sebaceous glands (acne pustulosa)."

Constitutional Causes Favoring the Formation of Acne.—Text-books led one to infer that acne was a local manifestation of a general systemic disturbance, such as anæmia, dyspepsia, constipation, and derangements of the genito-urinary apparatus, etc. Some even believed that it was a disease of the blood. The speaker disagreed with this. A careful analysis of five hundred cases of acne showed that seventy per cent. were free from constipation. He had noted the fact that patients did not develop new lesions during the menstrual period with any greater frequency than during the intervals, although many complained that the pre-existing nodules became somewhat more tender. The point he wished to emphasize was that while possibly an acne already in existence might be slightly modified by the health of other organs, the relationship between the two was so slight that one could disregard it in the treatment.

External Treatment.—First, asepsis, which meant a separate soap for the face, a separate rag for the face, washing the hands prior to washing the face, and a nightly changing of the pillow in the case of patients having much pustulation. The patients must keep their hands from the face. A watch-key should never be used, because its hollow tube was so difficult to disinfect. Second, the comedones should be expressed, softening the face with hot towels or the steam atomizer for ten minutes, and expressing the comedones with the finger covered with sterilized gauze. Third, pustules and indurated nodules were dealt with according to the case. If suppuration had advanced so far that only a thin film of necrotic skin covered the pus, they should be opened; otherwise not. If it should be decided not to open them, then a forty-per-cent. salicylic plaster could be applied, or a drop of carbolic acid. This frequently would abort them. Laying the pustules wide open and scraping out the contents were never done. Fourth, as to medicinal agents, mercury, sulphur, and resorcin easily led the list in the choice. If the case was a very bad one, the patient should remain in the house and wear a mask formed of mercurial plaster; this should be worn constantly for three days, when the skin should be cleansed with benzene and all comedones and pustules emptied. This plaster treatment should be kept up until no new pustules formed, when Lassar's paste should be applied for a few days. Sulphur was preferable for office work, but it should be used in far greater strength than usual. It was of special value with oily skins, when the following lotion should be ordered to be applied:

℞ Sulphur lac	30
Alcohol	30
Water	37
Gum arabic	3
	100

On drying, this formed a thick powder and rapidly produced a scaling of the skin in most instances. If seborrhœa oleosa was present, resorcin was of special value, but it should be used strong enough to get its caustic effects and so reduce the thickened outside layer of the skin; thus:

℞ Zinc oxide	10
Resorcin	40
Benzoated lard	50
	100

This should be applied for fifteen minutes and then wiped dry. The application should be stopped as soon as desquamation appeared, and soothing pastes should be applied. In any case the scaling had to be done repeatedly. He had never seen a single case end in recovery under the use of sulphur ointments.

Dr. Samuel Sherwell, of Brooklyn, said that acne did not occur in children, but in young adolescents or young adults. He did not believe the speaker had laid sufficient stress upon the cases of constitutional origin, *i.e.*, the so-called diathetic or constitutional causes. Acne stood in great and close relation to the general economy. It was essentially connected with developmental causes and developmental troubles of the pelvic organs; also with dyspepsia of the lower bowel. Some people were constitutionally prone to acne—those with the hard, butcher type of skin, who had thickening of the mucous membranes, which did not appear silky as occurred in more healthy persons. He thought there was certainly some direct causal relations between pelvic troubles and acne, as well as between uterine functions and acne. He had seen at the periodic disturbances aggravation of the skin trouble; he had seen women either cured or greatly relieved of acne by the employment of catharsis and an oxytocic such as ergot, which acted upon the unstriped muscular fibre. In persons at the menopause he insisted upon catharsis and fewer but regular meals, thorough mastication of the food, and the relief of the pelvic viscera, for he believed that pelvic stasis was the determining etiological factor of acne. It may be due to sluggishness of the nervous system. Treatment of the reflexes from below the waist he considered to be the best for acne. Startin's tonic was advocated; this consisted of sulphate of magnesia, sulphate of iron, dilute sulphuric acid, syrup, and water. Although Startin was not a scientific man, he was accustomed to cure his patients in cases of acne by purging with sulphate of magnesia, by giving anti-rheumatic treatment and wine of colchicum, and, in cases of women, by tonic doses of ergot.

Dr. E. B. Cragin said that acne should be more prevalent at puberty when the glandular organs developed: it seemed perfectly natural that the sebaceous glands should be stimulated as well as the other glands at puberty. He had often thought that if the male sex were as particular about their complexions as the female, and went to the doctor, acne would be found in them as frequently as in women. After the age of puberty it was seldom that we saw cases of acne, except at the menstrual period. He had seen exacerbations of acne during menstruation.

Dr. Beverley Robinson had seen a great number of young men and young women at the time acne showed itself, and he begged leave to differ from some of the opinions of those present. The general conditions were all important, more so than local ones. It was rare to find young women with acne without some functional disturbances of their pelvic organs, with abundant, slight, or no menstrual flow. Sometimes the bowels were regular, and acne showed itself when there was some great strain upon the nervous system or bodily strength. He found acne more or less connected with the condition of anæmia, more or less pronounced. Personally he did not believe in allowing these patients to be in the hands of the specialist too much; we should keep control of these patients, although many specialists in cutaneous medicine managed these cases with great skill. The general health should be built up, and if the patients did not then improve, they should be sent to the specialist. He was skeptical regarding the treatment instituted in curing these patients unless they were kept in the best bodily shape. In view of the past he would insist upon the all-important influence of the general condition.

Dr. Frank C. Raynor, of Brooklyn, believed that the treatment of acne bore out the fact that we could not disassociate one organ from another. In the clinic with Dr. Sherwell the administration of a tonic combined with a laxative was employed, methods directed toward restoring the patient's general health.

Dr. L. Grant Baldwin, of Brooklyn, referred to one condition being present more than any other in cases of acne; that was, posterior deflection of the uterus. One case, treated by the dermatological department for a considerable time, without any effect, was brought to the gynæcological department and a complete retroversion was found; as soon as it was corrected and held in place the acne was practically cured in a week's time. There certainly was a close relation between the pelvic-organ disturbances and acne.

Dr. Sands closed the discussion by stating that he had never seen a case of acne in children, but he had seen it before the menstrual period set in, in one case three years prior to that event. The causal relations between acne and pelvic disturbances should be proven. If the replacing of a pelvic organ cured an acne, the placing of it again in its bad position should bring on acne again. The statement made by him in his paper, that only eight per cent. of all skin cases were acne, he thought to be too small; this was taken from the report of the American Dermatological Association, from their collection of eighteen thousand cases of skin diseases.

Officers Elected.—*President*, Dr. Robert F. Weir; *Vice-President*, Dr. William McCollom; *Recording Secretary*, Dr. P. Brynberg Porter; *Corresponding and Statistical Secretary*, Dr. Frank C. Raynor, of Brooklyn; *Treasurer*, Dr. Augustus D. Ruggles; *Members of the Executive Committee*, Dr. John H. Hinton (for four years), Reynold W. Wilcox (for two years); *Chairman for Borough of Manhattan*, Dr. J. Blake White; *Chairman for Borough of the Bronx*, Dr. S. Carrington Minor; *Chairman for Borough of Brooklyn*, Dr. Charles P. Gildersleeve; *Chairman for Borough of Queens*, Dr. Joseph F. Bloodgood; *Chairman for Borough of Richmond*, Dr. William C. Walser.

Erythrol Tetranitrate is especially useful as a prophylactic in preventing the onset of anginal pains. —C. R. Marshall.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, January 8, 1900.

CHARLES N. DOWD, M.D., CHAIRMAN.

Aneurism of the Innominate.—DR. A. L. FISK presented a case of this kind as a contribution to the special subject for the evening, *i.e.*, aortic aneurisms.

Recurrent Spindle-Cell Sarcoma with Glandular Involvement, Treated Successfully with the Mixed Toxins.—DR. WILLIAM B. COLEY presented this case. The patient was a man forty years of age, a carpenter by occupation. In September, 1896, he had first noticed a swelling in the parotid gland. This had gradually increased in size, until it was as large as an English walnut. It had then been removed by operation in March, 1897. It had quickly recurred, and had grown more rapidly, so that in May, 1897, a second operation had been performed by Dr. J. W. Wright at the Bridgeport Hospital. It had been found impossible to remove the whole tumor. The latter had continued to grow, and by July, 1897, had involved the submaxillary gland. Having at this time been regarded as a totally inoperable case, the use of the mixed toxins of erysipelas and bacillus prodigiosus had been begun by Dr. Wright. Very little improvement having been noticed after three weeks of this treatment, the patient had been referred to Dr. Coley for advice and treatment. Inasmuch as only moderate doses had been given, and in view of the fact that the patient's general condition was sufficiently good to warrant giving very large doses, it had been decided to give this treatment a further trial. The man had accordingly been admitted to the New York Post-Graduate Hospital on August 18, 1897. Physical examination at that time had shown a tumor occupying the entire left parotid region, and extending from the left auditory meatus forward nearly to the angle of the mouth, and from the angle of the jaw nearly to the orbit. The tumor was circular in shape, and measured three and one-half by four inches in diameter. It was markedly protuberant and ulcerated in the central portion over an area the size of a silver half-dollar. Just beneath the angle of the jaw was a secondary tumor the size of a hickory nut. The tumor had every appearance clinically of malignancy, and was hopelessly inoperable. The microscopical examination, made at the Bridgeport Hospital, had shown the growth to be a spindle-celled sarcoma. Daily injections of the mixed toxins had been made directly into the tumor, and the dose had been rapidly increased up to the point of giving a severe chill and a temperature reaction of 104° or 105° F. After about a week slight improvement had been noticed, as evidenced by diminished vascularity and decrease in size. This improvement had steadily continued, and the treatment had been kept up about ten weeks. At the end of this time the neoplasm had apparently disappeared, leaving a bright granulating area in the region of the ulceration. This had rapidly cicatrized, and a few weeks later the patient had been presented to the New York Surgical Society entirely free from any trace of the tumor. He had remained in good health up to the present time, nearly two years and a half since the beginning of the treatment.

Successful Double Resection of Cæcum and Small Intestine.—DR. COLEY also presented a patient upon whom he had successfully performed a double resection of the cæcum and small intestine for carcinoma seven and one-half months before. The patient was a physician, forty-three years of age, who had enjoyed good health up to the spring of 1898, when he had had symptoms referable to the right iliac region, and apparently characteristic of recurrent appendicitis. There were pain, slight fever, temperature reaching 102° F., marked local tenderness, and constipation. These attacks had confined him to bed for a period of about a week, after which his condition had slowly returned to the normal, the pain and tenderness entirely disappearing without leaving any trace of tumor behind. In October, 1898, he had had a second similar attack. After this, although the tumor had decreased very markedly, it had not entirely disappeared. There had been no loss of weight. In April, 1899, the induration had increased somewhat in size, and had become more tender. As there had been every reason to believe that he was suffering from chronic appendicitis, an operation to relieve this condition had been performed by Mr. Irving W. Cameron, of the Toronto General Hospital. The abdomen having been opened there had been found a hard mass, involving the cæcum and adherent portion of the small intestine, and making removal impossible without a double resection, for which both the patient and the surgeon had been obviously unprepared. The patient had come to Dr. Coley for examination on May 18, 1899, and, after a careful consideration of his general condition, aided by the accurate description of the condition found by Mr. Cameron, a radical operation had been advised. This operation had been done on May 26th, with the assistance of Dr. William T. Bull. The cæcum and about seven inches of the small intestine had been resected. The divided ends of the small intestine had been united by means of a Murphy button, reinforced by suture. The divided end of the ascending colon had been inverted and closed by means of a continuous suture. The same procedure had been adopted with the corresponding end of the small intestine beyond the ileo-cæcal valve. A lateral anastomosis had then been made by means of a large oblong Murphy button, and had been reinforced by interrupted silk sutures. Gauze drainage had been introduced and left for four days. The patient had suffered scarcely at all from shock, and had made an uninterrupted recovery. Both buttons had been passed on the ninth day, and the patient had returned to his home in Canada on the 21st day. He had remained perfectly well since, and had recovered his normal weight. At the present time, seven and one-half months after operation, careful palpation failed to reveal any evidence of return.

DR. J. A. WYETH, referring to the first case, asked what had been the object of introducing the toxins directly into the substance of the tumor, and was it Dr. Coley's custom to do this?

DR. COLEY replied that this was his practice whenever it was feasible, his experience having been that the results were far more satisfactory and more rapidly obtained when this could be done. He had, however, had good results in several cases in which it had been necessary to make the injection at some distance from the growth.

DR. WYETH asked if the temperature and inflammation had been exaggerated by this direct injection method.

DR. COLEY said that he thought this was apt to be the case, especially if sloughing were present, but such a pyogenic infection could be largely avoided by careful cleansing and disinfection before making the injections.

Sarcoma Cured by Acute Inflammation.—DR. WYETH said that he had asked these questions because his own experience had led him to believe that much of the beneficial results following the injections of the toxins was due to an acute inflammatory process not directly connected with any special virtue of these toxins. This statement was not intended as any criticism on the use of these toxins, because he believed they were directly beneficial. Fifteen years ago he had had a sarcoma of the abdominal wall examined by Dr. W. H. Welch, and proved by him and others to be a spindle-cell sarcoma. After every extensive operation Dr. Wyeth had resorted to injections of arsenious acid. The method had been so painful that after about ten days the patient had begged to have it given up. The speaker said he had been impressed with the marked reaction excited by the injections. The man had returned to his home, and much to Dr. Wyeth's surprise had completely recovered, and was to-day alive and well. This was a clear case of cure of sarcoma by an acute inflammatory process set up by injections of arsenious acid. In another case, one of very large sarcoma of the abdominal wall, he had exposed the tumor to the atmosphere, packing gauze around it, for the purpose of securing infection. This exposure had led to extensive suppuration, and the man had recovered, and had since been entirely well. The tumor had not been examined microscopically, but it had been a very large neoplasm, and to all appearances was a sarcoma.

Dr. Coley said that he had a case now under observation showing that cure was ordinarily not the result of a pyogenic process. The case was one in which the clinical diagnosis of all who had seen it was sarcoma of the fascia. Fluctuation having been noted, an aspiration had been made, and a large quantity of sterile, broken-down material removed. This proved that the destruction of the tissue had gone on as a result of the toxic agent, pure and simple, and not because of any infectious process.

Coley's Method Commended.—Dr. Wyeth said that he considered it essential to secure infection with the erysipelas coccus. He knew that Dr. Coley's treatment had not been very popular with the profession, but personally he was sure that it was both scientific and successful.

The Treatment of Aortic Aneurisms.—Dr. J. M. T. Finney, of Baltimore, read a paper on this subject. It was recognized, he said, that there were three essential conditions for treatment: (1) the aneurism must spring from the front of the vessel; (2) the sac must be perfect; (3) there must be a coagulating property in the blood. Macewen's method of needling the inner lining of the sac offered good chances of a cure, but the process was tedious, and months were required before the necessary coagulation would take place. In abdominal aneurisms only those sacs lying closely in contact with the abdominal parietes could be so treated, and obviously the diagnosis of this condition was impossible.

Gelatin Injections.—Since October, 1898, the French gelatin-injection treatment had been employed at the Johns Hopkins Hospital. In all nine cases of aortic aneurism had been treated by this method. In all these cases the blood-coagulation time had been carefully noted. Not a single patient had been cured, though in one case the size of the aneurism had been decidedly diminished. It seemed quite certain that the injection of the gelatin did not markedly affect the coagulability of the blood. These injections had been painful and sometimes had been followed by chill and an elevation of the body temperature to 103° F. There was, however, apparent merit in the treatment sufficient to warrant giving it a further trial. From a very recent experience he was now inclined to advise a combination of the gelatin injections with the wiring method.

The Wiring Method.—Charles H. Moore, of the Middlesex Hospital, had first undertaken the cure of a thoracic aneurism by the introduction of a foreign body into the aneurism. Although this first attempt had resulted in failure because of faulty technique and consequent sepsis, the originator of this method had felt impressed with the soundness of the theory upon which the treatment was founded. Dr. D. D. Stewart, of Philadelphia, deserved the most credit among American surgeons for the development of the proper technique. The needle should be large enough for easy passage of the wire. A drop of sterile oil would materially facilitate the passage of the wire. The escape of blood was very slight. The needle should be covered from the shoulder to within 1 cm. of the point with some insulating material, so that the electric current would not be dissipated at the point of entrance of the needle into the sac wall. The speaker recommended insulating the needle with the best black French lacquer. The needles so insulated could not be boiled, but they could be sterilized by exposure for one hour in a chamber in which the air was heated to 160° F. The disposition of the wire in the sac was an important factor. A small quantity of fine wire, having a fine springy quality, should be selected. The corrosion of the wire by the electric current made a rough surface, which facilitated the deposit of fibrin; hence, within proper limits, the wire giving the roughest surface was the best. The treatment could be carried out experimentally by using flasks of different capacities. Experiment of this kind had shown that ten feet of fine and highly springy wire would fill a 500 cc. flask. They had found at the Johns Hopkins Hospital that the best wire was one made of seventy-five parts of copper to one thousand of silver, drawn down from No. 8 to No. 27. Such a wire gave a closer coil than steel wire. Experiments had been made also regarding the comparative value of steel and silver as electrical conductors for this work. The experiments had been made at an abattoir in a jar of freshly drawn hog's blood. After a current of 100 milliamperes had been passed for an hour both wires had been examined, and it had been found that the silver wire had been more disintegrated. Experiments made on dogs had shown that a current of 20 milliamperes was effective and better than one of 100 milliamperes. Such treatment was particularly suitable for cases of thoracic aneurism because it could be done under cocaine anæsthesia. If after passing in a small portion of the wire a kink should occur, more wire should be inserted through another needle, and then both portions of wire connected with the same pole of the battery.

Dangers.—Of course, sepsis was an omnipresent danger. One of the greatest dangers, particularly in multilocular aneurisms, was rupture of a secondary sac, due to the rapid filling of the main sac with coagulum and the shunting of the blood against a portion that had hitherto not received such a strain. General arteriosclerosis would, in general, weigh against this operation. While clinical experience had shown that wire without galvanism would collect fibrin in the lesser sac, it probably would not do so when exposed to the full force of the aortic current. The size of the sac opening could not be diagnosed from the character of the bruit. Another danger was that of emboli breaking from the sac wall during the introduction of the wire. There was a possible danger of puncture of the sac wall by the wire, especially if the wire was made of steel, but this danger was rather theoretical than real.

Results.—In all of the cases upon which autopsies had been held, the effect of the wire in whipping out fibrin from the blood had been marked. Thirty-five per cent. of the reported cases attested the value of the operation by the palpable improvement and the prolongation of life. In one of the cases that had come under his own observation the wiring had been done three times, and after each operation there had been comparative comfort for a number of months. Of the two thoracic aneurisms reported in the paper, one had been wired last August, and was now considered by

Dr. Osler to be cured. Of nine other cases, death had been apparently hastened in six; however, none of these patients could have lived long. Clinical and post-mortem evidence certainly pointed to the efficacy of the method; its great drawback was the lack of accuracy in diagnosis. His first case had been one of abdominal aneurism occurring in a man who had been admitted to Dr. Osler's service on July 19, 1898. Wiring had been done on August 18th. Considerable difficulty had been experienced in exposing the sac. Only five feet of the silver alloy wire had been used, and a current of from 30 to 70 milliamperes had been kept up for one hour. The sac had been made immediately smaller and firmer. The patient had experienced more pain, however, immediately after the operation. He had died on the twentieth day, and the autopsy had revealed no actual rupture, but there had been a very rapid oozing of blood. His second case had been admitted on April 24, 1899. Seventeen injections of one-per-cent. gelatin had been previously given on the medical side of the hospital without any appreciable benefit save some relief to the pain. On August 11th wiring had been done, ten feet of the silver alloy having been used with a current varying from 10 to 20 milliamperes. Following this there had been an improvement in the symptoms for about one week, and then there had been a sudden increase in the size of the chest, but the patient would not consent to another wiring. Fifteen more injections of gelatin had been given. This was the case in which Dr. Osler now thought a cure had been effected, although so far it had been classed only as a case showing improvement from the treatment.

Conservatism Advised.—Dr. J. A. Wyeth said that these desperate cases certainly justified desperate measures. The treatment so well outlined in the paper was certainly desperate, yet the results fully justified the means. Many years ago he had had occasion to look up every case reported in which operation had been done. As a result of this study he had been led to feel that distal deligation was not contraindicated in cases of aneurism of the ascending and transverse segments of the aortic arch, complicated or not complicated by orifices of the large vessels. The results obtained in this way were probably as good as any others that could be shown. Dr. Wyeth then cited an interesting case—that of a man of twenty-six years, a syphilitic, with an aneurism almost at the point of rupture when first seen. Under aseptic precautions he had inserted twenty-four hare-lip pins into the aneurism, just like the pins in a pin-cushion. Eighteen hours later he had removed the pins. There had evidently been coagulation of the blood on the walls of the aneurism, because the pulsation was distinctly less. The operation had been repeated four days afterward, and the pins had been left in for twelve hours. The patient had been put upon increasing doses of iodide of potassium, and he had rapidly improved. He had left in two months with evident solidification of the aneurism. He had returned to his work as a carriage painter, and two years afterward had fallen dead, apparently as a result of a cerebral embolism. In one of the cases upon which he had operated he had been surprised to find that the aneurism had already solidified. Personally he would prefer to give the rest and iodide treatment a very thorough trial before subjecting the patient to deligation or to wiring. He was of the opinion that if the profession at large understood better the proper treatment of syphilis there would be fewer cases of aneurism to be treated.

Dr. P. Bolton spoke of the experience at the Hudson Street Hospital with the gelatin injections. Four cases had been treated at that hospital with these injections during the past year. The method had been found to have many disadvantages, and none of the cases had resulted in a cure. The injections were followed in every instance by severe pain, and sometimes by chill and fever.

Dr. Finney said that he agreed with Dr. Wyeth regarding the advisability of attempting the rest and iodine treatment before resorting to the other methods. It had been tried in one of his cases without avail; another patient had been so unruly that it could not be continued, and in a third it could not be employed because the patient had been unable to lie down.

Therapeutic Hints.

Endermic Application of Salicylic Acid.—Sigalas and Combemalle have called attention to the fact that salicylic acid is absorbed through the epidermis. In an oily vehicle, when rubbed on the skin the acid may be detected in the urine after five minutes. If, after rubbing, the area is covered with oiled silk and enveloped in flannel, the effect is enhanced. Oil of wintergreen may be employed. A favorite formula is:

℞ Acidi salicylici	10
Alcohol	50
Ol. ricini	100

—*Merck's Archives.*

Hæmatemesis.—Rest in bed, absolute immobility, a hypodermatic injection of ergotin over the epigastrium, and ice locally over the same region. Internally one or two grains of opium, and every two hours a teaspoonful of the following mixture:

℞ Ergotin	ʒ i.
Acidi gallici	gr. x.
Extr. opii	gr. ij.
Syr. terebinthinæ	℥ i.
Aquæ	℥ iv.

In case of syncope employ horizontal decubitus, injections of ether, flagellations, mustard leaves to the legs, etc. Upon the development of signs of peritonitis indicating perforation of the stomach give morphine hypodermatically.

Scarlet Fever.—All children ill with scarlet fever should be kept in bed during the rash, no matter how mild it may be; and furthermore, such children should be confined to warm rooms, or, better still, to bed, for four or five weeks from the appearance of the initial symptoms. At least twice a week during this time the urine should be examined, and upon the appearance of the slightest unfavorable symptom the child should be sent back to bed again if he has already been allowed to be about the room. If scanty, albuminous urine and dropsical effusion appear the physician must direct the most energetic efforts toward making the skin or intestines temporarily assume, as far as possible, the functions of the kidneys, throwing on the latter, at the same time, as little work as possible in the way of excretion of nitrogenous refuse. The copious use of water, if tolerated by the stomach, will act as one of the very best of diuretics. Should the urine still remain scanty, then diaphoresis must be induced in order to increase the action of the skin —first, by means of baths, and then, if necessary, by drugs. The warm bath (98°–100° F.) every fifteen to twenty minutes is often grateful to the child, and if supplemented by a flannel pack is very efficacious. Any of these methods will be assisted by the internal use of diaphoretics, chief of which are the preparations of jaborandi. Sips of the hot infusion of the leaves (ʒ i. to Oi.) act both as a powerful diaphoretic and sialagogue. To avoid the latter action Smith prefers the alkaloid pilocarpine, gr. $\frac{1}{40}$ to $\frac{1}{20}$, conjoined with an alcoholic stimulant, every four to six hours.

Should this fail, the same writer speaks highly of the following:

℞ Potassii acetatis,
Potassii bicarbonatis,
Potassii citratis........................āā ʒ ij.
Inf. tritici repentis .... ℥ viij.
M. S. A teaspoonful every three or four hours to a child of five years.

Most palatable and efficacious is the following:

℞ Liq. ammonii acetatis,
Syr. acidi citrici..........................āā ℥ ij.
M. S. Teaspoonful every hour in hot lemonade.

—Marcus P. Hatfield: "American Text-book of the Diseases of Children."

Cystitis.—

℞ Extr. hyoscyami,
Extr. cannab. indic........................āā 0.4
Sacch. alb 5.0
M. ft. pulv. No. xii. Sig. One powder t.i.d.

—Ultzmann.

Chronic Laryngitis.—

℞ Alum. crud.,
Sacch. alb...............................āā 5.0
Morphinæ hydrochl........................ 0.5
M. S. Use as insufflation.

—Von Schrötter.

Malaria.—Dr. Nelson W. Wilson, in the *Buffalo Medical Journal* for November, in an article on "Pen Pictures of Malaria," says that the severe chills were broken up by the administration of what the soldiers called "knock-out drops." This was made up as follows:

℞ Spir. chloroformi,
Tinct. opii..............................āā 1.33
Spir. frumenti 60.0
M.

As an Adjuvant in Epilepsy.—

℞ Zinci oxidi.......................... 0.10 cgm.
Pulv. valerian........................ 0.10 "
Pulv. bellad .... 0.01 "
Saponis med.......................... q.s.
For one pill. Give four daily.

—Jules Voisin.

To Apply Locally in Pertussis.—

℞ Acidi phenici cryst 1.50
Glycerini puri.............................. 10.00
Syr. tolutan 5.00
M.

Apply to the throat in children below one year of age. After the age of three years substitute a two-per-cent. solution of cocaine for the tolu, and for extensive applications decrease the strength of carbolic acid.—Guida.

Internally:

℞ Coccionell. subt. pulv.................... 0.05–0.2
Ammon. carb........................ 1.00–2.0
Syrup aurantii.......................... 20.0
Aquæ destil.................... q.s ad 100.0
M. S. Shake and give a teaspoonful every two hours.

—Naegeli-Akerblom.

Odontalgia.—

℞ Orthoformis,
Ac. carbol..............................āā 10.0
Camphoræ,
Chloral hydrat..........................āā 4.0
M. S. Apply with absorbent cotton to the previously dried tooth cavity.

—Danchez.

Burns.—Apply ichthyol, dust with talc, and bandage. In more severe forms ichthyol vasogen should be applied on compresses.—Mueller.

Urotropin decomposed by acid urine into ammonia and formaldehyde destroys bacteria in the urine in one or two days.—Blech.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

PRINCE OF WALES' HOSPITAL FUND—SUNDAY FUND—SURGICAL TREATMENT OF CIRRHOTIC ASCITES—PERFORATING GASTRIC ULCER—CONCLUSION OF THE DEBATE ON TABES AND GENERAL PARALYSIS OF THE INSANE—DEATHS OF SIR R. THORNE THORNE AND CAPTAIN HUGHES.

London, December 22, 1899.

Yesterday the Prince of Wales presided over a meeting to consider the distribution of his hospital fund for the year. The total receipts for the year have been £47,806, or about £9,000 more than last year. The expenditure has also diminished by more than £1,500. This is certainly an encouraging statement for a treasurer to have to make. It had been intended to make a special effort to secure £50,000 for distribution, but considering the appeals made to the public through the outbreak of war this project was wisely abandoned. The committee was able to distribute £42,000 among hospitals and convalescent institutions. Last year only £32,500 was the amount. The amount allotted will cause two hundred and eighty-seven closed beds to be reopened—but there are still four hundred beds unoccupied for want of funds.

The Sunday fund meeting was held last week, when it appeared the total sum collected was £53,504, 11*s.* 1*d.* The grand total for the twenty-seven years in which the fund has been at work has now passed the million sterling, on which the council congratulated Sir S. Waterlow, who has all along taken a leading part in the management, and who is understood to have desired to see this sum collected. I regret that I cannot congratulate him on some points in his management. He is too prejudiced, and allows his prejudices to carry away his judgment. Then he suffers the secretary to imitate him and exceed him, as most subordinates are apt to do.

It is satisfactory to find that the Prince of Wales fund has not caused any injury to either the Sunday or Saturday organizations. By tapping a different stratum it has brought fresh sums to the hospitals, and would seem to have stimulated charity generally, so that an increase has taken place all around. The Lord Mayor remarked that the meeting lasted little more than half an hour, and considered that that showed the business-like methods of the fund. I cannot indorse his view; it seems rather to indicate that the meeting merely accepted the statement of the officials and left Sir S. Waterlow and the secretary to carry on their policy by boycotting some institutions and irritating the managers by injurious favoritism.

Dr. Rolleston and Mr. Turner related at the last meeting of the Medical Society two cases of surgical operation for the production of peritoneal adhesions in cirrhotic ascites according to the plan introduced by Dr. Drummond and Mr. Morison. They have thus added two to the ten cases recorded, and that others have been operated on but not recorded is more than probable, for they remarked they knew of one such unsuccessful case. As to their own cases, one patient improved—lost his ascites, but has an enlarged spleen; in the other the fluid accumulated again and again, and they claim at the most only a slight amelioration. In both the cases brought forward the liver and omentum were stitched to the cut abdominal parietes, and this was urged as necessary to secure good adhesion. Early operation was recommended. On referring to the records of previous cases (Medical Record, February 4, 1899), it would appear that four out of the ten patients recovered, while three of the remainder died from the operation. If the other three improved, the figures are not specially encouraging, and with the one death mentioned and the two new cases somewhat better, the proceeding is evidently a grave one. But as to its value I may mention some of the remarks made by the speakers present. Dr. P. Weber referred to a case in which the patient recovered after tapping, and said that when the specific gravity was over 1.020 there was probably inflammation, and one or two tappings might result in cure.

Dr. F. J. Smith objected to the old method of tapping, and thought a scientific laparotomy might be better. He thought that when ascites appeared in cirrhosis, the end was near, and so a simple operation was preferable. Dr. Middleton had published a case of hemorrhagic ascites which resulted in recovery after tapping. If done with a fine trocar, it was not a serious affair. Mr. Wallis mentioned another case of recovery after four tappings. Dr. Ewart mentioned a patient who had undergone fifty tappings. Mr. Turner tapped as before, proceeding with his incision, as it saved time and he had never seen any ill effect. Dr. Roberts (president) could not agree that ascites rendered the prognosis as bad as had been stated. He had seen many cases of undoubted cirrhosis end in recovery after simple tapping. Dr. Rolleston admitted that some patients did so recover, but not as a rule. He attributed the hemorrhage into the fluid to previous tappings.

Perforating gastric ulcer was discussed at the last meeting of the Clinical Society. Mr. A. Barker gave a review of twelve consecutive cases on which he had operated of late years, all treated on similar conditions. Five patients out of the twelve recovered. In two of the fatal cases the patients survived fifteen and fourteen days respectively, one dying of subphrenic abscess, causing pleuro-pneumonia, the other from bleeding of the ulcer into the stomach. In all twelve cases mopping out the abdomen was done instead of flushing, which he used in former cases but gradually discarded. Of the five successful cases, all the patients were well for considerable periods, some for years, after the operation.

On the question of flushing or mopping, considerable divergence of opinion was expressed by the surgeons present—some agreeing with Mr. Barker, others holding flushing to be better, and others again thinking that mopping was equal to some cases but flushing was required in some. One held that flushing should be carried out thoroughly, the intestines being allowed to float out of the body. All agreed that the earlier the operation the more hopeful was the case. Mr. Bidwell had collected fifty-five cases, in thirty-three of which the time before operation was mentioned, and found that one-third of the recoveries had been operated on within six hours and five others within twelve hours. All within twelve hours were successful, and half of those between twelve and twenty-four hours.

With regard to symptoms it seemed generally agreed that liver dulness, so often spoken about, gave no indication. It was admitted, too, that pain is very uncertain, Mr. Bowlby saying cases are overlooked because almost every one expected pain. When present, pain is not located as might be expected—it was said by one surgeon it "might be almost anywhere or indeed absent." Another had found it all in the pubes or in the lumbar region. In a number of cases it seems limited to the lower part of the abdomen. This question of pain is one of great importance when the patient is first seen.

The pathological debate was concluded on Tuesday. Dr. Beevor thought it was exceptional for tabes to end as general paralysis. He dwelt on the slowness of tabes compared with general paralysis. In thirty-nine cases of tabes he traced syphilis in eleven, chancre without secondaries in seven, gonorrhœa without chancre in ten, doubtful gonorrhœa without sore in five, and no history of venereal in six. Until changes in the cortex were found, in the majority of cases he would hardly like to pronounce the two diseases identical.

Dr. Henry Head said he had been at work on the course of the sensory fibres in tabes, and gave some account of his research, which has yet to be published. He came to the conclusion that the two diseases are due to an identical process affecting different portions of the nervous system.

Dr. P. Stewart said there must be an additional factor besides syphilis, and this he thought was overstrain, bodily in tabes and mentally in general paralsis. He referred to Edinger and Heber's experiments on rats as agreeing with this view, which was supported by many clinical facts.

Dr. Robert Jones admitted syphilis to be the most important factor, but could not go so far as to assert there would be neither of these two diseases without it. Out of five hundred and twenty autopsies on general paralytics, the proportion of tabetic cases did not exceed two per cent. In twenty thousand cases of syphilis collected by Lewin, one per cent. of the patients became insane but not one a general paralytic. He thought that syphilis injured the constitution and prepared the ground for other factors—overstrain, alcohol, and excitement or excesses—singly or combined.

Dr. B. Abrahams said that to apply the meta- or parasyphilitic doctrine to every case, as Hirschl did, was going too far. No doubt it was the most important factor in the production of degeneration of neurons, but not the only one. Strain was to be reckoned with, and arterial degeneration played no slight part in determining the localization of syphilitic sequelæ. Dr. Mott had proved that both diseases were primarily neuronic degenerations—not interstitial outgrowths. Probably the neurons were affected at the time of the syphilis, but not in a way that we could detect by the microscope, though the injury resulted in lessened vitality and death years after the prime cause.

Dr. Beach had found thirty-six cases of juvenile general paralysis in literature, and could add two which he had met with. He found evidence of syphilis in twenty out of twenty-five cases in which the history was given. He held that it was commonly, though perhaps not always, due to congenital syphilis.

Dr. Mott replied to various points mentioned in the very notable debate elicited by his paper. He was naturally satisfied to find the preponderating views agreed with those he had put forward. He admitted the influence of strain, both mental and physical, but syphilis was the primary injury and produced loss of durability of certain neurons. The two diseases were thus due to the same morbid process, but he did not say they were clinically identical. The prevention and treatment, however, would be the same.

Sanitary science has lost an enlightened leader in Sir Richard Thorne Thorne, M.D., K.C.B., F.R.S., principal medical officer to the Local Government Board, and as such the head of the sanitary department of the country, who died on Monday last, the 17th, aged fifty-seven years. He was a crown member of the General Medical Council, and took an active part in its recent session. On the last day, the 5th inst., he carried resolutions on preliminary education and on public health diplomas. His many masterly reports, his work at international conferences, his measures to meet the possible invasion of plague and cholera, and other scientific and sanitary labors are known everywhere. We who knew him as a man feel we have lost one pre-eminently qualified for the great position he held, and one with whom it was a privilege to meet and confer.

Captain Hughes, R.A.M.C., who was killed in the fight at the Tugela River, was also a notable sanitarian. He was one of the sanitary officers at Aldershot when Sir R. Buller selected him to be adviser on his staff. His death is a decided loss to the army medical service.

THE STATIC INDUCED CURRENT.

To the Editor of the Medical Record.

Sir: In his reply to my letter Dr. Morton diverts attention from the main points of contention: First, that he makes extravagant and utterly unjustifiable therapeutic claims; second, that he has persistently exploited his own originality at the expense of the originality of others. It is not a question whether Mauduyt and other authors now almost forgotten ever used the term "static induced," or whether in connection with it physiological tetanus was described previous to 1881, but whether Dr. Morton was the originator of the principle upon which the whole subject is based. Most assuredly he was not. It needs but a glance at these old illustrations to make it evident that the more recent ones of Dr. Morton are in their essential characteristics absolutely the same, and that from the arrangements represented by these illustrations the spark-gap could be so adjusted as to produce the so-called static induced current with the power to induce continuous muscular contractions.

THE NOMENCLATURE OF APPENDICITIS.

To the Editor of the Medical Record.

Sir: Will you allow me to add a few words to what Drs. Carstens and Edebohls have said, in your issue of December 30th, in regard to the nomenclature of "appendicitis." First of all, this term well illustrates that a private individual, especially one who knows little or nothing about etymology, has no more right to coin a word than to coin money. All new medical words should be submitted to some national body for approval or disapproval before passing current. Perhaps a committee of the A. M. A., perhaps a committee of medical editors, perhaps the American Academy of Medicine, could be agreed upon. Meantime editors should unite to keep out of print some of the more recent abuses of language.

It is a plain, common-sense rule that a Greek ending, such as itis, should be attached only to a Greek stem. In other words, a Greek translation of "processus vermiformis" must first be made. Of the various words suggested—epityphilitis, scolecoiditis, scolecitis, ecphyaditis, helminthitis, etc.—it seems to me that scolecitis is the most euphonious. Scolecoiditis —inflammation of the worm-like—is unnecessarily accurate. We do not say salpingoiditis, staphyloiditis, amygdaloiditis, etc., but simply name the organ after the object which it resembles. Epityphlitis is satisfactory enough, except that we often want to qualify with other prepositions, and peri-epityphlitis or para-epityphlitis is awkward.

A. L. Benedict, M.D.

Buffalo, N. Y., January 2, 1900.

To the Editor of the Medical Record.

Sir: In Dr. Carstens' letter to you, published in the Medical Record December 30, 1899, I read with great satisfaction that Dr. Henry Draper, in 1871, had apologized for using the hybrid term appendicitis. The time of which Dr. Carstens speaks as having brought forward the monstrosity in question was the time of the "per orem" man.

Napoleon, on December 26, 1805, without further preliminaries, pronounced and proclaimed through the *Moniteur*, "The dynasty of Naples has ceased to reign." Dr. Edebohls surpasses the great man in so far as he wipes out altogether a fact established in literature as if it had never existed. Perityphlitis is indeed a synonym for appendicitis, as shown in my paper, "On the Term Appendicitis," in the *New York Medical Journal*, May 20, 1899, and with this fact we have to reckon. Dr. Edebohls' history and bibliography of appendicitis are rather incomplete, since he leaves out publications in which the disease has been called by the name "perityphlitis." Two such papers, and most important ones they are, by Ludwig Herzog, Dr. Edebohls could have seen mentioned in my article just spoken of. Cardialgia is a synonym for gastralgia, although calling gastric pain cardialgia is as nonsensical as speaking of headache in the feet. Technique means technical; nevertheless it is a synonym for the good English (Webster's Dictionary) word technics. True, all this is to be regretted, but the fact remains.

A. Rose, M.D.

NEEDED REFORMS IN THE AMBULANCE SYSTEM.

To the Editor of the Medical Record.

Sir: An article from your pen in the issue of January 6, 1900, gives me quite a surprise. The article on "Needed Reforms in Our Ambulance System," while putting certain features of the ambulance service as it is conducted in a very proper light, supplies but a very poor remedy.

The very reprehensible habits of refusing to receive patients apparently about to die, and of transferring patients under similar conditions, are old ones. Now for the first time this matter can be brought under direct control, and a positive and prompt halt can be, and I doubt not will be, called. The comptroller can cause all hospitals to report to him under the present law, and hospitals can thus be made to report all cases received in a condition in which any one can see that the patient is about to die and from whence the dying patient comes. This will prove an effectual check at once. The comptroller has this matter under consideration, and this method of checking the abuse has been called to his attention. Only a few days ago a woman died from want of prompt attention. Nearly two hours elapsed before help arrived, and then it was too late, because all ambulances were busy—all this when there were fifteen doctors' offices within four hundred feet of the woman who was so much in need of immediate medical services, with no call upon these doctors.

Can we not see that to have ambulances take all cases without question is not right? Or, in the words of your editorial, "there should be no such thing as questioning the fact whether a given patient. . . . Every institution should take every case presenting itself."

There surely are many cases in which the people prefer to go to their homes when injured in the street, and are able to procure without public aid every attention they require, and surely when they are in their homes, as in the case mentioned in this newspaper report, with physicians all about, some of them would undoubtedly be willing to attend even if the person is unable to pay for services, and officers should be instructed not to call ambulances for such as wish carriages to go to their homes; and when persons require immediate attention frequently the neighborhood doctors can supply it for those who prefer it quicker than an ambulance could reach the sufferer; and police should call such physicians when the sufferer so desires. Nor should the ambulance surgeon, even when he has reached a case, and possibly dressed a slight wound, compel the person to go to the hospital, especially if the injured one is quite competent in every way to decide for himself and prefers to go home.

To return to the hospital without the injured person should not be considered anything against the ambulance surgeon, as it seems to be now.

As the matter now stands, it is a grab game, and only when there are an extra number of ambulance calls all at once is there any lack of opportunity for any one, rich or poor, to go to a hospital.

W. Washburn.

January 6, 1900.

LIGATION OF THE STUMP IN APPENDICITIS.

To the Editor of the Medical Record.

Sir: Apropos of the question of ligation of the stump in appendectomy, so illustratively discussed by Dr. John A. Wyeth in your last issue, I beg to call attention to the modus operandi advised in my publication, "Is Appendicitis a Surgical Disease?" in the *New York Medical Journal*, December 10, 1898, from which I quote the following:

"After squeezing the contents of the appendix into the cæcum, the fundus of the appendix is tied with a formalin catgut ligature. The same procedure is repeated about half a centimetre below. Then with one stroke of the scissors the appendix is severed closely above the lower ligature. By previously having squeezed out the contents of the appendix and by tying doubly afterward, the exit of any fecal matter is prevented. The protruding mucous membrane of the appendix, after being disinfected with a strong solution of bichloride of mercury, is then seized with an artery forceps and pulled out as far as possible. Now it is cleanly cut off with the scissors. There is then left a muscular-serous flap, which can easily be united by three Lembert sutures. After the removal of the mucous membrane some iodoform powder is dusted over the remainder of the mucous membrane in the depth; but dusting the little wound margins, which are to be united, is to be carefully avoided. All these manipulations take place after the neighboring intestines, particularly the area situated directly below the appendix, are protected extensively with sterile compresses."

If no perforation has taken place, it is evident that the only possible source of infection during appendectomy could come from the interior of the appendix; that is, mainly from its mucosa and submucosa. The removal of such area is certainly the safest way of eliminating its infectious property.

Carl Beck, M.D.

New York.

Immunity against Malignant Œdema.—Malignant œdema was one of the first diseases against which immunity was produced by infection toxins. The filtered cultures of the bacillus in sufficient doses produced death with the same symptoms as those caused by the living organisms, but a relatively large quantity is necessary. Chamberland and Roux (1887) found that if guinea-pigs were infected with several non-fatal doses of cultures, sterilized by heat, or freed from the bacilli by filtration, immunity against the living organism could be developed in a comparatively short time. They found that the filtered serum of animals dead of the disease is more highly toxic and also gives immunity when injected in small doses. These experiments have been confirmed by Sanfelice, Muir, and Ritchie.—*Manual of Bacteriology.*

Medical Items.

An Alpine Ambulance Association.—Among the increasing number of Alpine accidents many are of a kind which no prudence could prevent nor medical aid benefit. Many cases, however, occur in which some knowledge of the principles of "first aid" might diminish the severity of the results or even save lives. A movement has recently been inaugurated, somewhat analogous to that of St. John's Ambulance Association, for the practical instruction of Alpine guides in the treatment of wounds, fractures, frost bites, etc. Dr. O. Bernhard of the Engadine has published in a book form a course of lectures on mountain accidents, which has recently been translated into Italian and which has gained for its author the decoration of the cross of a Knight of the Crown of Italy.—*Medical Magazine.*

Practical Patriotism.—At a meeting of the West London Medico-Chirurgical Society on December 1st, it was unanimously resolved to organize a scheme for affording gratuitous medical attendance in their own homes to distressed wives and families of soldiers serving with the colors. A committee was appointed to carry out a scheme similar to that which the Chelsea Clinical Society had organized in certain districts in connection with the Soldiers and Sailors' Families Association. As the West London Medico-Chirurgical Society has over five hundred members, its action in this matter will assure free medical attendance to distressed families of soldiers through a very wide district.—*The Lancet.*

Sarcoma of the Stomach in a Child Three and One-Half Years Old.—Finlayson (*British Medical Journal*, December 2, 1899, p. 1535) reports the case of a boy, three and a half years old, who presented an aspect of feebleness, with great pallor or anæmia, and with slight indications of rickets, especially in the lower extremities. The pallor was extreme, and did not seem to be accounted for by anything in the previous history, which was one of failing health for three months following an attack of vomiting of short duration. This vomiting was not associated with the appearance of blood. It was followed by disturbed action of the bowels, at first constipation, but subsequently intercurrent diarrhœa. A vague account of some tarry stools was obtained, but no blood was observed during the three and a half months the child was under observation. On one occasion only some brownish fluid like altered blood was brought up from the stomach, and even this might have been due to the use of raw meat juice. There seemed to be no pain anywhere and no tenderness in the abdomen, which was slightly distended, as might be expected in a rachitic subject. No tumor could be felt, but after a time, on careful search, the spleen, as supposed, was felt high up under the left ribs, in the lax abdomen. Such enlargement as was thought to be present was attributed to rickets. The aspect of the child throughout was one of extreme apathy. He lay listlessly nearly all day, often curled up, with the head bent forward. During the periods of slight improvement that occurred several times, he would brighten up for a few hours, and amuse himself with toys, but this was of short duration. Even when dullest, however, he could speak and tell his name. An examination of the blood disclosed no excess of white blood-corpuscles. The number of erythrocytes was 3,200,000 per cubic millimetre, without poikilocytosis. In the course of five weeks the number had fallen to 2,560,000, and the hæmoglobin percentage was twenty. After the lapse of another month the number of red cells had declined further to 1,812,500 and the hæmoglobin to fifteen per cent. After an additional interval of three weeks the red cells numbered 1,593,000, and the white were estimated as 1 : 177 red. No alteration in the shape of the corpuscles was found. A few small glands were felt in the neck, and one or two in the axilla. With the gradual diminution in the number of red corpuscles there was progressive pallor, with a sallow tinge almost of a lemon color. There was slight but almost continuous pyrexia, the temperature ranging from 100° to 101.5° or 102° F., occasionally reaching 103° F. Toward the close the temperature continued at 104° F. for a few days, when some pulmonary disorder ended the case. Ophthalmoscopic examination disclosed only a little passive congestion of the veins of the fundi. On physical examination of the thoracic organs wheezing râles were heard at times in the latter part of the course of the case, and a systolic murmur at the apex. Toward the close of the case a little puffiness of the feet and hands, and even of the face, was noticed. During the time the child was under observation the weight declined from twenty-five to twenty-two pounds. The appetite was impaired, the child seeming to prefer milk to anything else, but he was so apathetic as to seem rather indifferent to food. Vomiting was a prominent symptom, at first being only occasional, but subsequently becoming more persistent. It could not be traced to have any special relationship to feeding or to any definite cause, and the vomited matter was not suggestive of anything special except on the single occasion referred to. Death resulted from exhaustion, with a terminal pyrexia associated with pulmonary congestion. Upon post-mortem examination a bulky tumor was found in the posterior wall of the stomach closely impinging on the greater curvature, and rather nearer the cardiac than the pyloric orifice. It projected almost equally externally and internally. On the mucous aspect it measured 2.5 by 2.5 cm., the submucous infiltration being about 3 cm. in length. On the serous aspect it measured 4 by 4.5 cm. and the projection was 1.8 cm. The tail of the pancreas was somewhat closely related to the tumor posteriorly, but dissection showed it to be distinctly separated by a thin veil of connective tissue. On the mucous aspect of the stomach, and immediately distal to the main rounded, projecting mass of the tumor, there was a small circular area with a depressed centre and obviously infiltrated edges. The central portion of this area was the only part conveying the impression of ulceration, and even there the appearances were not conclusive. Many of the glands in the mesentery were slightly enlarged, but on microscopical examination they exhibited no evidence of involvement in the new growth. On microscopical examination the tumor was found to be a highly cellular sarcoma, with both large and small spindle cells.

Disinfection of Railway Carriages in Germany.—Dr. Navarre (*Journal d'Hygiène*) contends that third-class compartments, which have been found in Germany to be four times as rich in bacteria as those of other classes, ought to possess smooth surfaces and rounded angles. The woodwork should be protected by varnish, which may be readily washed and disinfected. The floor should be covered with linoleum, which may also be readily cleansed and changed. The partitions and other woodwork should be carefully washed with water containing soda, to be followed by a 1 : 1,000 sublimate spray. For the second- and first-class carriages Dr. Navarre would do away with stuffed cushions, which become full of dust impossible to displace thoroughly. He would cover the seats with flexible leather and the floor with lineoleum. If movable cushions are retained they should be beaten mechanically at regular periods. Formaldehyde gas should be generated in these carriages, being not only an excellent deodorant, but a reliable disinfectant. The smell of the gas disappears rapidly after a short exposure of the interior of the carriage to the air.—*Public Health.*

Milk for Diabetes.—Dr. R. T. Williamson suggested the following method of preparing for diabetic patients an artificial milk practically free from milk sugar: "To about a pint of water placed in a large drinking-pot or tall vessel, about two or three tablespoonfuls of fresh cream are added and well mixed. The mixture is allowed to stand for twelve or twenty-four hours, when most of the fatty matter of the cream floats to the top; it can be skimmed off with a teaspoon easily, and on examination it will be found practically free from sugar. (The milk remains dissolved in the water.) This fatty matter thus separated is placed in a glass and mixed with water. Then the white of an egg is added and the mixture well stirred. The water and white of the egg are added in sufficient quantities to make a mixture which has the exact color and consistence of ordinary milk. If a little salt and a trace of saccharin be added a palatable drink is obtained, which has almost the same taste as milk and which contains a large amount of fatty material and is practically free from milk sugar. With very little practice the right proportions can be easily guessed, and of course much larger quantities than those mentioned can be prepared.—*Medical Chronicle.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended January 12, 1900:

LEPROSY IN HAWAII.

By E. S. GOODHUE, M.D.,

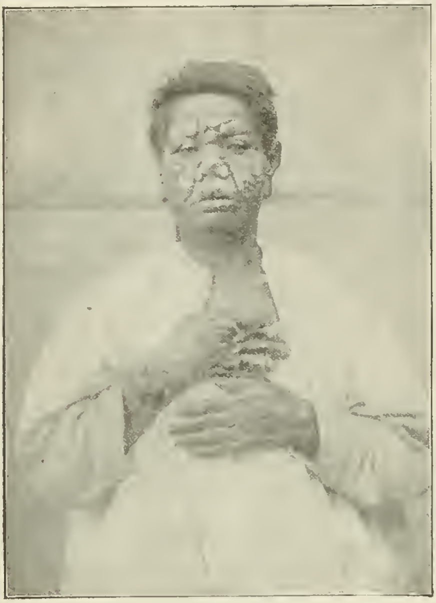
BALBEC, INDIANA,

LATE GOVERNMENT PHYSICIAN AND MEDICAL SUPERINTENDENT MATUTANI GOVERNMENT HOSPITAL, WAILUKU, MAUI, HAWAIIAN ISLANDS.

Leprosy is the name of a disease more terrible than it can be pictured even by the most sensational, and is so prevalent in the Sandwich Islands that the government has been forced to provide an island upon which the unfortunate victims could be permanently placed. The subject has been written and lectured about; made the theme for romance; and used by some to frighten timid strangers away from Hawaii. It was lately advanced as a reason why the islands should not be annexed to the United States. Leprosy is one of the most incurable, loathsome, and shocking diseases known to man. A reason why we dread the disease worse than we do other diseases is because its causation is still wrapped in partial obscurity. All unknown things are dreadful. While a specific germ has been discovered, it will not multiply out of the human soil in which it is found. We cannot trace a particular case back to a certain infecting source. We do not know how long the victim stays well after the germs get into him, or how long it always is before he shows the effects of their work in his system, or exactly what the earlier manifestations of the disease are. We are not able to cure the man. We doubt if he can be cured. One section of the medical world says that the disease is not contagious, and that segregation is therefore useless and cruel; the other, and we believe the more scientific party, says that leprosy is contagious, and that there is unassailable basis for the position. Granted that the disease is communicated by one person to another—how is it communicated? Do the germs fly, walk, swim, or smuggle themselves down our throats in food? Do they require special soils for growth? Must these be moist or dry; mucous membrane or blood? If the germs fly, they come in the dust from the street and carpet, circulate in the breeze, and leave us no escape. If they swim, they seek our milk and water, and so get into all foods. Do the mosquitoes, flies, fleas, and bedbugs bring the bacilli? We do not know; we only suppose. So the gnome of uncertainty glorifies itself, and we are ready to be alarmed. The disease has existed since the very earliest period of the world's history. Although Biblical writers gave the name of leprosy to several different diseases, some of them not specially severe, there were certain external changes in the skin and nutrition which made the disease resemble leprosy, at least to an untrained observer. The observers, not being specialists, took much for granted. Manetho, an Egyptian historian, who lived two hundred and sixty years B.C., says that ninety thousand Jewish lepers were expelled from his country. The Hebrew name for the disease meant a stroke or blow, and the description of Job's affliction is a fair picture of one form of leprosy. This places it some five hundred years further back, while certain papyri refer the malady to 4166 B.C. It prevailed in China, India, Africa, Phœnicia, Egypt, Arabia, Syria, Italy, and Greece in very ancient times, and from the second to the seventh centuries it was the common disease in Europe. Many persons used to cast their horoscope to see whether or not they were to be afflicted with leprosy. In 630 A.D. Italian law declared that lepers were civilly dead. Tamerlane caused them to be burned. Religious fervor had much to do with the spread of leprosy in Asia Minor, as in those days pilgrimages were made from one place to another. It is claimed that the Saxon pilgrimages spread the disease greatly. Lombardy was a leprous hot-bed. Leper hospitals began to be established in Great Britain and the Continent. In 1200 there were three leper hospitals in England, containing ninety-one inmates. Robert Bruce, of Scotland, died of the disease in 1329. Between the years 1100 and 1472 A.D. in Great Britain alone, there were established one hundred and eight lazarettos. It was even worse on the continent, where laws were passed for and against it, and one king "ordered lepers to be burned that their bodies and souls might be purified together." France built leper asylums in nearly every village, and in 1226 had segregated two thousand lepers. So numerous were the victims that the special religious order of St. Lazarus was organized in Palestine in 336 A.D. to care for them. Some of the leper institutes became very wealthy and influential. Norway, Sweden, Denmark, Germany, Russia, and Iceland suffered from the ravages of the advancing scourge, while Spain, Portugal, Madeira, and the Canary Isles were not immune. It is supposed that, until the arrival of negroes from Africa, America remained free from the disease. If the American Indian came from Asia, he had successfully left leprosy behind. In 1300 the disease began to abate in England, then in Scotland, where it limited itself to the isle of Papa, continuing there until 1740. In the sixteenth century hardly any lepers were to be found in France or Italy, the few cases there being in the Pyrenees. Leper houses were abolished in Denmark during the same century, but remained in Sweden until the eighteenth. In Norway the disease is still found. Why, the scientists cannot say. A distinguished leprologist writes:

"Within a few centuries of its first spreading into these countries, it had multiplied to such an extent as to have inspired the whole of Christendom with horror and fear. The disgust and terror which it evoked roused the whole population of these parts to drive the unfortunate lepers from their midst. The genius of Christianity, fortunately, was true to itself, and tempered this act by providing houses for the reception of the unfortunate outcasts. With extraordinary rapidity, considering the nature of the infirmity, it began to disappear simultaneously with the adoption of the strict measures that were put in force, the disappearance being as rapid and complete as the onset of the disease amongst the populations had been swift and intense."

The disease still exists in more countries than the general reader would imagine, being found in all the states of Europe, excepting Great Britain, Holland, and Denmark. Norway has quite a large number of her people segregated by law. But Asia is the great home of leprosy, British India having nearly one hundred and twenty-five thousand cases. There the sick and well mix without regard to care. This indifference and the prevalence of the malady are significant. Many of the English physicians do not "believe in the contagiousness of leprosy," which opinion does not seem to have any bad effect on the microbe. In regard to numbers China ranks next. Dr. Cantlie says: "Leprosy is endemic in every district in China, and the Chinese dread lepers and avoid them systematically, or expel them from their midst." Next follow Africa, Japan, and the islands of the Pacific Ocean. In Japan, the probable aborigines, the Ainos, who do not associate with the Japanese, are free from leprosy, while it is common among the latter. Other places where it is found are the states of South America, Australia, New Zealand, Mexico, Central America, and the West Indies. In New Brunswick there has been an average of about thirty persons confined in the lazarettos. In Louisiana in 1891, seventy-five cases were reported; about one hundred in Minnesota (Norwegians); many in California (Chinese); and sporadic cases occurring in South Carolina, Wisconsin, Michigan, Oregon, Texas, Maryland, Illinois, New York, and Nebraska. Between 1876 and 1886 ten persons died of leprosy in Minnesota. In all the States, excepting California, Louisiana, South Carolina, and Maryland, the disease was brought mainly by Norwegians, and is largely confined to them; while in California, of the fifty-two patients received into the hospital during ten years, all save one were Chinamen. In the Southern States the persons affected are negroes and Acady French.

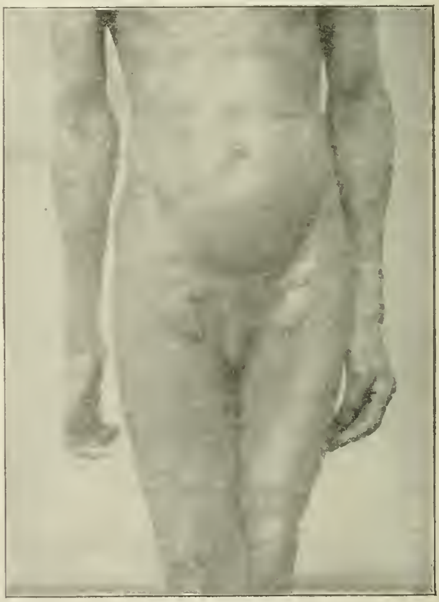


Man with Tubercular Mutilation.

This is not a place for a description of the symptoms of the disease. It is enough to say that its earliest manifestations are insidious, and largely unrecognizable at present; that it is progressive, persistent, and fatal. The one disease has two phases, nervous and tubercular, according as the germs find their home in the nerves or in the skin, with paralyses, contractures, and anæsthesia in the one case, and tubercular swellings and ulcerations in the other; with final mutilation in both.

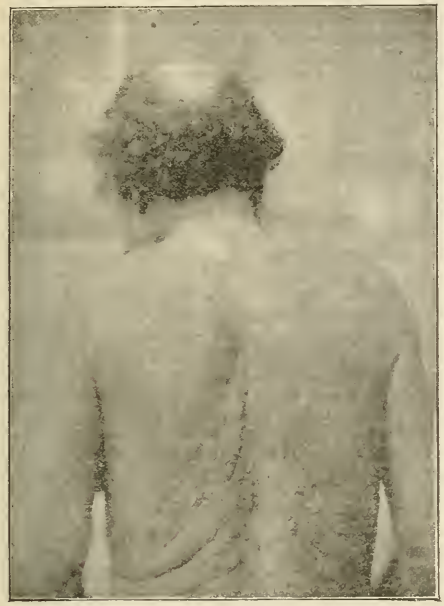
The two forms of the disease may exist in the same individual at the same time, and often do. It is most common in men, from the ages of fifteen to thirty years, but it attacks all classes at all ages. It may terminate fatally in one year, or run a course of thirty years, but its average lease is about thirteen years. The best authorities are agreed that the disease is contagious; that is, transmissible from one person to another.

The history of the disease in all countries, and among every class of people, points to the certainty of contagion. It has been traced to sources. Its course has been progressive when segregation has not been enforced, and retrogressive when it has. In proportion to the failure to carry out segregation, the disease has advanced. Families which in England are and have been free from the taint of leprosy, go to India, China, or elsewhere where leprosy prevails, and become leprous. Dressers, nurses, and physicians in leper hospitals contract the disease quite frequently. To Louisiana the disease came with some French settlers; to New Brunswick with Frenchmen; to Minnesota with Norwegians, and so on. In each location where the disease developed, carriers had come from leper-infected places. It can be traced back as certainly as we trace our individual characteristics. For this reason it was supposed to be hereditary and congenital. As in tuberculous disease of the lungs, there is no doubt a tendency transmitted, a peculiar make-up furnished, which is more susceptible to certain specific inoculations. I think that this is evident in the Polynesian. Its members readily acquire leprosy, and the tendency is increased by their habits of life.



Case Showing Swollen Glands.

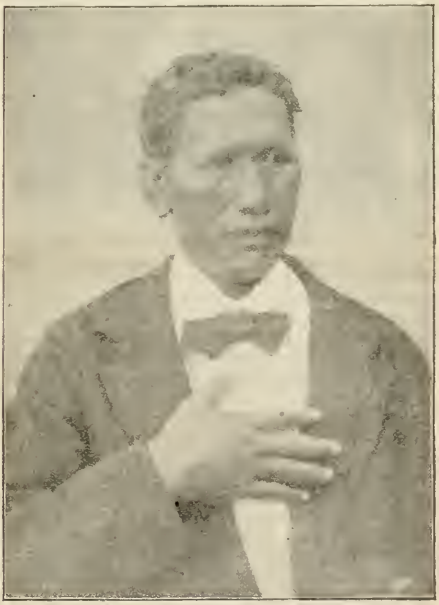
The causes of leprosy have been variously stated. Some have said that eating fish, fresh or salt, was a cause, citing Norway and other sea-washed countries where leprosy abides. It requires a long, tedious, painstaking series of observations and experiments, a peculiar mental attitude, and much particular knowledge to be able to trace accurately the relations of cause and effect. Without this necessary equipment, the most honest inquirer is very apt to fall into grave error and draw false conclusions. So leprosy has been attributed to the eating of pork, maize, spoiled rice, salt, olive oil, cheese, intoxicating liquors, awa drinking, and "moral emotion." The differentiation of the germ peculiar to leprosy, the bacillus lepræ, has set at rest much discussion, but as yet the microorganism will not show us how it works outside of the human body. Dr. Arning, who came from Germany to Hawaii at the request of this government, very carefully and conscientiously carried on some experiments, and was successful in inoculating a convict with the bacillus. The patient afterward died of leprosy. But, as he was a native, he may have had the disease in an incipient stage. Dr. Arning, with commendable conservatism, considered his experiment inconclusive. Dr. Fitch, an American quack who came there during the reign of Walter M. Gibson, took the kingdom by storm with his brilliant methods of treating disease. He had gone to an Eastern medical school, the University of Pennsylvania, where he was seen at lectures for two years, leaving before the examinations of the second year, on account of his aunt's advanced age and feebleness, entering the last year of a Western school. Here he got through by the skin of his teeth. But he always liked to talk about the University of Pennsylvania, the colors of which he wore. He began in Hawaii as physician to the Honolulu dispensary, where he had three large bottles labelled only with a number. From these jars the doctor supplied the natives with whatever they wanted in the line of treatment. If a patient came in, Dr. Fitch took a look at him, and called out to his assistant to fetch a ladleful of Number 335, which he administered to the dazzled native. Crowds began to pour into the office. Crutches were hung outside of the door; the poor, the halt, the blind, the deaf, thronged the portals, and twice a day the glass jars had to be replenished. Dr. Fitch was one of those men who, suddenly coming across an idea, catch it up in a hurry, run off with it, and never wait to see whom it belongs to, where it fits, or how it can best be used. Its antecedents were nothing to him. Correlation be damned! He took up his idea and began to blow it up, until—it collapsed. He read very little medical literature. He had a horror of theoretical men, laying great stress on practical work; forgetting entirely that an ignoramus and a fact are incompatibles. He used medicines, like a great many others of his tribe, not because they were indicated in a particular case, but because they had helped such and such a case. This he called his "experience," which he set up against the theory of all the text-books. Unfortunately for America, there are several such men around loose; men who ought to be chopping wood. Well, in that strange age, when the wisdom and honesty ledges had all panned out, King Kalakaua saw the diamond-cut-diamond he had in Dr. Fitch, and made him superintendent of the leper branch station, because the doctor said, just as positively as he said other things he didn't know, "Leprosy is only the fourth stage of syphilis." But he didn't deceive Drs. Emerson and Arning, and others who had been in Hawaii over two years. The following reports of cases are taken from some clinical data Dr. Fitch took the pains to secure:



Appearance of Back in an Advanced Stage of the Disease.

"Kine. Female, aged eighteen; sick four years. Is the last born of seventeen children, all dead, by a strong, fat, short mother and a tall, slim father, both living.

"Kahoe. Female, aged twenty-three; sick eighteen months. Had lived, ate, and slept together with her mother-in-law, who was a leper."

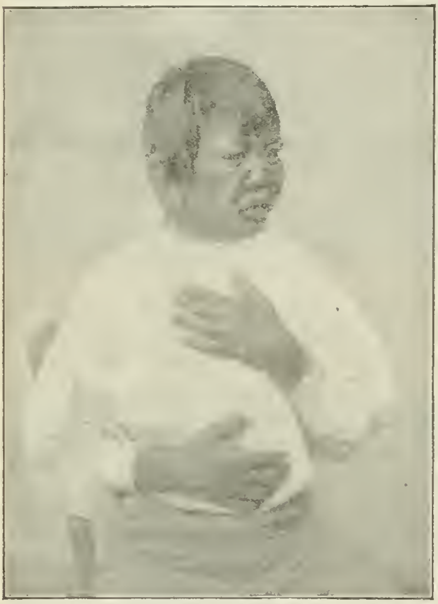


Showing Characteristic Swellings on Cheek and Hand.

Vaccination has been blamed for the spread of leprosy, but without good reason. It would be as impossible to prove that vaccination produced a particular case of leprosy, as to prove that it was Dr.

Arning's inoculation which caused the leprosy that followed. Either might cause the disease; and so might a mosquito bite. The predisposing causes are clearer: Filth, promiscuous tenantry, want of air in sleeping-apartment, scurvy, diet, and alcoholic beverages, anything which lowers the normal standard of health.

The first leprous man in Hawaii who came to the notice of the general public was a native named Kaea, who died in 1852, after being a leper for about ten years. His case was reported by Dr. D. D. Baldwin, of Lahaina, who in 1863 discovered that there were fifty leper communicants in his church. He was a physician as well as a minister. The same year Dr. Hillebrand, surgeon to the Queen's Hospital, wrote: "I wish to bring to the public's notice a subject of great importance. It is genuine, Oriental leprosy. Repeated investigations leave but little doubt in my mind about the contagious character of the disease, as I have followed its gradual spreading from a single person to many people in the same village. It will be the duty of the next legislature to devise and carry out some efficient, and at the same time humane, measure by which the isolation of those affected with the disease can be accomplished."



The Face and Hands in a Marked Case.

The disease was called "Mai pake" by the natives, and this meant Chinese sickness. In April, 1864, the board of health appointed Mr. Jourdan to take a leper census, and report the same. It was found that a surprising number were about the country, and that the contagion was being rapidly disseminated. The matter was discussed, and in January, 1865, the king signed an act providing that certain lands "be set apart," for the "isolation and seclusion of lepers"; that the board of health or its agents "be authorized and empowered to cause to be confined all leper patients who shall be deemed capable of spreading the disease of leprosy." Arrangements were then made for the "establishment of a hospital where leprous patients in the incipient stage may be treated." Dr. Baldwin sent his note of alarm from Lahaina: "We are beginning to have a crop of leprous young children."

One thousand dollars was now appropriated by the board of health toward defraying the expenses of Dr. Hillebrand, who went to China and the East Indies to investigate the subject of leprosy, while $30,000 was allowed for general expenses at home. In October of this same year, a "receiving station" was established at Kalihi, with Dr. Hoffman as resident physician. Dr. Hutchinson then selected and purchased the land upon which the present leper settlement is located. It is a portion of the northern part of Molokai, as effectually separated from the mainland as if it were separate island. It includes some five thousand acres, and a very fertile valley called Waikolu. The ocean washes three sides, while the south side, or base, is separated from the body of the island by a steep precipice, in some places nearly three thousand feet high. On each side of this peninsula, east and west, is a little village forming the unfortunate colonies.

The assessors of the islands were required to gather not only taxes but the sick, and send them from the various islands to Honolulu. One hundred and forty lepers were sent to Molokai in 1866, and during the three years following over $81,000 was spent by the board of health in carrying out the law of segregation. In 1873 more active measures were taken to segregate. Bill Ragsdale, a bright but dissipated half-caste, to whom reference is made in Mark Twain's book, voluntarily surrendered himself, and went to Molokai as superintendent of the settlement, where he did satisfactory work for the board. A boat was secured to carry provisions to the settlement. New taro patches began to be cultivated by the lepers, making it much more satisfactory both for the government and for the colony. During this year the Evangelical Association adopted resolutions advocating "more effective measures, or our Hawaiian people will become a nation of lepers." Between 1881 and 1882 the estimated number of lepers in Hawaii was four thousand. Of one hundred and fifty-seven lepers in 1866 two were Germans, two Americans, twelve Chinamen, and one was English. Dr. Arning said in 1866: "Among the white population, numbering 17,935, I know of thirty-five leprosy cases."

There are at present seven hundred and sixteen buildings in the settlement on Molokai, six hundred and nine being hospital, offices, schoolhouses, residences of officers, churches, a Young Men's Christian Association building, and bath houses. The Baldwin Home comprises a group of fifty-one buildings, and the Bishop Home ninety-eight buildings. There are Protestant and Catholic missions, while the Franciscan Brothers and Sisters have the "homes" in charge. The board owns cattle, horses, mules, and asses to the number of some seven hundred. There are now living in the colony 1,100 lepers, 625 males and 448 females. Of these 984 are Hawaiians; 62 half-castes; 37 Chinese; 5 American; 4 British; 4 Germans; 6 Portuguese; 2 South Sea Islanders, and 1 Russian.

During the past two years fifty-four children were born to leper parents. Kapiolani Home, a place for the care of girls of leprous parents, managed by the Sisters, adjoins the receiving station. The dedication of this institution was the occasion for a speech by his excellency W. M. Gibson, which was afterward embodied in a special report. A long array of highnesses and excellencies were present. Mr. Gibson was a spouter. "It may be mentioned in this place that as a delicate compliment to the Kapiolani Home, which was to be opened formally by her majesty, the king and queen, his excellency W. M. Gibson and Colonel Judd, the king's chamberlain, wore the star of the Order of Kapiolani. His excellency Mr. Gibson also wore the star and the ribbon of Pius the Ninth." Never was it worn by a more pious fraud. All this majesty, excellency, and Potiphar-chamberlain-butler business was in a little dark-skinned kingdom, with Americans at court. Think of it! Mr. Gibson then began to speak in his effervescing way:

"Your Majesties, Your Royal Highnesses, My Lord Bishop, ladies and gentlemen" [thus the minister of the interior, chairman of the sanitary committee, president of the board of health, began], "the memorable occasion which unites us to-day marks another day's advance in the onward march of the Hawaiian kingdom on the highway of humanity and civilization." [The Highnesses were smiling with pleased appreciation.] . . ."My task is ended, but let me add a few words. Hawaii has taken her stand among the nations" [since the Premier arrived] "and the nations of the earth honor our king and this kingdom for the attitude we take."

Then the official report goes on: "His excellency Mr. Gibson then stepped forward and presented the keys of the Home, attached to a gold chain and ring, on a crimson velvet cushion," while the highnesses, excellencies, chamberlains, and other people made obeisance. With all his talk Mr. Gibson delayed the good work of segregation, and during the time that he was president of the board of health very little effective work was done. When, later on, Dr. Emerson and others took up the health matters of the country, it was with added difficulty. It is said that only by great presence of mind, on one occasion, was the doctor able to save himself from the assassin's bullet. Some natives had come to kill him for carrying out the obnoxious law. It was the sad fate of Dr. J. K. Smith to die by the hand of a man whose wife the doctor had ordered to Molokai. Dr. Smith was a man of quick sympathies and warm impulse. He appreciated the pathos of these separations, even between natives, who, probably, are not so deeply sensitive to such events as we would be; and, I am sure, made the way as easy as he could for the poor mother who is torn from her babe, or the fond father who must let his only child go from him forever. Every one is familiar with the graphic picture in "Ben Hur," of the leper mother and sister; that story cannot be more pathetic than many of the incidents which are brought to a government physician's notice.

It will be seen, from what has been stated so far, that there is almost less danger to the average reputable foreign resident here, so far as leprosy is concerned, than there would be in other parts of the United States. To begin with, he expects to see lepers, and therefore knows how to avoid them. If he should not be able to recognize the disease, which is improbable, others will do so for him. As soon as a leper becomes known, he is isolated. If a man with a contracted finger or a suspicious face is seen, he is avoided. Examinations are made in schools and elsewhere, by physicians, and servants and nurses are usually selected with care. I never let a servant enter my house unless he or she be free from any taint of syphilis, leprosy, or other contagious disease. Food sources are looked into; water is boiled and filtered, and, in our home, the milk is all boiled as well. Everybody is on the *qui vive*, as it were; not fearful, but careful. These same precautions ought to be taken on the mainland east of us, against both leprosy and pulmonary consumption. Here physicians all recognize leprosy. In most of the States it is very different. Although there are a great many cases distributed throughout the States, there is no law to prevent its spread. A white leper may go from here and travel in any American city unmolested. He not only can, but does. Physicians there, looking upon it as a rare disease, do not recognize it except in its grosser forms. They do not expect to see it, and the laity have not the faintest idea what a leper looks like. I remember we had a leper in quite an advanced stage of the disease, at our clinic in Chicago. He had wandered about the country for four or five years, staying wherever he had money to pay his way, and no doctor had been able to tell him what his trouble was, until he reached Chicago. There are lepers in the North, from Oregon to New Brunswick, and in the South, from Central America to South Carolina, travelling criss-cross, with no one to say them nay. The thought is startling when we consider that these unfortunates can travel without being recognized as lepers. I once saw a man in a New York hotel, where he was a regular guest. I didn't know it then, but I know now that he was a leper; and I feel certain that none of the other guests knew what ailed the man. A specialist in the West speaks of having under his treatment in Nebraska a father and daughter who are lepers; while one of the ablest authorities upon diseases of the skin says: "It is not generally known, but it is a fact, that one of the most distinguished clergymen in the United States has been a leper for years."

Dr. Hyde of Rush Medical College says: "In its prodromic periods, no suspicions of its existence would be awakened in countries where the disease is not endemic. In this country, where leprosy, in consequence of its comparative rarity, has not yet awakened the attention of legislators beyond the point of forbidding the importation of infected persons, the proper care of lepers in a community only too ready to take alarm at even the name of the disease is a serious matter." I desire to call the attention of our legislators to this fact. It is high time that some steps be taken toward segregating all the lepers now on the mainland, and providing them with the comforts and medical care they need.

The proposal of the San Francisco authorities to place California lepers in the Hawaiian settlement should be considered, now that Hawaii has become an American possession. While Hawaii was an independent republic, its government very justly resented such a proposal, but now the removal of all our home lepers to Molokai would be the safest and most humane action that our government could take. It would work no injury to any one, reduce the danger of contagion to a circumscribed area, and cost little more than the maintenance of the Hawaiian colony. Besides, the territorial government of Hawaii is the only administration capable of caring for the lepers. It has capable, honest, sympathetic officials, who have learned by long experience just what to do for the settlement, and it has able physicians and experimenters who are carefully watching all the phases of the disease. To a normal person of intelligence and moral and social discrimination, I should consider, so far as the danger of acquiring leprosy is concerned, that Hawaii, or any other country practising segregation, offers substantial advantages.

Dionin (Ethyl-Hydrochlorate of Morphine).—Heim, who has studied the effects of this new drug upon a large series of patients, concludes that dionin is quite a useful preparation, whose action as an anodyne, hypnotic, and sedative places it between morphine and codeine and entitles it to a more general use. A habitus is only exceptionally acquired. Excepting in diseases of the heart muscles, disagreeable effects are usually absent. Administered per rectum, its action is as prompt as when given per os.—*Cf.* original article in *Klinisch-therap. Wochenschr.*, 1899, No. 46.

SANATORIUM TREATMENT AT HOME FOR PATIENTS SUFFERING FROM TUBERCULOSIS.[1]

By S. A. KNOPF, M.D.
NEW YORK.

THIS title in itself will tell you that I have no new antituberculous remedy to offer. Even the system of treatment, to which I have to refer frequently, is not new. Many,[2] and myself among them,[3] have described the typical sanatorium treatment for consumptives before. The only excuse I have for appearing before you is my hope that what I have to say of the system as applicable by the general practitioner in the house of the patient may arouse an interesting discussion from which we all cannot fail to profit, and through which the cause of modern phthisio-therapy will certainly gain.

Years of study of the treatment of consumptives in special institutions have made me an enthusiastic advocate of this therapeutic system. The insufficient number of sanatoria in proportion to the number of consumptives has led me to treat many a patient as best I could by imitating the sanatorium treatment at home. But before detailing what might be done under such circumstances, let me rapidly enumerate the essential factors of the typical sanatorium treatment.

There is, first, a so-called general hygiene; second, a special hygiene; third, an excellent table; fourth, an arrangement for the open-air treatment; fifth, a hydrotherapeutic establishment; and last, but not least, the constant medical supervision of the patient.

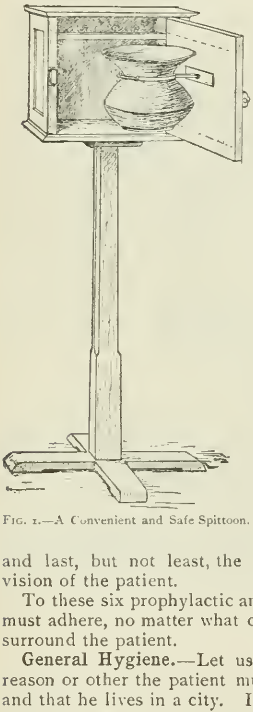


FIG. 1.—A Convenient and Safe Spittoon.

To these six prophylactic and therapeutic factors we must adhere, no matter what climatic conditions may surround the patient.

General Hygiene.—Let us presume that for some reason or other the patient must be treated at home, and that he lives in a city. If he has not a home of his own he will probably consult his physician as to the best place for a residence. I would tell him to try to live in the highest portion of the city; to seek as quiet a neighborhood as can be found, where there is relatively little traffic. If the patient can reside in the outskirts of the city on high, non-malarial ground, so much the better. The largest, sunniest, quietest, and best-ventilated rooms, preferably on the second floor, so as to avoid the fatigue of climbing stairs, should be selected for the patient. If the dwelling is a modern apartment house with elevator, the top floor, of course, would be the best of all for our purpose.

In the room mainly occupied by the invalid velvet or plush covered furniture should be replaced by such as will not accumulate dust. Raising dust by sweeping with a broom should never be allowed in any sick-room, but particularly not in one occupied by a pulmonary invalid. A moist mop should be used to remove the dust from the floor, and the furniture should be wiped carefully. The carpet, heavy curtains, and superfluous furniture should be removed, without, however, leaving the room cheerless. Small rugs and curtains that can be washed may be retained.

A tuberculous patient should always sleep alone and in a bed which should be freely aired during the daytime. A very weak patient who does not leave the bed should, whenever it is possible, have a second bed placed in his room so as to be able to change. A brass or iron bed, with wire mattress, is preferable. Feather beds should not be used. The bed should be placed with the head against an inside wall. Drafts should be avoided as far as possible, but this precaution must not be carried to extremes so as to make the patient afraid of a breath of fresh air. If the bedroom is too small to make it possible to place the bed so as to avoid the direct draft from the open window, a substantial screen should be used as a protection.

Under the heading of general hygiene is comprised, of course, sanitary plumbing, a sufficient supply of pure cold and hot water, and for heating purposes an open fireplace whenever practical. The patient should be guarded against the unwholesome influence of the very dry heat which comes from the furnace in the average American home. Some humidifying arrangement (evaporating pan, Barnes humidifier, etc.), whereby the air may be kept moderately moist, should be used.

Special Hygiene.—The special hygiene deals with the careful disposal of the sputum and other secretions which may contain the bacilli; the care of the patient's linen, and finally his clothing and manner of dress.

To an audience of physicians and sanitarians there is no longer need to speak of the importance of the precautions to be taken with the tuberculous sputum, and I shall confine myself simply to the description of a few utensils which I think indispensable in a private home, hospital, or even dispensary for consumptive patients. They are to my mind the best means to stop the propagation of tuberculosis through carelessly deposited tuberculous expectorations.

Here is an ordinary enamelled iron spittoon. To make sure that the patient always hits it, I recommend this simple stand which is elevated three feet from the ground (Fig. 1). The cuspidor is supported by a metal ring attached to the door of the cupboard. The patient desiring to expectorate opens the little door, thus bringing the spittoon within his reach, and closes it again when he gets through. An automatically closing extra cover makes it impossible for flies and other insects to sojourn in the interior. With this arrangement there is no excuse for not being able to hit the spittoon and thus soiling the brim. The unpleasant appearance of numerous spittoons placed on the floor, in places where much expectoration is going on, makes the elevated spittoon preferable from an æsthetic as well as from a hygienic point of view. The cuspidor of metal, elevated and covered, has additional advantages over the usual uncovered vessel of porcelain or earthenware. Animals, such as dogs, cats, etc., will not be able to reach the contents of the cuspidor; and there is less danger of its bursting when placed outdoors at freezing temperature if covered and enclosed in a box. Again, I prefer metal spittoons to glass or porcelain, because the persons entrusted with cleaning them are not exposed to the possible danger of inoculation by breakage.

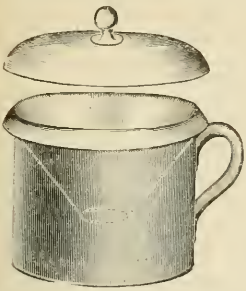

Fig. 2.—Aluminum Spit-Cup for use at the Bedside.

For a patient confined permanently to his bed I think this plain aluminum cup with cover answers all practical purposes. It is light and easily cleaned (Fig. 2). It has the additional advantage of not having the typical aspect of a spittoon. This as well as all other stationary cuspidors should be filled to about one-third with some antiseptic solution, preferably wood vinegar. For those who can conveniently destroy the sputum by fire, Seabury & Johnson's well-known paper spitting cup is a handy and useful utensil. I take pleasure in showing it to you in its new form with an aluminum frame and cover (Figs. 3, 4). Patients who are too weak even to make use of this light aluminum cup should have at their bedside a number of moist rags, which should be burned immediately after use, or at least before they have had a chance to dry. For the patients who are up and around and who go outdoors the pocket flask is the only rational utensil to receive the expectoration. There exist a number of them. I have described the celebrated Dettweiler pocket flask (Fig. 5) and also my own (Fig. 6) on several occasions before this. I have given detailed descriptions and illustrations of these and others in my recent book on tuberculosis,[1] and I fear to trespass on your time to say any more about them. I show these two to you, and confess frankly I consider neither of them perfect. I hope some day to be able to present you an ideal pocket flask, but I think that either of these will answer the purpose in the mean time.

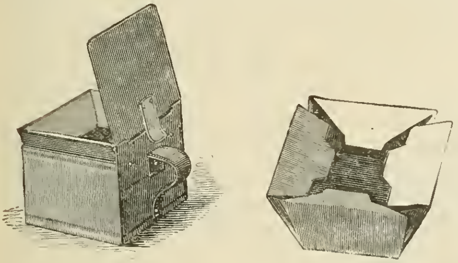

Fig. 3.—Frame. Fig. 4.—Folded Cardboard.

Seabury & Johnson's Spitting-Cup.

To encourage the use of the pocket flask one must make its manipulation and the process of cleaning it as simple as possible. I direct my patients to empty the flask into the water-closet or to fold a newspaper into several layers, pour the contents on to this, and throw the whole at once into the fire, being careful not to spill any. One should, however, not forget to insist that the patient washes his hands carefully afterward.

Larger quantities of tuberculous sputum, collected from the spittoons, should be gathered in a separate pot partially filled with water and the whole be boiled for half an hour. To increase the boiling-point a few degrees, a teaspoonful of soda might be advantageously added for each quart of liquid.

Some consumptive individuals will not use the pocket flask in spite of all persuasion, for the simple reason that they do not wish to attract attention to their malady. For these there is but one thing to do—to tell them to use squares of muslin or Japanese paper handkerchiefs specially manufactured for that purpose, which can be burned after use. But I should insist that they place in their pockets a removable lining of rubber or other impermeable substance which can be thoroughly cleaned. This additional pocket could be fastened to the inside of the ordinary pocket by clamps, and thus be of no inconvenience to the patient. Of course, all individuals using handkerchiefs as receptacles for sputum take their chances of infection through contact with the expectoration, and they should be particularly enjoined never to touch any food without having thoroughly washed their hands.

The soiled linen of consumptive patients should be placed in water immediately after removal from bed or body, and be handled as little as possible before that. The handkerchiefs especially, even if they have not been used to receive expectoration, should be washed separately or at least boiled before being given to the general laundry.

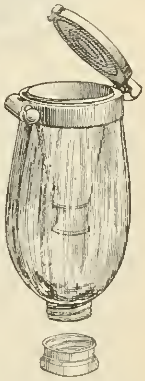

Fig. 5.—Dr. Dettweiler's Hustenflaschchen.

In the private home, with loving friends and relatives about the patient, everybody should be told that kissing on the mouth is unhygienic. The saliva of tuberculous invalids is certainly not free from bacilli. If the patient cannot have his own table utensils, as forks, spoons, glasses, etc., it is well for the physician to insist that all these utensils shall be placed in boiling water for a few minutes each time after use. In view of the undeniable fact that during the dry cough, or while speaking loudly, small particles of tuberculous sputum or saliva can be expelled, the patient should be taught to place a handkerchief before his mouth during the dry cough. The danger of infection from these small particles of saliva expelled while talking is, however, relatively small, since the number of bacilli found in the minute drops of saliva are few, and the little masses are never expelled beyond three feet from the mouth of the patient.

---

[1] Knopf, S. A.: "Pulmonary Tuberculosis, Its Modern Prophylaxis and the Treatment in Special Institutions and at Home." Philadelphia: P. Blakiston's Son & Co., 1899.

In hospitals where many advanced consumptives congregate, the precaution to have the patient wear Professor Fraenkel's mouth mask is doubtless of utility and constitutes justly one of the modern measures to prevent the spread of tuberculosis. I take pleasure in showing you here such a mask, the mechanism of which is easily understood. At the Charity Hospital in Berlin all tuberculous patients are obliged to wear such masks when in the common room, and only remove them while eating or expectorating. The patients soon become accustomed to the mask, as by impregnating the gauze, which is held in place by the metallic frame, with some medicinal substance they suppose it is to be worn exclusively for their own personal benefit. Bacilli are not infrequently found in the gauze. It is, of course, self-understood that the gauze, lint, or cotton removed from these respiratory masks should be burned immediately, and the masks disinfected at regular intervals.

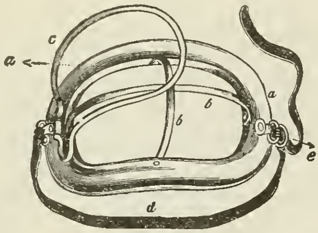

Fig. 8.—Professor Fraenkel's Mouth-Mask.

I hardly think that in ordinary private cases the wearing of such a mask is practical or absolutely necessary; but I would instruct nurses, relatives, and friends who are much with the patient not to approach him unnecessarily close while he is speaking or coughing, or for any length of time.

As far as dress for the tuberculous invalid is concerned, we might summarize the whole subject by saying that he should dress sensibly, comfortably, and according to the season. He should avoid heaping successive layers of underclothing upon himself, especially in the line of chest-protectors. As underwear, Jaeger's or other similar sanitary wool suits of the lighter or heavier grade, according to the season, are to be recommended. In cold weather the outer garment should be warm, but not so heavy as to hamper free movements. For ladies I recommend the Lady Habberton or Jenness Miller system of dress reform, which does away with the corset and the numerous skirts fastened tightly around the waist, and, last but not least, the unclean and unhygienic mode of long trailing dresses. The footwear of all phthisical patients should be warm, but never tight, and in wet weather, of course, they should wear rubbers. As a matter of personal hygiene I might suggest that long beards or thick untrimmed mustaches are often retainers of particles of sputum and thus may constitute a source of infection. Whether we may allow our patient occasionally a cigar will depend upon the individual case. I never permit the smoking of cigarettes, and, of course, it is out of question to allow smoking in the sick-room.

Dietetic Treatment.—We now come to the patient's diet. My distinguished teacher in modern phthisiotherapeutics, Herr Geheimrath Dettweiler, is in the habit of saying, "La cuisine est ma pharmacie." This maxim is as appropriate for the private practitioners who treat consumptives as it is for the sanatorium physician. When we have to treat our patient at his own home we must not only have a good table for him, but our cooking-recipes and directions concerning his diet must be carried out as faithfully as if we had prescribed a medicinal mixture. A fair understanding of how to prepare good nutritious and easily assimilated food for invalids is indispensable to every physician, but especially so to the phthisio-therapeutist. I hope the time is not far distant when instructions in the principles of cooking for the sick will be included in the curriculum of our medical schools. We all know the importance of dietetic treatment in pulmonary tuberculosis, but we are not always aware of the difficulties which we encounter when the patient is in his own home and has something to say about the daily menu. His aversion to fats, his not infrequent dislike to take larger quantities of milk, or other caprices regarding the preparation of food or the time of taking his meals, are matters which must be overcome; otherwise the successful treatment of a consumptive at home is an illusion. Certain conditions of anorexia will often yield more rapidly through the aid of the culinary art than through the administration of pharmaceutical preparations. While we may consider the patient's idiosyncrasies for certain dishes as well as for certain medicines, we must know how to distinguish idiosyncrasies from caprices. One important truth that he should be made to understand is, that his digestive powers are far greater than his appetite indicates.

I will give here briefly what I consider an average régime for a consumptive accustomed to our American way of living. As soon as the patient awakes in the morning, while yet in bed, a glass of hot milk, half milk and tea, or half coffee and milk, with a slice of milk-toast, should be given him. After a little while he will rise to prepare for his douche, friction, or massage, whatever the physician's prescription may call for. After this it will probably be nine o'clock, and the patient may take his ordinary breakfast. He should have eggs, and may have his choice as to the way they may be cooked—soft-boiled, poached, raw, etc., or in form of eggnog, with sherry or one or two teaspoonfuls of whiskey. If he is accustomed to a meat breakfast, he should have broiled steak, chops, poultry, sweetbreads, etc., or raw chopped beef. Bread a day old—preferably whole-wheat bread or French rolls, but not hot—with plenty of butter or honey, either milk, cacao, coffee with milk, but not too strong, or a cup of bouillon, should also form part of the meal. Whether the patient likes to have his mush (cereals) for breakfast or supper may be left to his choice; some fruit should always precede his eggs or meat in the morning. If fish is served in the morning it should be either broiled, or boiled, or baked.

The patient should take the heartiest meal between the hours of twelve and two o'clock (four hours after breakfast). Broths or soups should be the first course. Oysters and clams are most easily digested raw. Any kind of fresh fish may be served again at dinner, and in any form except fried; and there will be, of course, roast meat of some kind, rare roast beef, mutton, poultry, etc. Of vegetables, spinach is particularly to be recommended on account of the large proportion of digestible and assimilable iron. Next to this in nutritive power come lentils, peas, beans, cauliflower, potatoes. Fresh vegetables should be given whenever it is possible to have them. Lettuce and other salads preferably prepared with lemon-juice instead of with vinegar, are permitted. Light puddings, fruits, and nuts may constitute the dessert.

At about four or five o'clock some milk with toast may be taken, or, if the patient cares for it, he should have a cheese or meat sandwich. At this time the milk may be replaced by bouillon or chocolate.

The supper should not be quite so voluminous as the dinner: cold or warm meats, rice with milk or gruel, jellies, fruits, etc. At bed-time again a glass of milk or some milk-toast.

It is, of course, impossible to lay down an absolute rule of what to allow and what not to allow. At times the patient may be permitted to indulge in such things as ham, smoked tongue, and even pickled or salt herring, sardines, or sardelles, as these articles seem to stimulate the appetite without producing any bad results. All bouillons and soups taken regularly at the principal meals aid the digestion by increasing the flow of the gastric secretions. Raw scraped beef is a most valuable adjuvant in the feeding of tuberculous invalids. It is always indicated, but especially when meats prepared in the ordinary way do not seem to be digested very easily. The supply of meat-pulp for the day may be made in the morning, but it must be kept in a cold place, as it taints easily. It is better, when possible, however, to make it fresh just before it is to be eaten. The patient may take the pulp in any way he pleases. It can be eaten plain with pepper and salt, mixed with milk, with warm bouillon, with mashed vegetables, or with sweets. The latter method will make it tempting for children. It can be rolled into balls easy to swallow, or made into sandwiches with a few anchovies or a little anchovy paste, pickled herring, or some other relish, according to the patient's taste. The yolk of a raw egg added increases the nutritive quality of the meat-pulp. Thus it will be seen that the ways in which the raw meat may be taken are so numerous that it can be made palatable to almost any patient.

To eat a great deal of butter and cream is especially to be recommended to pulmonary invalids, and milk should be allowed at any time without restriction. However, some patients, in their eagerness to get fat, overdo in this respect. When drinking numerous glasses of milk between meals interferes with the proper appetite at meal-times, the number of glasses should be reduced accordingly. Again, neither milk nor cream agrees well with some consumptives. To make the former more digestible, one may add to each wineglassful one-half or one teaspoonful of cognac, kirsch, or rum, with or without hot water. Milk may also be rendered more digestible by adding to each tumblerful about six grains of bicarbonate of sodium and five grains of common salt, dissolved in two tablespoonfuls of hot water. It should always be taken slowly and in small swallows.

Patients should be taught to eat regularly, slowly, chew their food well, and keep their teeth in good condition. When the weather permits, let them take their meals outdoors. A patient who has fever should eat when his temperature is lowest, and only the most easily digested substances. Alcohol is indispensable in some cases, but it should always be dealt out carefully and preferably in the diluted form of eggnog, wine, or beer.

Open-Air Treatment.—The open-air treatment, that is to say, remaining in the open air during most of the day, is essential if we wish to make our hygienic and dietetic treatment at the home of the patient a success. The patient's bedroom is, of course, always airy, and day and night one or more windows, according to the season, should remain open. Deep breathing is done as often as the patient thinks of it; regular respiratory exercises every half-hour or hour; these exercises should be taught gradually, and as often as it is possible they should be superintended by the physician. A good rule is to tell the patients never to take their exercises when they feel tired, nor to the extent of becoming tired.

The rest cure (or "Liegekur") on the reclining-chair is the most important feature of the open-air treatment. For that purpose the patient may install himself in the garden near the house, on the porch, on the balcony, roof, or fire-escape, or near the open window. For those who have the advantage of a garden, an installation, of which I show you here a picture taken from my book, might make an ideal rest-cure arrangement. A large beach-chair of wicker-work, such as is seen in seaside resorts, is procured. After the seat has been removed the inner walls are lined with padding. A reclining-chair is placed with its back in the interior, and the whole arranged so that the patient is protected from the wind and sun. There the patient installs himself for the day, with his books or writing materials at his side, placed on a little table, on which his meals may also be served. Being light, the whole can be shifted whenever the wind changes and according to the position of the sun, so that the invalid's body may be bathed by the rays of the sun, while the head remains in the shade. However, a plain steamer-chair, padded with a quilt or blanket, and a large umbrella will answer the purpose where such an installation cannot be arranged.

The length of time to remain on the reclining-chair outdoors must be regulated by the physician according to the weather and the condition of the patient. But the endurance at which the patient can arrive in this respect by gradual training is simply wonderful, and cold weather, when the patients are warmly wrapped up, should certainly not be a hindrance to a prolonged rest cure.

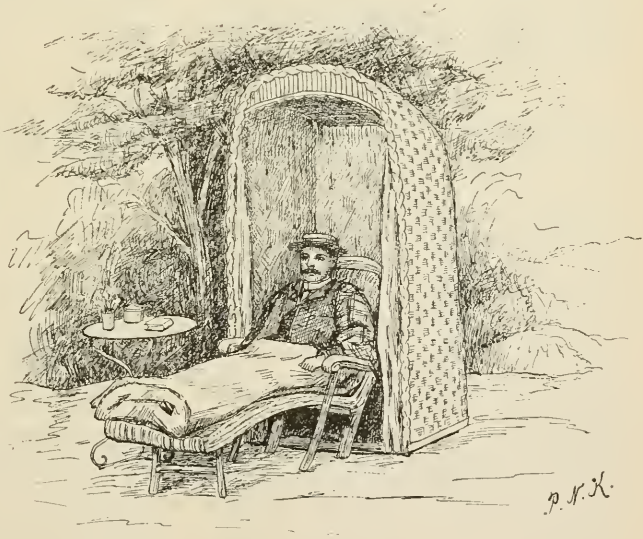

Fig. 9.

On the question as to whether or not we should allow our phthisical patients walking-exercises, even if they have fever, all phthisio-therapeutists do not agree. Let me state here briefly the position I take in this matter, which I have published before, and to which I still adhere. Rest cure should alternate with walking-exercises. The duration of a promenade for a phthisical patient should be regulated with the utmost care. One should commence with a walk of a few minutes until a walk of an hour or an hour and a half can be taken without producing fatigue. Whenever it is practicable these excursions should begin uphill, so that the return is easy. After his promenade the patient's temperature should be taken. If it exceeds the normal it is an indication that the patient has overtaxed his powers. Whether complete rest or simply shorter walks are then indicated will be decided by the variation of the temperature before and after exercise. When the temperature of the patient rises only slightly in the evening (99-99.5° F.), short walks in the morning, while in the apyretic state, may be permitted. A lasting temperature of 100° F. or over is an absolute contraindication to exercise. Tachycardia should also be considered as such. If there is, however, a chronic tachycardic condition, absolute rest might not be the best policy. But these patients, more than any others, should be warned against the slightest over-exertion. When the patient is ambulant, and you have a pneumatic cabinet in your office, a daily séance of from five to eight minutes will be a considerable aid in your efforts to make a partially solidified lung do its normal work again, for there is no doubt about the therapeutic value of this useful instrument. It has rendered me excellent services with the patients who could come to my office. My time will not permit me to speak here at length of the virtue of the pneumatic cabinet as a diminisher of vascular compression, alveolar and tubular obstruction, and a restorer of oxygenation. Those who are interested in the study of this subject I must refer to the excellent article of Quimby, "The Pneumatic Cabinet in the Treatment of Pulmonary Tuberculosis," which appeared in the *International Medical Magazine* for January, 1893.

Hydrotherapy.—The consumptive patients whom we are to treat at home will probably all have a bathroom where we can arrange to give a general douche as a tonic, a jet over the apices for the purpose of causing a revulsion, or a lateral douche in order to break up old pleuritic adhesions. In case there is no bathroom, or the visit to the douche-room is either inconvenient or not safe, I resort to the following simple method: A wooden chair is placed in a large, circular, English bath-tub, and the patient sits astride the chair, holding the back with his hands and bending his head slightly forward. Then two, four, or more pitchers of cold or tempered water are rapidly poured over the shoulders. In cases in which the reaction is feeble the patient is quickly put back into his warm bed, even if he is not thoroughly dry.

The best time to make the hydrotherapeutic application is in the morning, half an hour or so after a very light breakfast. Patients accustomed to heavy breakfasts should, as I have already mentioned, take such after their douche and morning walk, but should take a glass of milk with a slice of buttered toast before leaving their room. A morning walk should, if possible, always precede the douche. This is for the purpose of creating what French hydrotherapeutists call a preaction.

Every douche or affusion should also be followed by a short walk or return to bed, according to the indication of the case. The cold douche must never last longer than twenty to twenty-five seconds, and one should always begin gradually, not giving more than five seconds at first. The temperature may vary from 60° to 40° F.; only in exceptional cases would one need a more precise graduation of the temperature.

The complicated procedure of the dripping sheet seems to entail too great a strain on the patient, and I do not favor it in phthisio-therapeutics. Wet packs, on the contrary, over the thorax seem to exert a soothing influence whenever there are pleuritic or intercostal pains, or a vague or undetermined feeling of discomfort in the chest.

All hydrotherapeutic applications should be directed by the physician. He must educate the skin and nervous system of his patient to the use of the douche by the gradual application of the water through friction and affusion. He must teach his patient how to take an occasional warm or steam bath to eliminate the toxins without taking cold afterward.

Constant Medical Supervision.—The good results in sanatoria are to be ascribed to the constant medical supervision of the patient by the physician in charge, or his assistants, who direct all the details of the hygienic, dietetic, and symptomatic treatment. We must do the same if we want to institute a sanatorium at home. But there are a few points in the educational treatment of consumptives in which the family physician has the advantage over the sanatorium physician. The former can make his authority felt whenever there is a question of marriage. I admit that the families will not always listen to such advice; still I claim that in many instances marriage between tuberculous individuals could be prevented by an energetic protest on the part of the family physician. Another important issue, which will present itself more frequently to the family physician than to any one else, is the question of prevention of conception when either one of the married partners suffers from pulmonary tuberculosis. I have no hesitation to declare publicly my position in this matter. To cut short a conception in a tuberculous mother is useless; she has a better chance of getting well if left alone, and if a thorough dietetic and hygienic treatment is immediately instituted and prolonged for at least a year after confinement. Of course, it goes without saying that the tuberculous mother is not to nurse the child herself. Thus through a very judicious management two lives have a chance to be spared, while through abortive proceedings mother and child would most likely have succumbed. On the other hand, when it comes to the prevention of conception in a tuberculous woman, or from a tuberculous man, I believe it is the sacred duty of the family physician to teach these people legitimate means that they may not bring into life a being tainted with a predisposition to this disease. Furthermore, there is no doubt that the pregnant state in a tuberculous woman, while it may temporarily arrest the disease, causes in the majority of cases a more rapid decline after confinement. In view of our present knowledge of tuberculosis I do believe that to teach a tuberculous man or woman how to prevent conception is not a sin before either God or man.

The symptomatic treatment of pulmonary tuberculosis must be the same everywhere, and I have nothing new to offer. But I desire to say one more word in regard to the prophylactic treatment, which I admit I have also said on previous occasions, but which I like to repeat again and again.

The treatment of tuberculosis in the private home by the family physician should be prophylactic in the broadest sense of the word. It is the family physician who will see the incipient cases first; it is he who will discover a predisposition to phthisis when a wise and judicious treatment will save the patient. The intimate relation which exists between the family physician and all the members of the family give him here again the superiority over the sanatorium physician. The latter can help only the patient placed under his care, while the family physician can at the same time prevent the breaking out of tuberculosis among the other members of the family.

After all that has been said you will agree with me that the sanatorium treatment is feasible even in the average home, provided the patient's social and financial conditions permit the carrying out of a rigorous hygienic and dietetic regimen under the careful guidance of the family physician. But with the vast majority of tuberculous patients, and this majority constitutes the consumptive poor, to carry out successfully the precepts of modern phthisio-therapy without special institutions supported by the State or municipality, or private philanthropy, is utterly impossible. Thus you will pardon me if I conclude my paper with a fervent plea for a decided action on part of this society in the matter of the creation of public sanatoria —that is to say, institution for that class of sufferers who deserve the greatest sympathy, and through whose hospitalization the public health will gain most and the commonwealth be morally and financially benefited.

It was in our great State of New York, through the efficient and energetic work of my esteemed teacher, Professor Bryant, then health commissioner, and who now graces our presidential chair, that the combat against bovine tuberculosis was first taken up. The work of the New York City board of health, concerning the prophylaxis of tuberculosis in man, inaugurated a few years ago, has won the universal admiration of sanitarians in this country and abroad. But of late we have not kept pace with even our sister States, much less with foreign countries. Pennsylvania and Illinois have a society for the prevention of tuberculosis, with growing funds for the erection of sanatoria. Massachusetts has its State Hospital for Consumptives. New York, the most densely populated and richest State in the Union, with the greatest number of consumptive poor, has neither a society for the prevention of tuberculosis, nor a sanatorium, nor a State hospital. May the New York State Medical Association, in its last meeting in the nineteenth century, not adjourn without taking some active step in this important matter.

15 West Ninety-fifth Street

A CRITICISM UPON A NEW METHOD OF PREPARING THE SKIN FOR VACCINATION BY DENUDATION WITH CAUSTIC POTASH SOLUTION.

By FRANK S. FIELDER, M.D.,

NEW YORK CITY.

ASSISTANT DEMONSTRATOR OF ANATOMY, CORNELL UNIVERSITY MEDICAL COLLEGE; MEDICAL INSPECTOR, NEW YORK CITY HEALTH DEPARTMENT.

In a paper published April 23, 1898, in the *Journal of the American Medical Association*, Dr. Hutchins, of Georgia, recommended a new method of preparing the skin for vaccination by denudation with caustic potash as a substitute for scarification by the usual methods. The advantages which Hutchins claims for his method are, that it is painless; that it is not terrifying to the child because no instrument is used; that it causes no bleeding, and is for this reason more likely to be successful than when an instrument is used which draws blood.

Hutchins at first used the officinal liquor potassæ (a five-per-cent. solution of KOH in water), soaking a small pledget of absorbent cotton in the solution, letting it lie upon the arm for two or three minutes until the skin was denuded of epidermis, then wiping the surface with another piece of absorbent cotton dampened with water. Later he used the deliquescing stick of KOH, applying it to the surface for a moment only, and immediately wiping off the denuded area as before.

The experiments upon which this paper is based were performed by the writer in October, 1898. The cases vaccinated were all "primaries," *i.e.*, they had never been vaccinated before, and were twenty-two in number. The virus employed was in each instance controlled by using it upon other cases by the ordinary method of needle scarification. Different strengths of KOH solution were used, but none so weak as the officinal liquor potassæ.

These experiments are described in detail as follows:

Experiment 1.—October 4, 1898. Virus No. 510, collected September 20, 1898.

Control, October 4, 1898: One case vaccinated in three spots by needle scarification. Result, six days after vaccination: three good-quality, large, compound vesicles on large papules.

Experiment: Five children vaccinated in one spot each by denudation with KOH, as follows: Deliquesced KOH applied with a very small swab, made by rolling a bit of absorbent cotton around the end of a wooden toothpick. After it was evident that the epidermis was dissolved the denuded surface was wiped off with a swab of absorbent cotton dampened with water.

Appearance after denudation: In each case the denuded spot was slightly depressed and covered with a bluish or bluish-red eschar of a peculiar parchment-like appearance. No blood flowed.

Upon these areas glycerinated vaccine virus was smeared, then thoroughly worked in with the sharp corner of the broad end of an orange-wood toothpick, just as is done after scarification by the usual method.

Results, six days after vaccination: Case 1, good quality and size compound vesicle on papule; large dry scab from eschar. Case 2, small vesicle one-eighth inch in diameter at one edge of dry scab from eschar. Case 3, failed. Case 4, good quality and size compound vesicle on papule; moderate-sized dry scab. Case 5, good quality and size vesico-pustule on papule; moderate-sized dry scab (this case inspected at seven days). We thus obtained from five insertions four vesicles, three good and one very small, and one failure.

Experiment 2.—October 10, 1898. Virus No. 525, collected October 5, 1898.

Control, October 6, 1898: Five children vaccinated in three spots each by needle scarification. Result, five days after vaccination: Fifteen vesicles of good size and quality.

Experiment: Five children, vaccinated in one spot each with deliquesced KOH, as before; the spots then were washed off with dilute acetic acid to neutralize the KOH and stop further destruction of tissue if possible.

Appearance after denudation: Same as in Experiment 1.

Results, five days after vaccination: Case 1, good compound vesicle on papule; moderate dry scab, not depressed. Case 2, good compound vesicle on papule; moderate dry scar, not depressed. Case 3, failed (inspected again eight days after vaccination. No vesicle resulted). Case 4, good compound vesicle on papule; moderate dry depressed scab. Case 5, good compound vesicle on big papule; moderate dry depressed scab. We thus obtained from five insertions four good vesicles and one failure.

Experiment 3.—October 10, 1898. Virus No. 526, collected October 6, 1898.

Control, October 7, 1898: Six cases in three spots each by needle scarification. Result, five days after vaccination: Eighteen vesicles, as follows: nine of good quality and size; six of fairly good quality, fair size; three of good quality, fair size.

Experiment: Two children vaccinated in two spots each, one with needle as usual (A) and one with KOH solution, followed by acetic acid, as in Experiment 2, the KOH solution being somewhat weaker than in Experiment 2 (B).

Appearance after denudation of (B) spots: Same as in Experiments 1 and 2.

Results:

	A (Needle Scarification).		B (KOH Denudation).	
	Five Days after Vaccination.	Eight Days after Vaccination.	Five Days after Vaccination.	Eight Days after Vaccination.
Case 1.	Small compound vesicle on papule.	Fair compound pustule, moderate areola.	Failure . . .	Failure.
Case 2.	Small compound vesicle on papule.	Fair compound pustule, moderate areola.	Failure . . .	Failure.

We thus obtained: A (needle scarification), two fair vesicles; B (KOH denudation), two complete failures.

Experiment 4.—October 22, 1898. Virus No. 529, collected October 20, 1898.

Control, October 20, 1898: Five cases in three spots each by needle scarification. Result, five and six days after vaccination: Fifteen vesicles, fourteen of good quality and size, one of fair quality and size.

Experiment: Five children vaccinated in two spots each (A and B) as in Experiment 3, except that KOH solution was somewhat weaker than in Experiment 3, though still strong.

Appearance after denudation of (B) spots: Same as in Experiments 1, 2, and 3, except that eschars were perhaps not so thick.

Results, five days after vaccination:

	A (Needle Scarification).	B (KOH Denudation).
Case 1.	Fairly good quality and size, compound vesicle on papule.	Failure (seen also at thirteen days, failure).
Case 2.	Good quality, fair size, compound vesicle on papule.	Good quality but only just beginning coalescing, vesicle on papule. Scab larger than on (A), and depressed.
Case 3.	Fine quality, large compound vesicle on papule.	Only fair quality and size, coalescing vesicle on papule. Scab larger than on (A).
Case 4.	Good quality and size, compound vesicle on papule.	Good quality and size, compound vesicle on papule. Scab larger than on (A).
Case 5.	Good quality and size, compound vesicle on papule.	Good quality and size, coalescing vesicle on papule. Scab dry and depressed.

We thus obtained: (A), five vesicles—three good, one fairly good, and one fine large; (B), four vesicles—one small beginning coalescing, one only fair coalescing, one good compound, one good coalescing, and one failure. The virus is evidently not so active in (B) cases as in (A) cases.

Experiment 5.—October 31, 1898. Virus No. 534, collected October 27, 1898.

Control, October 28 and 29, 1898: Five cases vaccinated in three spots each by needle scarification. Result, seven days after vaccination: All the cases "took," but only thirteen vesicles were obtained—six good, six fair, one poor. This was the original test of this virus and showed it to be distinctly below the standard in quality.

Experiment: Five children vaccinated in two spots each (A and B) as in Experiments 3 and 4, except that successively weaker solutions of KOH were used and that after the application of the acetic acid the surface was washed with water and then dried.

Appearance after denudation is noted under each case.

Results, seven days after vaccination:

	A (Needle Scarification).	B (KOH Denudation).
Case 1.	Good quality and size, compound vesicle on papule.	[KOH solution weaker than in Experiments 3 and 4. Surface after denudation same as in former experiments.] Small beginning vesico-pustule around edge of depressed eschar.
Case 2.	Good quality and size, compound vesicle on papule.	[KOH solution weaker than in Case 1 Surface after denudation a little more red around edges.] Good quality and size, compound vesicle on papule. Vesicle is even larger and better quality than in (A).
Case 3.	Good quality and size, compound vesicle on papule.	[KOH solution still weaker than in Case 2. Surface after denudation reddish, also more red in centre.] Rather poor quality, small single vesicle on papule.
Case 4.	Good quality, fair size, compound vesicle on papule.	[KOH solution same strength as in Case 3. Surface after denudation reddish.] Good quality, fair size, compound vesicle on papule.
Case 5.	Good quality and size, compound vesicle on papule.	[KOH solution same strength as in Cases 3 and 4 Surface after denudation bluish and parchment-like, as in experiments with stronger solutions.] Good quality and size, compound vesicle on papule, but not quite so good as (A).

We thus obtained: (A), five vesicles—four good quality and size, one good quality and fair size; (B), five vesicles—one small beginning, two good quality and size, one good quality and fair size, one rather small and poor quality.

Note, made at time of inspection of these cases: "In all this lot, the vesicles seven days after vaccination looked as they usually do six days after vaccination. The less vigorous denudation with a weaker solution of KOH seems to result in vesicles more like those of usual method of scarification with needle. The vesicles are of better quality, with smaller eschars and less depression than when the stronger solutions of KOH are used."

A study of the cases in detail, however, not only in this experiment but in those which preceded it, shows that in almost all the cases in which vaccination by the (A) and (B) methods have both been successful the (A) vesicles were of better quality and size than the (B) vesicles.

Summary of results of all the experiments:

	Number of Insertions	Character of Vesicles Obtained.					Percentage Successful.
		Good.	Fairly Good.	Fair.	Poor.	Total.	
KOH denudations:							
KOH alone	10	7 (70%)	0	0	1 (10%)	8	80.
KOH (on same arm with needle scarification).	12	3 (25%)	2 (16.67%)	1 (8 33%)	3 (25%)	9	75.
Totals............	22	10 (45.45%)	2 (9.1%)	1 (4.54%)	4 (18.18%)	17	77.27
Needle scarifications: (On same arm with KOH denudation).	12	8 (66.67%)	2 (16.67)	2 (16.66%)	0	12	100.

From these results it appears that vaccination performed by denudation with solutions of KOH is less likely to be successful than when performed by needle scarification. This fact the writer believes to be due to the formation of an eschar by the KOH which makes the surface denuded resemble parchment. This coagulation of the albuminous elements of the tissues closes the mouths of vessels and lymphatics, and renders the entrance of the vaccine organism and its absorption difficult. This action of KOH solutions upon the skin was studied, at the writer's request, by Dr. Anna L. Williams, one of the bacteriologists of the New York City health department. After application of the KOH to the skin upon the abdomen of a calf, sections of the skin through the denuded area were cut out and examined microscopically.

A summary of Dr. Williams' report is as follows:

"1. Epidermis completely destroyed, as also some parts of true skin.

"2. The lower parts of the hair bulbs remain; also lower parts of sweat and sebaceous glands.

"3. The remaining portion of the skin is covered with a layer of necrosed tissue, which takes a deep blue stain, and its structure is indistinguishable. This layer is about as thick as the epidermis and penetrates irregularly into the true skin.

"Conclusion: There may be an obstacle to the entrance of the vaccine organism either in the presence of the necrosed tissue or in the alkalinity of it."

The writer's conclusions as the result of these experiments are as follows: It is possible that a person of great skill and experience in the use of this method of KOH denudation would learn to apply the caustic potash in such a way as not to produce an eschar thick enough to prevent success; but the well-known local effect of KOH upon the skin makes it evident that some cauterization cannot be avoided, and that in so far as an eschar results the entrance of the vaccine organism will be interfered with.

The denudation method is slower than scarification, and if acetic acid is used to neutralize the KOH, the method is not less painful, as the acid causes a marked smarting effect. The use of the acid, however, might be omitted, as it did not appear in any of these experiments to diminish the tendency to the formation of an eschar.

Very active virus, such as is issued by the New York City health department, will give vesicles of too large size unless the scarified area be very small, not more than one-eighth of an inch square. It is difficult to denude so small an area with a liquid application.

The KOH method is naturally less terrifying to the child than the use of any sharp instrument. It is less painful if acetic acid is not used, and so far as the drawing of blood is concerned, it also has an advantage over scarification. It is, however, the opinion of the writer, and he believes this will be supported by the opinions of vaccinators of large experience, that no ordinary blood flow interferes with the "taking" of good virus thoroughly rubbed or scratched in. It is, of course, better for cosmetic reasons not to draw blood, and it must be admitted that it is difficult to avoid doing so by the usual methods of scarification, but it is a mistake to think that a little flow of blood will endanger the success of the vaccination.

To summarize these conclusions, then, the advantages of the KOH denudation are: (1) It is less painful and less terrifying; (2) it does not draw blood.

The disadvantages are: (1) It takes more time. (2) It requires more skill. (3) It is difficult by this method to denude an area small enough; the vesicles are likely to be too large if the virus is very active. (4) It is less certain than scarification, no matter how skilfully done, because of the formation of an eschar which interferes with absorption.

Finally, the writer believes that the disadvantages named, together with the fact that a rather elaborate equipment is required, make the KOH method impracticable for use in wholesale vaccinations such as are performed by public vaccinators. As to its value in private practice, if it be deemed important in any particular case, such as that of a very nervous child, to avoid terrifying him, or to spare him the slight pain caused by scarification, this method may very well be tried; but unless the physician is skilled in the use of the method, or unless the virus is so active that it will "take" no matter how it is applied, he must not be surprised if failure is the result.

The Diplobacillary Conjunctivitis of Morax.—Auguste Collomb found the diplobacillus in about three-fifths of the cases of conjunctivitis and blepharoconjunctivitis, whether acute, subacute, or chronic, which he examined, or from six to ten per cent. This was during several months when he was able to make complete and satisfactory examinations. Under other circumstances the cases represented about four per cent. of the patients examined.—*Revue Médicale de la Suisse Romande*, December 20, 1899.

The Semeiological Value of Laughter.—J. M. Raulier analyzes laughter as expressed in pathological and patho-psychiatric conditions and in psychoses.—*Archives Générales de Médecine*, December, 1899.

Eruptions Caused by Picric Acid.—H. Cathelineau gives a description of affections of nails and epidermis due to picric acid used in the arts or medicinally.—*Archives Générales de Médecine*, December, 1899.

Typhoid Fever and Pregnancy.—De Grandmaison reports a case in which the typhoid infection caused an abortion which then reacted upon the fever with a fatal result.—*Archives Générales de Médecine*, December, 1899.

Fatal Hemorrhage during the Course of Chronic Gastritis.—M. Péhu reports a case, and concludes that the hemorrhage of the exulceratio simplex is the result of a vascular lesion independent of small submucous abscesses; that the exulceratio simplex cannot be considered as the first stage of Cruveilhier's simple ulcer, for in the case reported the hemorrhage was apparently the result of a diffuse general gastritis, without ulcer, the process involving the blood-vessels. The patient was an alcoholic who had suffered for ten years from gastric symptoms resembling those of ulcer. —*Archives Générales de Médecine*, December, 1899.

Sensory Aphasia.—Dr. Touche performed autopsies upon nine patients who had suffered from sensory aphasia. In one case the affections interfering with speech were to be attributed to the interruption of communication between the various speech centres rather than to lesions of the centres themselves. In another the speech area was affected only in its inferior portion. In a third a slight subcortical softening near the second temporal convolution produced verbal deafness and jargon aphasia. Lesions of the second parietal and part of the ascending parietal existed in subjects who had apparently been cured of aphasia.—*Archives Générales de Médecine*, December, 1899.

Infectious Diseases.—Jules Renault has pursued a series of researches into the phenomena known as agglutination, or the effect produced upon certain bacteria by the action of immunizing serum. They are rendered immobile and gathered into little groups or agglomerations. This fact is of use in the serum diagnosis of typhoid fever; agglutination has been found in fourteen out of fifteen cases of Asiatic cholera, in the Malta fever of Mediterranean countries, in the latter weeks of Bombay pest, in infections due to the pneumococcus, and in glanders. It is not present in infections due to the coli bacillus, in tetanus, in diphtheria, nor in staphylococcus infections.—*Archives Générales de Médecine*, December, 1899.

Fracture of the Anterior Superior Spine of the Ilium by Muscular Contraction.—Jacques L. Reverdin reports the case of a young muscular Englishman, who slipped on his left running down an incline, just as the right leg was about to be carried forward. To avoid falling on his back, he instinctively bent the trunk over the left thigh. The flexors were strongly contracted, among them the sartorius and the tensor vaginæ femoris, which are attached to the iliac spine, and which pulled it so violently as to cause its fracture.—*Revue Médicale de la Suisse Romande*, December 20, 1899.

Massage is beneficial in ulcers, especially centripetal effleurage at the sides and below the ulcer in proportion to the induration of the edges.—HARTSCHEK.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

Publishers

WM. WOOD & CO., 51 Fifth Avenue

New York, January 27, 1900.

THE BACTERIOLOGY OF ENDOCARDITIS.

That endocarditis is of bacterial origin there is little room for doubt, but there is good reason to believe that the etiological factor is not always the same, various observers having found different micro-organisms. While often an associated, or secondary, phenomenon of other infectious diseases, the inflammation of the endocardium may take place as an independent, or primary, disorder, the infecting agents gaining entrance through any one of a number of portals, of which evidence has recently been adduced that the tonsils constitute one. The lesions and the symptoms vary widely in individual cases in accordance with the virulence and the pathogenicity of the micro-organisms concerned, and naturally also with the character of the primary disorder when the endocarditis is secondary.

To the cases of endocarditis already recorded in which bacteria were isolated, MacCallum and Hastings (*Journal of Experimental Medicine*, vol. iv., Nos. 5 and 6, p. 521) report an additional instance in which they found a hitherto undescribed micrococcus. The patient was a man, thirty-seven years old, who presented symptoms of acute endocarditis of the aortic and mitral valves, with infarctions in the spleen and the kidneys. From the blood during life, and from the valvular vegetations, the infarctions and other parts after death, there was demonstrated both microscopically and in pure culture, in large numbers, a small micrococcus, occurring mainly in pairs, sometimes in short chains, staining by Gram's method, growing in small, pale, grayish-white colonies on gelatin and agar, at first clouding bouillon, which then becomes clear with a whitish sediment, not producing gas in glucose media, liquefying gelatin slowly, and to some extent also blood serum, and characterized especially by its behavior in milk, which it acidifies, coagulates, and subsequently liquefies. It produces a milk-curdling ferment, and also a proteolytic ferment, each of which is separable from the bacterial cells. It remains viable for months in old cultures, and it is tolerably resistant to the action of heat and antiseptics. The micrococcus is pathogenic for mice and rabbits, causing either abscesses or general infection. Typical acute vegetative endocarditis was induced experimentally by intravenous inoculation of the organism in a rabbit and a dog, and the cocci were demonstrated in pure culture in the vegetations and other parts of these animals after death. Although the micrococcus described bears some resemblance to the pneumococcus and the streptococcus pyogenes on the one hand, and to the pyogenic staphylococcus on the other hand, it is readily distinguished from each of these species by the cultural features that have been described, and that are so obvious that the differentiation of these species from the micrococcus in question need not be discussed in detail. The organism is, therefore, considered to be a new species, and on account of its fermentative properties the name micrococcus zymogenes has been proposed.

THE CIGARETTE QUESTION.

Few physicians, probably, would recommend the use of the cigar, pipe, or cigarette as an aid to the preservation of good health or as a remedy for disease. Notwithstanding these adverse views, there are yet many medical men who think that the harm said to be effected by the use of tobacco has been somewhat exaggerated. There is, too, another point in connection with smoking concerning which opinions widely differ; that is, in regard to the particular form of the habit calculated to do most injury to the system. It would seem to have become, of late at any rate, in the minds of the general public almost an "article of faith" that for its deleterious effects the palm must be awarded to the cigarette. If one could believe the statements which often appear in certain of our lay journals, the cigarette is as insidious and as far-reaching in its death-dealing operations as is the bubonic plague. In sooth, the term "cigarette fiend" would seem to have taken its place as a permanent addition to our American vocabulary.

The cigarette has been stigmatized as poisonous in all its component parts. The assertion has been made times without number that the tobacco of which it is composed is adulterated with opium and an "unclassified alkaloid," and that the paper is poisoned with arsenic, copper, or chlorine. In 1888 *The Lancet* Analytical Sanitary Commission was appointed to probe into this matter, the result being that the cigarette left the court without a stain on its character, at least so far as the foregoing allegations against it were concerned. The same verdict was brought in for the cigarette under examination in this country. Notwithstanding this acquittal the minds of the American public were by no means set at rest on the point, and in 1891 a veritable crusade against the cigarette was inaugurated, which has been carried on more or less energetically up to the present day. Agitation to the same end has been proceeding, but to a lesser extent, in Great Britain. In consequence of this *The Lancet* procured four brands of cigarettes in New York and six in London, in the majority of instances the brands being the same, and subjected them to careful analysis in its laboratory. The report says that foreign toxic substances were not found in a single instance, and among those looked for, both in the paper wrapper and the tobacco, were morphine, phosphorus, arsenic, mercury, copper, and other heavy metals. The report sums up by declaring that "there is not a single factor in these numerous results upon which can be fairly based any allegation of the presence of a substance producing injury to health."

We hold no brief for the cigarette, and there is no intention on our part to uphold smoking in any form. Attention has been drawn in these columns on several occasions to the fact that cigarette smoking by the young cannot be practised with impunity. Before the age of sixteen years the use of tobacco should be absolutely tabooed. But to assert that cigarette smoking *per se* exerts a more pernicious influence on the health than the seductive cigar or the soothing pipe, is to put forth an argument for which there is no sufficient proof. Probably the following rules, if adhered to, would meet the requirements of most of the case: Don't smoke when young; don't inhale the smoke; and don't smoke to excess.

THE WHOLESALE DESTRUCTION OF FORESTS.

In newly settled countries which are thickly timbered it is a matter of prime necessity for the purposes of agriculture to clear the land. In many regions where population is sparse, timber felling as a means of livelihood is largely followed. This is of course as it should be, although even in such cases a wise discretion should be exercised. Unfortunately, however, the same course is followed in districts where the conditions are different. In Northwest Canada, for instance, there is as yet no fear that any great harm will be done by the lumber operations there carried on, as the virgin forests are so vast in extent that there is seldom necessity for re-logging before the trees have had time to arrive at maturity. But in parts of this country the situation as regards the forests differs greatly, and it is asserted authoritatively that, if the present system is proceeded with, the virgin forests of the South bid fair to be soon destroyed. The same authority, Dr. Schenck, is responsible for the statement that if the forests are lumbered out rapidly as at present, and if the fires are allowed to rage unchecked, the same condition will speedily prevail in the South that now prevails in the Lake States.

To prevent the occurrence of this deplorable consummation the committee on parks and forestry of the Asheville, N. C., board of trade has decided to appeal to the nation. This committee has issued a call for an interstate meeting to be held in Asheville, on November 22d, to form an association to further the project of a National Southern Park, and to induce Congress to appoint a commission to inquire into the feasibility of the project, to investigate its desirability, and to ascertain if it is practicable to secure such a park. It is to be hoped that the project may find favor with the "powers that be." Trees are not only to be desired from the standpoint of beauty, but also play a very important hygienic part in the scheme of the universe. In a treeless, hilly country floods are frequent and destructive. Trees are the chief factor in distributing and regulating the rainfall, and in dry seasons by their action in holding back evaporation preserve the water supply.

THE PLAGUE A MENACE TO BRITISH AND BOER TROOPS IN SOUTH AFRICA.

There have been cases reported of bubonic plague in and about the Transvaal during the past year. In February, 1899, a supposed case of plague was announced at a small town near Pretoria. Another case of a like nature occurred at another town nearer the Portuguese boundary, and it is now definitely known that the disease has broken out in the neighborhood of Delagoa Bay. This is perhaps the most serious news in connection with the campaign in South Africa that has yet been published. The consequences of the plague attacking the armies in the field are too awful to contemplate. But the possibility of such an occurrence must be taken into account. The conditions under which soldiers are compelled to live, and the inevitable lack of efficient sanitary arrangements in their camps, by which alone the disease can be stayed, present peculiarly favorable features for its spread. Cantlie, Simpson, and Manson have already uttered notes of warning on this point, and now Professor Sambon has emphasized these admonishments in an article contributed to the *British Journal of Tropical Medicine.* Sambon thoroughly agrees with Manson that the plague is not a water-borne but a rat-borne disease, and in addition draws attention to the fact that it can be conveyed by mice, squirrels, monkeys, dogs, cats, and man himself. He also gives as his opinion that fleas, bugs, and flies are likewise very important agents in the dissemination of plague, and that it is probably through fleas that the disease is most frequently conveyed from rat to rat, from rat to man, and from man to man. These are the principal measures recommended by Sambon to check the inroads of the plague: (*a*) The avoidance of importing grain and other food stuffs from infected places, as rats invariably accompany such cargoes. It is well known that grain ships have been a principal source of plague epidemics; (*b*) the destruction of rats in ships, especially when plague-infected or leaving plague-stricken localities; (*c*) the destruction of rats in towns exposed to infection; (*d*) the destruction of stray dogs and cats, which may become carriers of the disease when rats begin to die; (*e*) the destruction of fleas in houses and on pet animals; (*f*) the isolation of plague patients; (*g*) the disinfection of all that comes in contact with the latter.

The belief that rats were an important factor in spreading the plague was firmly held by the ancient Greeks, and Sambon relates that in Asia Minor, at the very door of the plague, they worshipped Apollo "*σμινθος*," "that is to say, Apollo the rat, whose arrows spread the plague, and at the same time as the destroyer of rats." This awful divinity was represented on monuments as treading on a rat. In Roman times, when Esculapius replaced the more ancient god of medicine, we again find the same fact recalled on a coin of Lucius Verus struck at Pergamum. It represents Esculapius with a rat at his feet, and a small naked figure standing by with arms outstretched. It is, however, not absolutely proven that the plague is disseminated by rats, although the evidence in support of the theory is remarkably strong—so strong indeed that the destruction of these vermin in infected regions and ships is a course that should, in all instances, be pursued.

With regard to the plague in Portuguese South Africa, there can be no doubt but that it constitutes a grave menace to both the armies in the field. In the first instance it will find an eminently congenial soil amid the filth of the Portuguese towns, and in the second place the transportation of provisions from Lorenzo Marques to the Transvaal will afford favorable facilities for its introduction to that country. In order to prevent so frightful a catastrophe, pressure should be brought to bear upon the Portuguese authorities to induce them to exercise the strictest supervision both over cargoes coming in by sea and over the food stuffs sent inland.

A DUBIOUS DISCOVERY.

The announcement made in several British lay journals, that Professor Metchnikoff of the Pasteur Institute has discovered the means of almost indefinitely prolonging life, will be received by the medical profession with feelings akin to disgust. The Paris correspondent of the London *Morning Post* reports the wonderful new theory in the following well-chosen words: "Professor Metchnikoff's experiments show that the explanation of senile atrophy hitherto obtaining is erroneous. The theory was that certain blood cells devoured others when the vital functions began to weaken. The organic poisons thrown off energetically in youth were believed to remain in the system in old age, or at least to be less energetically ejected, and to poison the finer cells while without action on those of the conjunctive tissues. The noble cells died and became the prey of the other or plebeian cells, thus bringing about the atrophy of the organ wherein the metamorphosis took place. This explanation is erroneous. Professor Metchnikoff has discovered and proved conclusively that the noble cells are not dead in organs atrophied by senility, and, moreover, that they may be multiplied. By assisting them in their struggle with the plebeian cells they will continue to live as actively as in youth. Theoretically, the organism will cease to grow old, and in practice life will be prolonged."

Serums of all kinds have been discovered in profusion in recent times, several of which have been altogether discredited, while others have failed to give the results claimed for them by their authors; but this is only the second occasion within the memory of the present generation that a prominent scientific man has publicly asserted that he had found out how to prolong life to practically an unlimited extent. The reputed discovery carries one's thoughts back to the Middle Ages, when many charlatans averred that they possessed the secret of the elixir of life. A discreet scepticism will assuredly be the attitude of mind of the medical profession with respect to Professor Metchnikoff's reported successful investigations. Probably, however, the public is being hoaxed in the matter, and the professor's name is being used without his knowledge. It is to be hoped that such may prove to be the case. Already too many scientific men of note have besmirched their reputations and the noble calling to which they belong by claiming for their discoveries wholly preposterous curative qualities.

THE TREATMENT OF TUBERCULOSIS WITH TUBERCULIN.

Although the furore that followed the announcement by Koch, in 1890, of a specific remedy for the treatment of tuberculosis soon subsided, in consequence of misguided zeal, unrealized anticipations, and disappointed hope, the distinguished bacteriologist who, at the time, appeared to be forced by his government into a premature publication, has persisted in his investigations along the same lines, and a number of the more conservative of those who adopted his suggestions still continue in the use of his products. It has been shown at least that tuberculin is capable of inducing local and general reaction in the presence of tuberculosis, and that by the systematic injection of gradually increasing doses it is possible to render the infected individual resistant to the toxic activity of the products of the tubercle bacillus. The former of these phenomena has been successfully applied in the early diagnosis of the disease, particularly in animals; and the latter in the treatment of the developed disease.

In a thoughtful address delivered recently before the tuberculosis commission of the Society of German Naturalists and Physicians, Petruschky (*Berliner klinische Wochenschrift*, 1899, Nos. 51 and 52), director of the Bacteriological Institute of the city of Dantzic, pointed out the impossibility of curing tuberculosis with a single brief course of treatment with even specific remedies, by reason of the nature of the anatomical lesions of the disease. Such cure must consist in the permanent suppression of the infectious agents and their toxins, and treatment, to be successful, must therefore be extended over long periods of time. Mere restoration to physical activity and earning capacity is not sufficient. Upon the basis of nine years' experience, Petruschky expresses the opinion that the desired result can be obtained with the aid of tuberculin, and he reports twenty-two cases in which cure in this sense was effected, the patients being freed of symptoms and not reacting to injections of tuberculin, and tubercle bacilli being absent from the sputum for periods of from six to twelve months. A graduated plan of treatment was pursued, the injections being discontinued with the cessation of the reaction to tuberculin, and being resumed at intervals of three or four months, when it was found that the reaction to tuberculin was again present.

News of the Week.

Typhoid Fever is prevailing to an unusual extent in Trenton, N. J. During last week there were forty cases and five deaths.

Dr. Conan Doyle, the author, has returned to medicine, according to the *Medical Press*, and will start soon for South Africa to take charge of a field ambulance.

The Prescription of Proprietary Remedies.—At a recent meeting of the Memphis (Tenn.) Medical Society a resolution was passed condemning the use of proprietary medicines.

"The Maryland Medical Journal" appears with the new year as a monthly instead of a weekly. The change is an improvement in a journal which has always held a high rank in American periodical literature.

Diphtheria in a Children's Home.—The Fairfield County (Conn.) Home for Destitute Children at Norwalk is under quarantine on account of two cases of diphtheria occurring there recently. There are also several cases of measles in the same institution.

A Death from Seasickness.—A four-year-old boy died on an Atlantic steamer just after it reached the pier in this city last Sunday, and the ship's physician attributed the death to exhaustion following seasickness, from which the child suffered severely during the entire voyage.

Carbolic Acid to be Dearer.—The price of carbolic acid has risen quite rapidly during the past week or two, owing to the impossibility of importing any from Great Britain. The scarcity there is said to be due to the fact that this substance is necessary in the manufacture of lyddite.

"A New Auto-Extension Fenestrum Splint" is the name given to a form of splint described at a meeting of the Tri-State Medical Society at Memphis. The apparatus is ingeniously constructed and will doubtless be serviceable in many cases, but what in the world is a fenestrum?

Smallpox is reported from many towns in North Carolina, and in some places prevails to such an extent that schools and churches have been closed and the holding of courts has been stopped. The disease has appeared also at Blackstone, Va., where the schools have been closed.

Medical Students Robbed.—One of the porters employed in the Bellevue Hospital Medical College was recently arraigned in the police court charged with having stolen clothing and other property from students, and was held for trial. There have been numerous complaints of theft of various articles in addition to overcoats and canes.

To Guard against Premature Burial.—The Society of Medical Jurisprudence recently presented a communication to the New York City board of health, calling attention to the manner in which death is now ascertained and certified to. In the communication it is asserted that the "distinction between real and apparent death, according to the scientific authorities who have paid special attention to this question, being a delicate task and requiring precise scientific tests—first of all, only authorized practitioners of medicine should decide whether a person is dead or not. As it is now, any person without any medical knowledge or trained capacity of observation who happens to be present when a person stops breathing can report him to be dead, and in most cases the physician who has seen him alive will certify to his death without even having seen his body, much less having tested the reality of actual death. We therefore respectfully suggest a change in the blank forms of death certificates so that they be made to contain the declaration that the physician personally has examined the body. We furthermore recommend that the chief signs of death be enumerated in the blank, and that the physician shall indicate the presence or absence of each with 'Yes' or 'No.' The questions which we would suggest to ask would be: Has the respiration stopped permanently? Has the pulsation of the heart stopped permanently? Do the dependent portions of the body show a purple discoloration? Is rigor mortis present? Are the corneas dull? Are the pupils dilated? Are there unmistakable signs of putrefaction? Furthermore, we suggest that by ordinance your honorable board make it illegal to do anything to the body of the supposed dead which, if he were alive, would cause him pain or injure him, before the certificate of his death has been signed by the physician."

Professional Men in Cuba.—An Havana newspaper says that the number of doctors and lawyers in the island is out of proportion, both as regards the number of inhabitants and the money in Cuba. Nevertheless, a great many students in both professions will soon be qualified, and many Americans are practising medicine illegally on the island. Owing to the lack of other occupations for young Cubans under the Spanish régime, those who could not afford to go abroad to study engineering or other professions were forced to become lawyers or doctors, these being the only degrees that could be obtained in the island.

Military Hospitals for South Africa.—We learn from the *British Medical Journal* that Lord Iveagh has offered to provide at his own cost a completely equipped hospital for the lines of communication in South Africa. The hospital will be known as the "Irish Hospital," and the chief surgeon will be Sir William Thomson, lately president of the Royal College of Surgeons in Ireland. The staff will consist of four surgeons and six dressers. The offer of Mr. Langman to equip a station hospital of one hundred beds for the lines of communication has also been accepted by the War Office, and Mr. Robert O'Callaghan, surgeon to the French Hospital in London, will be the senior surgeon.

The California Crusade against Consumptives.—The board of health of Oakland, Cal., has advised the board of education of that city to dismiss from the public schools any teacher or pupil suffering from pulmonary tuberculosis and to prevent the admission of any such sufferer in the future. One of the proposed regulations provides for a compulsory bacteriological examination of any pupil or teacher under pain of dismissal.

Typhoid Fever is still very prevalent at Ladysmith, twenty deaths having occurred there in two days.

A Congress for the Study of Tuberculosis will be held in Naples in the spring of the present year, in connection with an exposition of hygiene.

Accidental Poisoning of a Physician.—Dr. William J. Belcher, an English physician, died a short time ago in consequence of his having accidentally swallowed carbolic acid by mistake for solution of magnesia, when mixing a draught for his own use.

A Gift to the Flower Hospital.—The widow and the daughter of the late Roswell P. Flower have given $200,000 to the hospital founded by him, the only condition attached to the gift being that the name "Flower Hospital" shall be retained in perpetuity.

The New York State Anti-Vivisection Society held its annual meeting at Saugerties last week. Officers were elected for the year as follows: *President*, Dr. John Vedder; *First Vice-President*, Mr. Renssalaer Potts; *Second Vice President*, Dr. Luigi Galvani Doane; *Secretary*, Anna Sargent Turner; *Treasurer*, Grace F. Reed.

An Indictment against a Christian Healer.—The grand jury in Council Bluffs, Iowa, has returned two indictments against a Christian Science healer and a woman for compassing the death of the daughter of the latter. The girl is reported to have died of appendicitis while the "healer" was praying over her, the mother having refused to have medical advice for the child.

A Question of Diagnosis.—There is a dispute between the Indiana board of health and the physicians in the western part of the State over the differential diagnosis of smallpox and chickenpox. The board of health officials assert that a smallpox epidemic prevails at Clay City and other places, but many of the physicians say the disease is chickenpox and point to the fact that there has not been a death, and also that vaccinated persons as well as those not vaccinated have had the disease. The disease, whatever it is, is increasing, and many persons are seeking vaccination. The presidents of the State Normal School and the State University have advised all the students to be vaccinated, and over one thousand have submitted to the operation. The State board of health announces that the disease prevails in fourteen counties in Indiana.

No Use for Bent Needles.—A new student in the training-school was detailed a few days ago to help in the out-patient department of one of the city hospitals. After a man had had a scalp wound sewed up the neophyte was asked by the dispensary surgeon to wash the needles. There were two dozen of them. Two or three were straight, the rest curved in various shapes. She washed the straight ones and threw the rest away. When remonstrated with for the waste, she was greatly astonished to hear that surgeons prized such things as bent and twisted needles.

"The Archives of Pediatrics."—Dr. Walter Lester Carr, of New York, will take editorial charge of this journal with the new year. Dr. Carr has been a frequent contributor to the literature of pediatrics, and his assumption of the editorship promises a better future for the *Archives*.

The Plague is reported to have made its appearance at Noumea, capital of the French penal colony of New Caledonia. Ten Kanakas have succumbed to the disorder and four whites have been attacked. The disease is said to be spreading.

A Prolific Descendant of Distinguished Ancestry.—There died on January 9th, at Philadelphia, a man aged fifty years, who was a descendant of Benjamin Franklin. His father was an officer in the war of 1812, and he was himself the father of twenty-one children.

Relief Work in Puerto Rico.—A report of the relief work for October and November in the island of Puerto Rico has just been published. The population of the island is estimated at 918,926. The average daily indigent during the two months was 221,087 persons; the average weekly sick 17,372, and the average weekly deaths 632 persons. The annual death rate was 35 per 1,000 inhabitants, while the normal rate of deaths is 26 per 1,000 inhabitants. The increased mortality was confined to the mountain districts, where, in some localities, the death rate increased three hundred per cent. The amount received for the relief of the suffering people of the island up to November 30th was $15,224. The amount disbursed up to the date mentioned was $7,417. Up to November 30th the total amount of food received to relieve the sufferers was 17,162,788 pounds. Of this 16,548,316 pounds has been issued up to November 30th. The amount of unissued food on hand at San Juan November 30th was 614,272 pounds. It is estimated that not less than 2,000 additional tons of food will be required before the end of January, when the plantains and bananas will be ripe. Four-sevenths of this amount should be of rice; two-sevenths should be of beans, and the remainder of the amount required should be either codfish or bacon. With the food already issued and now on hand, and with the 2,000 tons required in addition to that already issued, the total issue will be 20,162,788 pounds.

College of Physicians of Philadelphia.—At a stated meeting of the section on general medicine held on January 8th, Dr. F. Savary Pearce and Dr. J. M. Swan read a paper entitled "Friedreich's Ataxia, with the Report of a Fatal Case." The patient was a girl, seventeen years old, in whom the symptoms were first noticed at the age of three years. The knee-jerks were present for a long time, but were lost in the last years of life. Nystagmus also appeared late. The patient died of pulmonary tuberculosis, probably acquired from a brother, who died of the same disease. An autopsy could not be secured. Dr. Herman B. Allyn presented a communication entitled "A Case of Rheumatic Pericarditis, with Sero-Fibrinous Exudate; Recovery." The case was characterized by moderate elevation of the temperature, violent delirium, a duration of five weeks, and the occurrence of pleurisy as a complication. Dr. Hobart A. Hare read a paper entitled "A Case of Aortic Aneurism, in which Electrolysis was Performed Three Times." The operation consisted in the introduction into the aneurismal sac, through a hollow needle, of about ten feet of coiled gold wire, and the passage for about an hour of an electric current gradually increased from 2 to 100 milliampères. For a time injections of gelatin also were employed, a mixture of gelatin gr. xviii., sodium chloride gr. xviii., and water fl. ℥ ii. being used, and some seventy injections being made. Although fatal rupture eventually ensued, the patient's life was prolonged for some eight months. In another case similar palliation was effected. Dr. D. D. Stewart also reported a case of aneurism of the aorta, in which coils of wire were introduced on three occasions, and an electric current was passed, resulting in the preservation of life for a number of months. The specimen from this case was exhibited, and disclosed a fusiform aneurism of the ascending portion of the arch of the aorta, with an added saccular dilatation, in which the coils of wire were found surrounded by clot. Dr. Alfred Stengel presented a communication entitled "The Definition and Significance of Accentuation of the Second Pulmonary Sound." It was pointed out that the character of this sound depends essentially upon the relation between the pressure in the ventricle and that in the artery, and that the term accentuation is employed with relation to the first sound and to the other sounds rather than as an absolute qualification. The sound may undergo alteration in intensity, in pitch, and in quality. Dr. H. A. Hare was elected chairman and Dr. S. M. Hamill clerk for the ensuing year.

German Hospital, Philadelphia.—According to the annual report of the German Hospital, 2,890 patients were admitted during the year 1899 to the wards, while 37,071 visits were made to the dispensaries. In the Mary J. Drexel Home 382 patients were admitted during the year, and 5,797 visits were made to the dispensary. Reference was made to the increase of abuses in the dispensaries, and the insolence and arrogance of some of the applicants, who labor under the delusion that the city authorities furnish the means for the support of the free dispensaries.

A Great Question Tentatively Settled.—A committee appointed at the Northfield Summer Conference of Christian Workers, last August, to investigate the statements of Professor Atwater of Wesleyan University on the nutritive value of alcohol, has made an exhaustive report in a sixteen-page pamphlet. The committee acted in co-operation with the Non-Partisan National Women's Christian Temperance Union, the permanent committee on temperance of the general conference of the Methodist Episcopal Church, the Presbyterian Woman's Temperance Association, and a number of other scientific bodies, and has decided that alcohol is not a food.

Dr. V. Czerny, professor of clinical surgery at the University of Heidelberg, has accepted the invitation of Dr. Robert F. Weir, president of the American Surgical Association, to be present at the meeting of the association in Washington in May. He will read a paper on the "Surgical Treatment of Gall Stones."

Bequests to Charities.—By the terms of the will of the late Dorman B. Eaton several large bequests are made for educational and charitable purposes. Columbia and Harvard universities receive $100,000 each. The New York Skin and Cancer Hospital gets $10,000 and the Society for the Suppression of Vice $25,000.

The Fifth District Branch of the New York State Medical Association.—The sixteenth annual meeting of this branch will be held in Brooklyn on Tuesday, May 22, 1900. It is proposed to choose diabetes as the topic for discussion. Fellows who are particularly interested in this topic, and have any clinical data to present or theories to offer, are requested to correspond with Dr. J. C. Bierwirth, president, or Dr. E. H. Squibb, secretary, P. O. box 760, Brooklyn, N. Y.

A New Hospital for Boston.—By the will of the late Robert Breck Brigham, of Boston, the bulk of an estate estimated at $5,000,000 is given to charity. Provision is made for the establishment of a new hospital in Boston, to be known as the Robert B. Brigham Hospital for Incurables. The new hospital is to be maintained as "an institution for the care and support and medical and surgical treatment of those citizens of Boston who are without the necessary means of support and who are incapable of obtaining a living by reason of chronic and incurable disease or permanent physical disabilities." Nearly every charitable institution in the city is remembered, the most of them by $1,000 annuities. Some of them received larger bequests outright.

The Fourth International Congress of Psychologists will be held in Paris, August 20–25, 1900. The fee for members is 20 francs, which is to be sent to Dr. Pierre Janet, 21 Rue Barbet-de-Jouy, Paris. The work of the congress will be divided among seven sections, as follows: 1, Relation of psychology to anatomy and physiology; 2, relation of psychology to philosophy; 3, experimental psychology and psychophysics; 4, pathological psychology and psychiatrics; 5, the psychology of hypnotism and suggestion and related questions; 6, social and criminal psychology; 7, animal psychology, comparative psychology, anthropology, and ethnology.

The Consolidation of Medical Missions.—The International Order of the Double Cross was organized recently in this city. One of the primary objects of the order is the uniting of all medical missions and missionaries throughout the world. The membership is open to physicians, medical students, and nurses of both sexes, the active membership to be divided into four guilds—physicians, students, nurses, and helpers—and all medical missionaries are to be considered as honorary members. The emblem of the order, from which it gets its name, consists of the double cross formed by the crosses of St. George and St. Andrew. The following officers have been elected: *President*, Dr. G. D. Dowkontt; *Secretary*, Cyril H. Haas; *Treasurer*, the Rev. W. W. Smith, M.D.; *Registrar*, the Rev. Theodore F. Hahn. These four officials, together with Drs. William Steward, John B. Busteel, and H. Zeckhausen, form the executive council.

The Population of Cuba.—According to the returns thus far received from the 1,550 census enumerators in Cuba, whose work is nearly completed, it is estimated that the population of the island is about 1,200,000, or 400,000 less than the Spanish census of 1887 showed.

The Study of Tropical Diseases in Germany.—In the budget of the German empire for 1900 there appears a subsidy for the Institute of Tropical Hygiene which it is proposed to establish in Hamburg. The empire will contribute 20,500 marks yearly to the maintenance of the Institute, which is to be opened in October of the present year.

For the Restriction of Tuberculosis.—A joint meeting of the Philadelphia County Medical Society and the Pennsylvania Society for the Prevention of Tuberculosis was held on January 10th, and a series of papers dealing with the various phases of the prevention and the treatment of tuberculosis were presented. Dr. L. F. Flick read a paper dealing with the "Plans of the Pennsylvania Society for the Prevention of Tuberculosis." These include the education of the public by means of tracts describing the nature of the disease, its mode of spread, and the measures necessary to prevent its dissemination; and the erection of hospitals and sanatoria for the treatment of the disease throughout its various stages, particularly in the poor. At present the society, having no hospital of its own, is compelled to pay for the care of a number of patients in the few hospitals that will receive cases of the kind. Dr. J. C. Wilson read a paper entitled "The Necessity of Hospital Care of the Consumptive Poor." Hon. W. N. Ashman presented a communication entitled, "Work at Present Being Done through Private Charity in the Treatment of Consumption," in which he described the good accomplished particularly by the Rush Hospital for Consumptives. Dr. Howard S. Anders read a paper on "The Necessity for State Aid in the Treatment of Consumption among the Poor," in which he pointed out the duty of the commonwealth to its dependent sick. Rev. Charles Dickey discussed "The Cost of Maintenance and Management of Hospitals and Sanatoria for the Treatment of Consumption," contending that for the present it would be wisest to utilize existing resources by the isolation of special wards or the setting apart of special buildings for the tuberculous, instead of erecting costly plants and perhaps antagonizing the community rather than inviting its co-operation. Dr. Guy Hinsdale read a paper entitled, "Localities Suitable for the Treatment of Consumption in Sanatoria throughout Pennsylvania," showing that at least several parts of the State are admirably adapted for the location of such institutions by reason of their elevation and their climatic conditions. Dr. E. O. Otis, of Boston, read a paper entitled "The Necessity for City Hospitals for the Treatment of Advanced Cases of Consumption among the Poor," and he laid particular emphasis upon the necessity for the registration of cases in order to reduce to a minimum the liability of infection through otherwise undiscoverable foci of disease. Dr. J. M. Da Costa pointed out that by reason of the knowledge of the transmissibility of tuberculosis, as the result of scientific investigation, the general hospitals had been closed to tuberculous subjects, so that the necessity for providing for their special hospital care was particularly urgent and devolved upon the State. Other speakers were Major William H. Lambert, formerly president of the bureau of charities and correction, Dr. J. E. Stubbert, of the Loomis Sanatorium, and Mr. William B. Hackenburg, president of the Jewish Hospital.

Philadelphia Pediatric Society.—At a stated meeting held January 9th, Dr. S. M. Hamill exhibited a case of pulmonary obstruction in a girl about twelve years old, in which there had previously been attacks of tonsillitis and of measles, with a systolic murmur, most audible in the second left intercostal space adjacent to the sternum. The lesion was thought possibly to be a congenital one, although there was an absence of cyanosis and of clubbing of the finger-ends. The possibility of associated persistence of the ductus arteriosus was also considered. Dr. J. P. Crozer Griffith read a paper entitled "Miliary Scarlet Fever, with a Report of Cases." The opinion was expressed that the occurrence of a miliary eruption in cases of scarlet fever is unrelated to the severity of the primary disease and to the intensity of the cutaneous eruption. Dr. Alfred Stengel was elected president, Dr. Alfred Hand, Jr., secretary, and Dr. Herbert B. Carpenter treasurer, for the ensuing year.

Philadelphia Hospital. Dr. H. Augustus Wilson, clinical professor of orthopedic surgery in Jefferson Medical College, has been elected orthopedic surgeon to the Philadelphia Hospital, a newly created position.

New Medical Fraternity.—The Jefferson Society of Jefferson Medical College was installed as the Epsilon chapter of Alpha Kappa Delta Fraternity on January 6th.

The Pathological Society of Philadelphia.—At a stated meeting held January 11th, Dr. E. A. Woldert read a paper upon "Some New Stains for the Sporozoa of Malaria, with Specimens." Drs. F. A. Packard and A. Hand, Jr., exhibited specimens from a case of status lymphaticus, with gastric tetany. The patient was a child, three years old, with excessive secretion of glairy mucus and pronounced symptoms of tetany. Death occurred suddenly, without apparent cause, and post-mortem examination disclosed an enlarged thymus gland and unusual development of the lymphatic glandular apparatus of the small intestine, particularly the lower portion of the ileum. Dr. Joseph Sailer exhibited a specimen of syphilis of the spinal cord, presenting thrombosis in the floor of the fourth ventricle. The patient had received numerous arrow-wounds in South America, and it was thought that the instruments used might have been infected with syphilis through the saliva of the natives. Dr. Sailer exhibited also two specimens of mitral obstruction, one presenting the classical funnel-shaped appearance, and attended with a large excavated thrombus in the left auricle; the other showed apparent atrophy of the right ventricle, and the remains of multiple infarction of the spleen and of the kidneys. He exhibited besides the heart from a degenerate, whose death had resulted from a fall in consequence of acute intoxication with a small amount of alcohol. The aortic valve was constituted of only two cusps. Dr. Simon Flexner presented a human lung, showing actinomycosis. The lungs were indurated, and exhibited the characteristic sulphur-yellow granules. Dr. S. M. Hamill exhibited a specimen of hemorrhage into the suprarenal capsule and the connective-tissue capsule of the kidney, from an infant, seventy-eight hours old, born without complication. Dr. F. A. Packard exhibited caseous tuberculous adrenal glands from a man in whose case a diagnosis of Addison's disease had been made during life. The semilunar ganglia of the sympathetic also appeared thickened and altered. Dr. Alfred Hand, Jr., exhibited specimens of tuberculosis of the lung, spleen, and kidney, from a colored child. The lung was extensively tuberculous, and the remaining organs were the seat of miliary tubercles.

The Medical Service at the Paris Exposition has been organized by Dr. Gilles de la Tourette, formerly chief of clinic at the Salpétrière under Charcot. He has ten assistants, Drs. Donbre, Reymond, Critzmann, Bourges, Emory, Goubert, Laborde, Dandieu, Deschamps, and Gaillard.

Regulation of Ritual Circumcision.—The Hungarian government has issued a decree regarding ritual circumcision, placing the operation under medical supervision, and insuring that it shall be performed under the rules of surgical antisepsis.

Sanitary Progress in Guam.—In a recent report by Captain Leary, governor of Guam, it is stated that all precautions are being taken to improve the sanitary condition of the station as far as present means and facilities permit, but a suitable water-supply system is necessary in order that the ground cisterns and wells may be closed and sealed, as they are contaminated by absorption of drainage impurities. The evaporating-plant at the station is nearing completion, and the sewage system from the government houses to the ocean will be finished in a short time. Dr. Philip Leech, surgeon United States navy, in his report says that Assistant Surgeon Stone has persuaded the people of Agat to establish a hospital with ten beds. So striking have been the results that the authorities of the village are now building and have nearly finished an additional hospital for twenty beds. The people appear to be grateful for what is being gratuitously done for them, and seem to appreciate the importance of co-operating with the American physicians, not only in their medical work, as shown by their building hospitals at Agat, but also in their efforts to make sanitary improvements.

Philadelphia County Medical Society.—At the stated business meeting held January 17th, new members, delegates to the convention for revision of the Pharmacopœia, to the American Medical Association, and to the Medical Society of the State of Pennsylvania, and officers for the ensuing year, were elected, and the reports of the directors, the treasurer, the censors, and the publication committee were read. Dr. B. F. Stahl, chairman of the committee appointed to secure the admission of medical students to the Municipal Hospital for instruction in the diseases treated there, namely, diphtheria, scarlet fever, and smallpox, made a report stating that with the co-operation of the board of health and the physician-in-chief to the hospital, Dr. William M. Welch, courses of instruction had been instituted to classes of ten students each from the various medical schools in the city. The following officers were elected for the ensuing year: *President*, Dr. John Musser; *First Vice-President*, Dr. George Erety Shoemaker; *Second Vice-President*, Dr. Francis M. Perkins; *Secretary*, Dr. Ellwood R. Kirby; *Assistant Secretary*, Dr. William S. Wray; *Treasurer*, Dr. Collier L. Bower; *Censor*, Dr. Thomas H. Fenton.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending January 20, 1900. January 12th (changes by cable from Asiatic station).—Assistant Surgeon D. L. Wright detached from the *Monterey* and ordered to the *Isla du Luzon;* Medical Director D. Dickinson ordered to duty as a member of the naval medical examining-board, Washington navy yard, January 20th; Medical Director G. S. Beardsley detached from the naval retiring-board, Washington navy yard, and ordered home to wait orders; Medical Inspector J. C. Wise detached from the naval medical examining-board, Washington navy yard, January 20th, and ordered to duty as member of the retiring-board same day. January 16th.—Surgeon L. G. Heneberger detached from the naval recruiting rendezvous, Detroit, Mich., and ordered to the training-station, Newport, R. I.; Surgeon O. Diehl detached from the *Michigan* and ordered to the naval recruiting rendezvous, Philadelphia, Pa.; Passed Assistant Surgeon A. R. Alfred detached from the New York navy yard and ordered to the *Texas;* Passed Assistant Surgeon F. W. Olcott detached from the *Texas* and ordered to the naval recruiting rendezvous, Detroit, Mich.; Passed Assistant Surgeon H. D. Wilson ordered to duty on the *Michigan;* Passed Assistant Surgeon C. E. Riggs detached from the naval recruiting rendezvous, New York, and ordered to the New York navy yard; Surgeon H. N. T. Harris ordered to temporary duty on the *Vermont* in connection with the crew of the *Albany;* Assistant Surgeon R. Spear detached from the naval recruiting rendezvous, Philadelphia, Pa., and ordered to the *Constellation* temporarily; Assistant Surgeon H. A. Dunn ordered to the naval proving grounds, Indian Head, Md. January 18th (changes by cable from Asiatic station).—Passed Assistant Surgeon L. Morris detached from the *Helena* and ordered to the *Brooklyn;* Assistant Surgeon D. H. Morgan detached from the *Iris* and ordered home; Medical Director G. S. Beardsley placed on the list of retired officers of the navy from January 22, 1900; Medical Director J. M. Flint placed on the list of retired officers of the navy from February 7, 1900; Pharmacist J. H. McGuigan detached from the naval proving-grounds, Indian Head, Md., and ordered to the New York navy yard; Pharmacist S. Englander detached from the New York navy yard and ordered to the naval hospital, New York.

Heart Injury Without Immediate Death.—The case of a man at Brunswick, Md., is reported in which life persisted for sixty hours after the reception of several gunshot wounds, one of which, it was found on post-mortem examination, had perforated the heart and another the intestines.

Pennsylvania Board of Medical Examiners.—Dr. Henry Beates, of Philadelphia, a member also of the State Medical Council, has been reappointed a member of the Pennsylvania medical examining-board; and Dr. Hiram S. McConnell, of New Brighton, and Dr. R. W. Ramsey, of Chambersburg, were appointed members of the same board in succession to Dr. Joseph K. Weaver, of Norristown, and Dr. Samuel W. Latta, of Philadelphia.

The Burlington County (N. J.) Medical Society, at its annual meeting held at Mount Holly on January 16th, elected the following officers for the ensuing year: *President*, Dr. Frances S. Janney; *Vice-President*, Dr. W. P. Melcher; *Secretary*, Dr. A. W. Taylor; *Treasurer*, Dr. Enoch Hollingshead; *Censor*, Dr. J. W. Hollingshead; *Chairman of Medical Section*, Dr. V. H. Shipps; *Chairman of Surgical Section*, Dr. A. Small; *Diseases of Women and Children*, Dr. Emma Weeks.

The Montgomery County (Pa.) Medical Society, at its annual meeting held at Norristown on January 18th, elected the following officers for the ensuing year: *President*, Dr. J. J. Kane, Norristown; *Vice-Presidents*, Drs. D. W. Shelley, Ambler, and P. H. Corson, Plymouth; *Recording Secretary*, Dr. H. H. Whitcomb, Norristown; *Corresponding Secretary*, Dr. J. K. Weaver, Norristown; *Treasurer*, Dr. S. N. Wiley, Norristown.

Dr. Howard Kelly, of Baltimore, while lecturing at the Johns Hopkins University a few days ago, was bitten on the finger by a rattlesnake. He sucked the wound for a minute and then continued his lecture none the worse for his accident. The reptile had probably exhausted its supply of venom in striking at various inanimate objects before getting a bite of human flesh.

The Late Dr. W. A. Hammond.—The board of directors of the New York Post-Graduate Medical School and Hospital record with profound sorrow the death of their former colleague, William A. Hammond, M.D., surgeon-general of the United States army, retired. On the 4th of April, 1882, Dr. Hammond, who was then professor of diseases of the mind and nervous system in the University Medical College of this city, assisted in the organization of the faculty for the Post-Graduate Medical School. He was professor in the college from the date of its opening, October 1, 1882, at 209 East Twenty-third Street, until 1888, when he resigned his position and removed to Washington, D. C., where he suddenly died on January 5, 1900. Dr. Hammond was an accomplished executive officer, punctual, scientific, and thorough in his work as a clinician, and he always attracted large classes by the force and clearness of his teaching. It was, perhaps, owing to his effort more than to any other member of the faculty who resigned from the University of the City of New York, that the initial step was taken which led to the organization of the Post-Graduate Medical School. During the early years of its struggle for existence, Dr. Hammond gave most unsparingly of his talents, his time, and his pecuniary resources, toward its successful establishment, which he saw achieved during his term as professor.

He was most genial and courteous in his relations with his fellows. His memory will always be cherished by them with hearty appreciation of his great qualities.

The directors order this record to be spread upon their minutes, and a copy thereof sent to the surviving members of his family.

D. B. St. John Roosa, President; Andrew H. Smith, Vice-President; George N. Miller, Secretary.

Obituary Notes.—Dr. A. L. Boughner died at Chester, Pa., on January 16th, at the age of forty-four years, from septicæmia, due to a wound of the finger received three months ago. He was graduated from the Normal University, at Lebanon, Ohio, in 1882, and from the University Republique, at Ann Arbor, Mich., in 1885.

Dr. Thomas H. Franklin died suddenly on January 9th, at Atlantic City, at the age of fifty-nine years. He was a graduate of the medical department of the University of Pennsylvania, and he served in the Pennsylvania Cavalry during the Civil War.

Dr. S. P. Bartleson died suddenly at Clifton, Pa., on January 16th, in the sixty-ninth year of his age, apparently as a result of angina pectoris. He was a graduate of Jefferson Medical College.

Dr. Abraham H. Witmer, first assistant physician to the Government Hospital for the Insane in Washington, died on January 18th of cardiac disease. He was born in Lancaster County, Pa., fifty-four years ago, and was graduated from the Jefferson Medical College in 1866. He became connected with the hospital in 1876.

Dr. Lyman Rodgers, of Bennington, Vt., died suddenly on January 22d. He was a graduate of the medical department of the University of Vermont in the class of 1858. He was an ex-president of the Vermont State Medical Society, and had served a term as State Senator.

Dr. Alfred J. Watts died at his home in Brooklyn, N. Y., on January 22d, of apoplexy. He was born in England in 1825 and studied medicine there, obtaining his qualification shortly before coming to this country in 1848. He practised first in Utica and later removed to Brooklyn. He was the inventor of crystal or "fern-leaf" gold used in filling teeth, and he soon gave up practice and devoted his time to the perfection of his invention.

Dr. John Cargill Shaw died on January 23d, from pneumonia, at his home in Brooklyn, in his fifty-fourth year. He was born in Jamaica, W. I., and came to this country in his seventeenth year. He was a graduate of the College of Physicians and Surgeons in this city in the class of 1874. For several years he was attached to the medical staff of the Long Island College Hospital and of St. Mary's Hospital, and he also served for four years as superintendent of the Flatbush Asylum.

Dr. Columbus W. Krise, of Carlisle, Pa., died suddenly on January 23d, at the age of fifty-two years. He was born in Gettysburg, and was graduated from the medical department of the University of Maryland in 1871. He was a member of the Cumberland County and Pennsylvania medical societies and the American Medical Association.

Progress of Medical Science.

New York Medical Journal, January 20, 1900.

Chronic Abscess of the Frontal, Ethmoidal, and Sphenoidal Sinuses followed by Meningitis and Death.—J. H. Bryan records a case of this nature which upon operation showed thick pus and granulation tissue in the frontal sinus, with caries of its front wall and of the entire ethmoid bone. All dead bone which could be detected was removed. On the sixth day after operation, the temperature began to rise and sepsis developed. In spite of prompt intervention, including the use of anti-streptococcus serum, death resulted two days later. Autopsy revealed acute leptomeningitis secondary apparently to ethmoid caries. Sphenoid disease undiscovered at operation was also present.

The Therapeutics of Heroin.—M. Manges concludes an elaborate article upon this new remedy. Replies to a circular letter show success in three hundred and eighteen and failure in ninety-eight cases of various affections, principally of the air tract. A valuable bibliography is appended.

The Influence of School Life on Vision.—P. A. Callan has examined many school children during the last twenty-five years. He thinks that they are overcrowded in their studies, and that this has much to do with the large number of visual defects met with in this class of patients.

Cholelithiasis.—E. C. Davison gives a general description of this affection. He reports one personal operative case, and compares the advantages and relative indications for cholecystectomy and kindred operations.

Diarrhœa.—C. O. Molz enumerates the general causes, varieties, characteristics, and therapeutic measures of the various forms of diarrhœa. He follows the teachings of William Osler and L. E. Holt.

Enucleations of the Eye.—D. Webster reports cases of enucleation for panophthalmitis, for degenerated cataract with secondary hemorrhagic glaucoma, and for ophthalmitis, the result of injury.

On the Detection of Calculi in the Liver and Gall Bladder.—By Carl Beck. See Medical Record, vol. lvi., p. 642.

Suppurative Ethmoiditis and Its Treatment.—By F. S. Milbury. See Medical Record, vol. lvi., p. 684.

Medical News, January 20, 1900.

Gonorrhœa; Its Dangers to Society.—Albert Neisser, in discussing this subject, states that one feature of gonorrhœa of special significance is the fact that its infectiousness may persist for a very long time in spite of seemingly successful treatment of the local affection of the genitalia. The affection does not remain limited to the primary focus of infection in the mucous membrane, but progressively invades other parts: neither does it limit itself to the superficial mucous membrane. Special mention is made of gonorrheal arthritis with its tendency to relapses, ankylosis, and disability. At least ten to twenty per cent. of all blindness is due to gonorrheal infection. Another important factor to be noted in this disease is the sterility which results from it. Neisser concludes that we now know that this disease is always infectious, communicated from one person to another, and we can take measures to prevent its spread.

Diuretics in Renal Dropsy: Their Indications and Uses.—E. R. Axtell divides diuretics into two classes, the direct and the indirect. For practical purposes he further divides the direct diuretics into two classes, the saline and the stimulant diuretics. Axtell believes that much harm can result from the use of these drugs unless they are judiciously chosen, and he contends that all diuretics should be withheld in acute nephritis until the acute inflammation has subsided. Renal diuretics should be used in those cases of dropsy in which there is great need of a drug that will make the remaining kidney tissue do its work actively—but not then, until diaphoretics and hydragogue cathartics have been tried. A brief consideration of each of the following drugs concludes the paper: scoparius, squill, caffeine, pilocarpine, digitalis, diuretin, sweet spirits of nitre, and calomel.

A Visit to the Newest Psychopathic Hospital.—Frederick Peterson describes the psychopathic hospital at Giessen—about an hour from Frankfort-on-Main.

The Operative Treatment of Myopia of High Degree by the Removal of the Crystalline Lens.—By Charles Stedman Bull. See Medical Record, vol. lvi., p. 636.

Boston Medical and Surgical Journal, January 18, 1900.

Otitis Media in All Grave Diseases of Infancy.—E. H. Pomeroy calls attention to Ponfick's table of autopsies performed upon one hundred children who had died of various diseases, as heart disease, gastroenteritis, burns, pneumonia, etc., in only nine of which the ears were found to be normal. He believes that most of the diseases of infancy are more positively and demonstrably infectious from bacteria than we can easily prove in adults, and considers the middle ear as an incubator and generator promoting general toxic disturbance in many cases of localized infectious diseases. He urges careful examinations of the ears in all diseases.

Gun-Shot Wounds by the Reduced-Calibre Rifles in the Santiago Campaign.—Major Louis A. La Garde, who thoroughly tested the Krag-Jorgensen rifle or present service gun, compares the results of his experimental work with what was observed in the Santiago campaign, and concludes that the experiments and conditions found agree, and that, in addition to other advantages claimed by Professor Hebler for the reduced-calibre rifle, it possesses the greatest advantage of all, that the wound produced, though sufficient to disable, is much more humane than that produced by the old-style projectile.

A Rhode Island Philosopher.—A biographical sketch of Elisha Bartlett, by William Osler.

Philadelphia Medical Journal, January 20, 1900.

Case of Tuberculosis of the Kidney without Marked General Symptoms.—J. M. Da Costa reports the case of a man twenty-three years of age, who did not appear to be ill, whose only symptom was a sudden pain in the region of the kidneys lasting two weeks, accompanied by fever and weakness. The diagnosis of renal tuberculosis was made after finding the tubercle bacillus in the urine.

The Absorption of Iron from the Gastro-Intestinal Tract, and the Dietetics of Anæmia.—John C. Hemmeter discusses anæmia due to (1) food deficient in iron, (2) the presence of an excess of sulphur compounds in the digestive tract, and (3) a disturbance of metabolism. When iron is indicated, he advises recourse first to the inorganic compounds.

An Outline of the Principles of Malpractice as Related to Medicine and Surgery.—William C. Woodward defines malpractice as conduct on the part of the physician which does not conform to certain standards and which results in the injury of the patient. The unjustly accused physician has practically no redress.

Origin, Development, and Degeneration of the Blood-Vessels of the Ovary.—An abstract of a lantern demonstration by John G. Clark. The author ascribes the cessation of ovulation and the menopause to a gradual impairment of the vascular systems of this organ.

A Pneumatic Sigmoidoscope.—William V. Laws describes an instrument for inspection of the upper part of the rectum and the sigmoid flexure after inflation with air.

Creolin Poisoning.—E. W. Pressly reports a case in which poisoning followed rectal irrigation with a one-per-cent. creolin solution.

Journal of American Medical Association, Jan. 20, 1900.

City Milk Routes and Their Relation to Infectious Diseases.—Ernest Wende advocates the registration of city milk routes as the most certain way to insure the purity of the supply. He gives instances of epidemics in the city of Buffalo which were in this way traced to their true source and promptly checked. He says that while chemical analysis and bacteriological tests are both of great utility, the register takes the place of all in its importance and possibilities in the way of prevention of milk epidemics.

Typhoid Fever in a Leper, Following Immediately but Accidentally on Treatment with Antivenomous Serum.—J. F. Schamberg reports this case as interesting because there is no recorded instance of the simultaneous existence of these diseases. The patient recovered from the typhoid, his original disease remaining entirely unaffected by either that or the serum injections.

Ectopia Lentis.—C. P. Pinkard reports two cases of this disease which he examined in 1893. The writer says that the outcome of these cases, being so characteristic of certain changes in the zonule, warns us to be careful in our prognosis as to the possible inheritance of this disease by the children.

The Present Status of Surgical Tuberculosis.—Ralph Elmergreen reports three cases: one of tuberculosis of the skin, another of tuberculous lymphadenitis, and the third of tuberculosis of the epiphysis of the femur resembling sarcoma.

Extension Massage of the Ossicles with a New Aural Masseur.—Hamilton Stillson describes this instrument, which he has used for the last ten years with excellent results in the treatment of certain forms of deafness.

The Physician in Hawaii.—E. S. Goodhue presents notes of some experiences while government physician and medical superintendent of the Government Hospital in Hawaii.

Sarcoma of the Face and Temporal Region.—By Joseph H. Branham. See MEDICAL RECORD, vol. lv., p. 880.

Influence of the Medical Practitioner on Medical Progress.—By Joseph D. Bryant. See MEDICAL RECORD, vol. lvi., p. 635.

Surgical Treatment of Perforation of the Bowel in Typhoid Fever.—By W. W. Keen. See MEDICAL RECORD, vol. lvi., p. 641.

The Lancet, January 13, 1900.

A Mode of Operating in Appendicitis.—C. B. Keetly describes a mode of operating which he believes is adapted for use on any day or at any stage of an acute or subacute attack, though not indicated in every case. The skin and external oblique aponeurosis are incised above the anterior superior spine and the outer half of Poupart's ligament, parallel to the latter. Deeper muscles are penetrated by separation of their fibres and toward the outer part of the incision with scissors. The transversalis fascia is divided, and the peritoneum carefully separated from the iliac fascia, the surgeon palpating for the deep surface of the appendix or surrounding inflammatory products. A strong light is thrown into the wound and the signs of pus (infiltration of tissue, etc.) are looked for. If pus is found, the infiltrated tissue is torn open with two pairs of dissecting-forceps. In all cases two drainage tubes are carried to the bottom of the wound. The douche and syringe are avoided.

Volkmann's Ischæmic Paralysis: its Treatment by Tendon Lengthening.—H. W. Page narrates a case illustrating this condition, which seems to be an old lesion with a new name. It is the paralysis ensuing in the forearm from prolonged immobilization in fractures by apparatus which impedes the free circulation through the part: hence the term ischæmic. Page alludes to the difficulty in restoring the muscular structures to functional activity in these cases, and describes the wasting and other trophic disturbances which ensue. In the case alluded to, he exposed the flexor tendons at the wrist, each one in turn being split longitudinally, severed to the right and left at the opposite end of each incision, extended, and sutured with silk in the usual way. While entire recovery of function has not yet been realized (one year), results in the case have been extremely gratifying.

Diet in Typhoid Fever.—R. W. Marsden fed two hundred typhoid patients with milk, bread and milk with custard, fish with mashed potato, chicken, bread and butter, and finally minced meat. In the series of cases diarrhœa was absent throughout in sixty-one; in twenty-nine, though it was present when fish was given, there was no interference with its steady improvement; and in one hundred and seven, in which it was present, it was not increased by diet. Hemorrhage occurred six times, in no case being fatal. No case of perforation occurred. Relapses were noted in forty-eight. In one hundred and eighty there was not the slightest evidence of any alteration in the temperrature due to ingesta. Marsden believes that there is no justification for resisting a craving appetite in the manner at present in vogue.

Malaria and Mosquitoes.—G. Bastianelli and A. Bignami maintain that energetic treatment with quinine from the commencement of the infection of the malarial fevers has a great importance for general prophylaxis, since the parasites by its means can be prevented from developing into those forms which continue their life in the Anopheles.

Hypothermia.—E. B. Hulbert narrates the case of a man, aged thirty-six years, admitted to hospital for chronic headache and drowsiness. Syphilis was denied, and no gross lesion could be discovered on autopsy ten weeks later. Interest centred upon his temperature range. It ran from 81.6° F. (rectal) to normal and a little above. An epitome of the literature of subnormal temperature is given.

A Simple and Trustworthy Method of Quantitative Estimation of Mercury in Urine.—H. Schumacher and W. L. Jung advocate the addition to the suspected fluid of stannous chloride and the pouring of the resulting mixture on an asbestos filter containing gold. The filtrate is clear, and the whole of the mercury is retained by the gold asbestos. The latter is dried, weighed, and then ignited, the loss equalling the mercury in the given quantity of fluid.

Poisoning by Corrosive Sublimate in a Pregnant Woman.—M. D. Eder records a case in which thirty grains of the sublimate were taken by mistake. The woman was six months pregnant: prompt intervention saved her life, and she was delivered of twins at full term. A severe hemorrhage occurred two hours after delivery, but was controlled.

A Case of Enormous Nasal and Post-Nasal Polypus: Paralysis and Death.—A. C. Mukherji describes a case occurring in a young Mohammedan who refused operation and died apparently from the effects of pressure upon the brain by the mass. The nature of the polypus is not stated, but in places it was cartilaginous.

Prescribing Alcohol against Our Own Interests.—F. C. Coley believes that physicians should do all possible to discourage the use, in every way, of alcohol among the poor. The latter will then have money enough to employ a physician when sick, and thereby the abuse of medical charity will be greatly lessened.

Protracted Gestation.—J. Phillips records the case of a primipara, aged seventeen years, in whom confinement took place on the three hundred and twenty-third day after her last period, and three hundred and sixteen days after coitus.

Cancer of the Penis.—Marmaduke Shield prefers for this affection the operation of Gould, and condemns the use of the hot galvano-écraseur wire. He details his personal experience with six operative cases.

British Medical Journal, January 13, 1900.

A Case of Excessive Hemorrhage from a Varicocele of the Labia Majora.—In this case reported by J. E. Rosenstein, the patient, a young married woman, four and a half months pregnant, had always been well until the bursting of the varicocele while she was stooping to remove a shoe. There was no evidence of heart trouble, and no trace of varicose veins was to be found elsewhere.

Hypodermic Administration of Mercury in Syphilis.—W. Hubert S. Fosbery reports two cases in which he used intramuscular injections of 7 minims of mercurial cream made according to the formula of Surgeon-Major Lambkin (about one part of mercury to four of excipient). The writer found this preparation too strong, causing pain and mercurialism, although effective as regards the syphilis.

Carcinoma of the Ascending Colon and its Treatment.—W. McAdam Eccles reports two cases of this disease tending to prove that for the success of a colectomy it is almost essential that the operation should be performed before the chronic obstruction has become an acute one, and also showing with what success the mass can be dealt with extraperitoneally.

Concussion of the Retina.—Sydney Stephenson gives notes of retinal changes noted in the case of a boy who had been struck in the eye with a cricket ball. Similar retinal changes were first noted several years ago by R. Berlin, who described a series of cases.

A Case of Rupture of the Ureter or Renal Pelvis.—E. Percy Paton reports this case, in which recovery took place after lumbar incision and drainage, which procedure the author prefers in most cases to an immediate nephrectomy.

Enterectomy for Gangrenous Hernia.—W. P. Montgomery reports two successful cases of resection and primary suture in gangrenous hernia. These cases were both operated on in the Manchester Royal Infirmary.

Valvular Drainage Tubes in Empyema.—William Williams presents a diagram of an apparatus for draining or pumping out an empyema, and reports a case of tuberculous empyema in which this tube was used, resulting, as far as the writer could ascertain, in the first cure in a case of this kind.

Acute Orchitis in an Infant Eleven Weeks Old.—In this case, reported by F. Ashton Warner, the cause of the orchitis could not be found. It recovered completely after treatment with opium internally, hot followed by cold fomentations, and support of the scrotum.

Fracture of Both Clavicles.—James Battersby reports a case of this unusual double accident, a man engaged in shunting railroad cars having been struck on both shoulders by the buffers of two cars, which were being shunted against one another.

Rectal Feeding in Exhaustion following Children's Ailments.—Christopher A. A. Coulthard has found nutrient injections by the bowel very valuable in the case of children suffering from extreme exhaustion following diarrhœa.

A Calcified Lipoma in a Hernial Sac.—R. A. Milligan describes this specimen, which he found while performing an operation for strangulated hernia. It was the size of a nut, so hard that it could not be cut with a knife, and the author had no doubt that it was calcareous.

Description of Ambulance for the Mounted Service.—T. F. S. Caverhill strongly advocates the provision of mounted bearer companies for cavalry brigades.

Retention of Menstrual Blood from Atresia of the Vagina.—The second of two clinical lectures by Charles J. Cullingworth.

A Century of Surgery.—A lecture by Christopher Heath.

Medical Press and Circular, January 10, 1900.

Otorrhœa.—Paul Range concludes his article on treatment. Paracentesis is indicated whenever yellowness, tenseness, and bulging outward of the tympanum shows the presence of pus. It is easy and harmless. The canal should be first washed with soap, then with alcohol, and then sprinkled with 1 : 1,000 bichloride solution. The incision should be made in the infra-umbilical region; the vertical cut being preferred. Simple otorrhœa is treated by expectation or by active attack, destroying the source of pus by chemical action, removal of necrosed tissues, etc. Irrigation of the canal is advised, but only by sterile solutions. Surgical intervention is indicated in cases in which no improvement has been obtained by antiseptic treatment; when the probe reveals the existence of osseous lesions; when a cholesteatoma is detected or suspected; when hearing is completely lost, so that no further damage can be wrought in this direction: and when there is the slightest symptom pointing to encephalic complication.

Diphtheria.—W. R. Smith gives the English statistics since 1855, when they began to be recorded. The mortality in recent years is not so high as a generation ago. The cat has been found by Klein to be susceptible—the lungs being chiefly affected. The disease can be transmitted by those apparently well. The most fatal form is that associated with the streptococcus group. The majority of patients seem to retain the bacilli in the throat from two to nine weeks, and in one in whom antitoxin was used they were found for over two hundred days. It is not unusual to find bacilli after the hundredth day.

Hepatic Multilobular Cirrhosis.—Murrell reports a case in which post-mortem findings showed a liver of four pounds and eleven ounces, wrinkled on its surface, tough, slaty in color, the microscope showing the fine-framed variety of multilobular cirrhosis. The patient had been well until four months before admission, when he noticed blood in the stools followed by ascites and jaundice.

The Hyssop.—John Knott studies the botanical history, symbolism, toxicology, and therapeutics of the hyssop. There are two varieties, the Hyssopus vulgaris and Hyssopus infrequens. There are two kinds of the common garden hyssop, the ordinary and the white or red flowered kind, difficult to distinguish from each other. The medicinal advantages are questionable.

Deutsche med. Wochenschrift, December 21 and 28, 1899.

Speech and Sense Perception in Idiots. Kellner tabulates the results of the examination of 544 idiots. Of this number 291 showed defects in one or more of the special senses. The power of speech was wanting in 81, but of these 42 could understand what was said to them, and of the latter 5 were capable of work. In addition to these there were 15 deaf-mutes, and 11 had the use of a few words only. Sixteen were blind in one or both eyes; 170 were more or less color blind; 6 were very hard of hearing or totally deaf; the sense of taste was perverted or absent in 102; smell was wanting in 75; both taste and smell were absent in 34; sensation in the integument was defective in 105; and organic sensation (hunger, thirst, desire to evacuate the bladder or bowel, pain in abdominal troubles, etc.) was dulled in 68.

The Diagnostic Significance of Acute Exudations into the Abdominal Cavity.—H. Braun regards the occurrence of a rapid effusion into the peritoneal cavity as significant of a twist in the small or large intestine, especially the latter, or of strangulation of a knuckle of intestine in some abnormal opening, either congenital or formed by peritoneal bands, an adherent diverticulum, or the like; it is less common in cases of intestinal invagination, and does not occur in cases of obstruction by foreign bodies or tumors. Of course, in order that the sign may be of value one must be sure that the effusion has taken place rapidly and that it is not a case of long-standing ascites.

The Etiology of Epidemic Cerebrospinal Meningitis.—Leo Zupnik reports a case of this disease in which he isolated a diplococcus resembling Weichselbaum's meningococcus, but which on culture tests was found to differ from it. He reviews the literature of the subject, and comes to the conclusion that there is no unique specific etiological factor in epidemic cerebrospinal meningitis. The micro-organisms found in different cases of this disease are (1) Fraenkel's pneumococcus, (2) Weichselbaum's meningococcus, of which Pfaundler distinguishes two types, (3) the microbe isolated by the author and by Pfaundler, and (4) possibly also a meningococcus described by Kister.

Two Cases of Perigastritis Adhæsiva.—H. Westphalen and W. Fick report two cases of this condition in which Rosenheim's symptoms were well marked. These are: (1) The persistence of pain after thorough treatment of gastric ulcer with large doses of bismuth or with nitrate of silver, and (2) the absence of improvement following mechanical therapy when the latter has been indicated by motor disturbances of the stomach. Operative treatment is indicated only when the gastric function is interfered with by the adhesions and consequent fixation of the pylorus.

Renal Diabetes.—Eger reports two cases of chronic nephritis in which glycosuria occurred, but that the latter was due to an acute onset of renal insufficiency he does not venture to assert. He suggests, however, a more careful study of hospital material to determine this point, and thinks it not improbable that a suddenly occurring glycosuria may be found to be in some cases a symptom of renal insufficiency or uræmia.

A Case Showing the Necessity of Medical Inspection in Schools.—R. Lohnstein reports the case of a boy who had been operated upon successfully for congenital cataract. The child needed strong convex glasses, and with these could see quite well. He had been sent away from the public school and placed in a school for the blind. He was readmitted to the public school on the author's certificate, but was quickly returned to the blind asylum by the teacher.

A Death Under Ether.—J. Schneider reports a case of this nature. The patient had a very weak heart with marked excentric hypertrophy of the left ventricle, advanced arteriosclerotic changes, contracted kidney, and cirrhosis of the liver, and the author thinks the ether had little to do with the death specifically, and it would be better to describe the case as one of death during rather than from ether narcosis.

Renal Diabetes.—Paul Friedrich Richter has made a number of experiments with cantharidin, corrosive sublimate, and other kidney poisons, the administration of which is followed by glycosuria. He also cites a few cases from medical literature which would seem to point to the existence of a glycosuria of renal origin.

The Origin of Leucocytosis.—P. Lengemann discusses the production of leucocytosis through changes in cells emigrating from the bone marrow.

Wiener klinische Wochenschrift, December 28, 1899.

The Influence of the Mechanical Irritation of the Liver on the Heart.—M. Heitler states that the relation between the liver and the heart, in the sense that disturbances of the heart occur through disturbances of the liver, has long been known. Recently de Giovanni and Potain have made careful investigations in this direction. A definite symptom complex in the lungs and heart has been shown to be dependent on disturbances of the stomach and liver, oppression, dyspnœa, a feeling of suffocation, dilatation of the right heart, and further consecutive changes. Heitler finds, with a large area of heart dulness and a small pulse, a large area of liver dulness and spleen dulness, and vice versa. He also finds that if he strongly percusses or shakes the liver, the pulse, which was previously small, immediately becomes large and full and the area of heart dulness is decreased.

The Dietetic Treatment of Diabetes Mellitus.—Rudolf Kolisch advocates a strict vegetable diet which he has modified for the special use of diabetic patients. This diet has many times met with excellent results in severe cases. The vegetable diet keeps the body in good condition with the least possible expenditure of heat and the least disturbance of nutrition. This diet also supplies to the organism more carbohydrates than is possible with a meat diet. The first result of the vegetable diet in the diabetic is a decrease in the quantity of urine. Often acetone and acetic acid disappear from the urine. For light cases a mixed diet has proved beneficial. He considers an exclusive milk diet to have very good results in diabetes.

The Relations of the Anterior Corpora Quadrigemina to the Eye Movements.—S. Bernheimer finds from experiment that the anterior corpora quadrigemina are neither a reflex centre for the eye movement, nor do the neurons to the cortex pass through them. The connecting neurons from the nuclei of the eye muscles to the periphery of the angular gyrus all decussate. The decussation must be in the median line under the surface of the aqueduct of Sylvius, for after taking away the anterior corpora quadrigemina the synergistic eye movements emanating from the angular gyrus remain just the same, and apes, after their anterior corpora quadrigemina are destroyed, still have perfect and spontaneous eye movements.

New Experiments Concerning the Absorption of Casein.—Wilhelm Knoepfelmacher declares as a result of new experiments that a part of the casein phosphorus in the fæces is separated out unused.

Berliner klinische Wochenschrift, January 1, 1900.

Artificial Production of Gout.—H. Kionka calls attention to the fact that gout is observed in certain animals and birds as well as in man. In the common fowl of the barnyard, gouty manifestations may be produced by the introduction into the body of chromic, oxalic, and carbolic acids, acetone, aloin, sublimate, and sugar candy. Kionka was led to experiment along this line, and placed a number of hens under good conditions, confining them entirely to a diet of chopped lean horse-flesh which was fed to them twice daily. They were able to drink as much water as they wished. After a varying interval averaging about four months (during which time the fowls appeared perfectly well) they began to show evidences of a disease which gradually assumed the characteristics of true gout.

New Words and New Conceptions in Pathology.—R. Virchow speaks of the signification which has been given to various medical terms in the past, and calls attention to the modifications in meaning necessitated by the growth of our pathological studies and their results. He admits that he himself has been responsible for the introduction into the nomenclature of pathology of not a few new words, but finds his justification in the fact that they were needed. The fact, too, that they have been received by the medical world without protest confirms the wisdom of his choice of terms.

Operation for Fibroma of the Mesentery with Extensive Resection of the Small Intestine.—E. Lexer describes the case of a man aged forty-one years from whose abdomen a fibroma attached to the mesentery was removed along with over six feet of intestine. The greatest measurement of the tumor was 25 cm. and its weight five pounds. The patient was up on the twentieth day.

Endemic Bath-Conjunctivitis.—Fehr alludes to a group of cases of conjunctivitis seen in one of the eye institutions in Berlin. Investigation showed that the patients all lived in the same locality and frequented the same public bath. The disease seemed to be an infection and at first was mistaken for trachoma. Closing of the bath checked the spread of the malady.

A Contribution to the Character, Course, and Treatment of the Recent Epidemic of Trachoma in Berlin.—P. Schultz insists upon the necessity of a more frequent renewal of the water in the swimming pools of the public baths in Berlin. A description is given of the methods employed to bring the epidemic mentioned to a close.

The Significance of Glycuronic Acid in the Phenylhydrazin Test in Urine.—P. Mayer does not believe that the presence of this acid in urine vitiates at all the value of the phenyl-hydrazin test for glycosuria.

A Case of Chyliform Ascites in Syphilitic Cirrhosis of the Liver.—By V. Poliakoff. See Medical Record, vol. lvii., page 29.

Bulletin de l'Académie de Médecine, December 26, 1899.

The Respiratory Reflex and its Fundamental Mechanism in the Cardio-Respiratory Function, as Demonstrated by Radioscopic Observation.—J. V. Laborde describes an experiment upon a dog, in which every step in the process of asphyxiation by means of a cannula with a stop-cock introduced into the trachea was observed in detail, thanks to the *x*-rays. When the animal was at the very point of death, rhythmical tractions of the tongue, without the introduction of air through the cannula, restored the respiratory and cardiac mechanism. The introduction of air then brought the apparently dead animal back to life.

Remote Results of Perineal Urethrectomy.—M. A. Poncet describes an operation which has for its object the formation of an artificial perineal meatus, and reports excellent results in twenty-three cases in which the operation was performed two, three, five, and even seven years ago.

Multiple Sebaceous Epitheliomata.—Poncet, Léon Bérard, and Lumière report the case of an old man who for forty years has suffered from tumors of the sebaceous glands which from an anatomico-pathological standpoint are epitheliomata.

La Riforma Medica, December 21–28, 1899.

Variety and Significance of the Encapsulated Bacilli Frequently Found in the Diseased Nasal Mucosa.—A. de Simone examined the nasal secretion in fifty cases of catarrhal rhinitis, and succeeded in isolating thirty-five kinds of encapsulated bacilli, some of them possessing the culture characteristics of the bacillus mucosus, some of Frisch's bacillus, and others of the pneumo-bacillus. He believes that these bacilli, which so frequently lodge in the pharynx, migrate into the nasal mucosa, and then cause the disturbances which many writers have supposed to be due to some special variety of micro-organism.

Apyretic Fevers.—G. B. Ughetti says that the title of his article sounds like a contradiction of terms, but insists that fever does not necessarily mean high temperature. He describes cases of typhoid, etc., in which there was hyperthermia, and gives it as his theory that in infective apyretic fevers there is usually such an immense amount of toxin produced, either from the specific agent or from associated microbes, that their constant hyperthermic effect is counteracted in some way as yet unknown.

Vratch, December 25, 1899.

The Influence of Suprarenal Preparations in Addison's Disease.—L. A. Kushnir reports two cases of Addison's disease in which he made a careful study of metabolism and of the influence upon it of preparations of the suprarenal body. In this affection, he says, metabolic activity is reduced, but it is increased by the administration of suprarenal extract. He found the action of this drug was to increase the rapidity of the pulse and respirations, and to reduce the appetite. There was no improvement whatever in the patient's condition; the pigmentation of the skin continued and the asthenia increased from day to day. The conclusion was that there is nothing to hope for in the administration of suprarenal preparations in Addison's disease.

Supervision of Prostitution in the Kazan Government in 1897–98.—N. N. Poroshin presents a statistical study of prostitution, its causes and sanitary aspects.

French Journals.

Eosinate of Sodium in the Treatment of Epilepsy.—Bourneville and Chapotin have undertaken a series of therapeutical studies upon the composition of the eosinate, and upon the hypothesis of Le Goffe and Sainton. The practical results obtained by them differ from the theoretical hopes as to the advantages of the remedy. In various experiments the drug was given in does of 25 cgm., gradually increased until in the ninth week 3 gm. were administered. A series of tables and observations upon the various forms of epilepsy are presented. In ninety-four per cent. of cases accidents implicating the skin chiefly were noted, but these did not occur when less than 2 gm. were given. The lesions consisted chiefly in redness followed by swelling of the face and hands. Later under slight traumatisms atrophic troubles of severe nature may come on, with ulceration, etc. The eruptions differ, as a rule, from those produced by bromism.—*Le Progrès Médical*, December 30, 1899.

The Therapeutic Problem of Regeneration of Organs.—Paul Carnot refers to his work published last year. From a general point of view we may say that every time an organ has been profoundly implicated, the only truly curative therapeusis consists in replacing anatomical elements irreparably damaged by new cells. The regeneration of organs constitutes the natural process of cure, developed especially in the inferior animals and in the young. He studies the influence of mechanical agents on cellular proliferation, the influence of infectious agents and their toxins, the influence of nutritive materials on the proliferative activity, and he concludes by showing how far we are from a complete solution of the problem.—*La Presse Médicale*, January 6, 1900.

Hydrotherapy in Infancy.—J. Combe studies the question of cold-water bathing, whose adversaries are becoming more and more scarce, in fevers and acute diseases. He gives indications and contra-indications. He thinks that sea-bathing or sea-air is very beneficial in chronic diseases, especially for city children, but should be avoided in the nervous, excitable, hysterical, epileptic, and choreic children. Also when they suffer from blepharo-conjunctivitis, keratitis, otitis, bronchitis, rheumatism, heart disease, eczema, pertussis, and itching affections, they should be removed from the sea-side. Rachitic and scrofulo-tuberculous children should remain months and even years. Repeated sojourns are probably more beneficial than prolonged stays.—*La Médecine Moderne*, January 3, 1900.

The Danger of Administering Chloroform in the Presence of a Gas-Flame.—G. Maurange refers to the dangers pointed out by Catrin based upon an article in *The Lancet*, and goes on to give his personal experience in a number of instances in which chloroform, administered in a closed room with the gas burning, produced in the attendants mucous-membrane irritation with cough, dyspnœa, and a feeling of malaise. The intoxicating agent is the chloride of carbonyl, the phosgene gas of Sir Humphry Davy, one of the products of decomposition of chloroform evaporating in the presence of the flame.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, December 31, 1899.

Traumatic Intra-Peritoneal Rupture of the Bladder.—J. Vichard reviews the whole question, and, in conclusion, agrees with Pousson that, after having sponged with care all tissues touched by the urine, the attempt should be made to suture the bladder in two planes, one for the mucous and muscular coats and the second for the peritoneum, unless, for instance, the mucous membrane has been too much injured. Catgut is employed for the first plane and silk for the second.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, January 7, 1900.

Complete Section of the Median Nerve at the Wrist; Suture; Cure.—Albert Monchet gives the result of operation in a girl aged thirteen years, whose wrist was cut with glass. The tendon of the palmaris longus was found cut through; it was sutured, and after three or four months the wound opened, and the silk was thrown off; after which permanent healing took place.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, January 4, 1900.

Tuberculosis in Workingmen.—Grandmaison says no occupation is exempt from tuberculosis, and he bases his studies on thirty-five patients taken from various employments. Closed working-rooms are the chief centres for dissemination. Sanatoria are advised for the laboring classes, but they will always be insufficient to accommodate all. It is scarcely within the bounds of realization that a city can protect itself against the dissemination of this disease by the working classes.—*La Presse Moderne*, January 3, 1900.

Senile Atrophy.—Weinberg give a résumé of a critical study which Metchnikoff has himself made during the past year of his researches relating to the prevention of senility. Documents are still too few to determine the cause and mechanism of senile atrophy. It is to be hoped that the day will come when serums obtained by the aid of appropriate elements may counteract atrophic and hypertrophic lesions of organs.—*La Presse Médicale*, January 6, 1900.

Dysenteriform Enteritis.—H. Roger gives a bacteriological research into the cause of an epidemic of dysentery nostras, illustrated with culture results. He describes a bacillus differing from those previously found, and thinks his observations show the existence of a special form of dysenteriform enteritis.—*La Presse Médicale*, January 3, 1900.

The Physician and Surgeon, December, 1899.

The Contagiousness of Pulmonary Consumption.—Ernest L. Shurly questions whether tuberculosis is contagious in the ordinary acceptation of the term, and does not believe that the individual right of patients should be prejudiced by the method of reporting his name or quarantining him. He agrees with Professor Hueppe that strict cleanliness, fresh air, and proper marriage relation will do more toward the prevention of tuberculosis than any quarantine measures. In any case it is for the medical profession and not for sanitary boards of laymen to decide the matter.

Sympathetic Ophthalmia.—M. R. Beaudoin-Bennett thinks that in this affection operative interference has no place, the only admissible operation being scleral incision or puncture after the subsidence of the acute symptoms, if there is extreme tension.

Uterine Fibroids.—W. P. Manton believes that when these growths cause pain, hemorrhage, and discomfort, medicinal and electrical treatment means time wasted, and eradication is the only rational measure.

Tuberculosis of the Peritoneum.—Hal C. Wyman reports and describes several cases of this nature The leading feature was always an ascites not to be accounted for by other diseases.

A Survey of Modern Therapy.—Frederick McD. Harkin thinks that if we will endeavor not to overdose our patient, and if he has an enduring constitution, he will very likely get well in spite of our medication.

Conservatism in Medicine and Surgery.—By Frederick W. Robbins. The retiring president's address before the Detroit Academy of Medicine.

A Case of Hip-Joint Amputation by Wyeth's Bloodless Method.—By R. B. Baird and G. L. Cornell.

Medicine, January, 1900.

A Study of Aural Vertigo.—Lewis S. Somers states that vertigo may be objective or subjective, two groups of phenomena being invariably associated with the affection, the first being the motor disturbances, the second circulatory. Aberrant vasomotor disorders are frequently noted, such as sweating and superficial congestion, while nausea and weak pulse are quite frequent. Anæmia, hyperæmia, and inflammatory changes may cause vertigo. It may be of cerebral or ocular origin. It may depend upon disorders of the viscera or toxæmia. The sudden suppression of long-continued discharges is sometimes attended with this symptom, and it also takes place in lithæmia, while reflex vertigo may result from affections of the stomach and uterus. The labyrinth is an indispensable factor in its production.

Some Considerations in Sugar Testing, with Description of a Method for the Detection and Estimation of Sugar in the Urine.—Arthur R. Elliot submits the following reagents:

1. Sulphate of copper, c. p.	gr xxvii.
Glycerin, c. p.	ʒ iij.
Distilled water	ʒ iiss.
Liquor potassæ q.s. ad	℥ iv.

Dissolve the sulphate of copper in the glycerin and water; gentle heat will facilitate solution. When cool, add the liquor potassæ, mix thoroughly, and filter. 2. A saturated solution of c. p. tartaric acid in distilled water. Method: A drachm of No. 1 is brought to the boiling-point in a test-tube; 3 drops of No. 2 are added and the solution is boiled again. The urine is added drop by drop, boiling and shaking the test-tube after each addition until reaction. If no change follows the addition of eight drops of urine, sugar is not present.

Nursing in the Lying-in Period.—Gustav Kolischer calls attention to a few important points to be observed in nursing during the puerperium. He approves of the administration of ergot after confinement. Micturition should be watched but the catheter avoided if possible. If there is pain in the pelvic articulations, a firm bandage should be applied. Fissures of the areola of the nipples should be cauterized. If the bowels are obstinate the faradic current should be employed.

Spondylitis Deformans, Spondylarthritis, or Osteoarthritis of the Spine.—O. M. Steffenson considers this a chronic affection of the vertebræ, producing osteophytes between their articular surfaces, which terminates in partial or complete ankylosis of the spine. Efforts at increasing the nutrition of the patient, and the use of tonics, are followed by the best results.

Secondary or Membranous Cataract.—Henry D. Noyes describes the operation through the sclera by the knife-needle for secondary cataract. He commends the method for general adoption in this affection, having found it, from his own experience, practically devoid of serious risks.

Serious Heart Disease Without Rheumatism; A Further Report.—A. L. Benedict declares that while rheumatism is especially related to endocarditis, nevertheless, scarlet fever may produce the lesion as well as the other infectious diseases. To support his statement he reports a number of cases.

Annals of Surgery, January, 1900.

The Employment of Local Anæsthesia in the Radical Cure of Certain Cases of Hernia, with a Note upon the Nervous Anatomy of the Inguinal Region.—Harvey Cushing tabulates notes of thirty cases of hernia operated upon under cocaine anæsthesia. Interesting diagrams are given showing the areas of anæsthesia produced by the injections. The solution employed was cocaine mur. 0.1, morph. mur.

0.02, sodii chlor. 0.2, aq. dest. ad 100. The advantages are absence of vomiting and retching, less liability to urinal disturbances, rare necessity of catheterization, and ability to operate safely in patients who would not bear a general anæsthetic. The disadvantages are the longer time required for operation and the infliction of a certain amount of pain.

Note on Mortality After Operation for Large Incarcerated Herniæ.—H. O. Marcy reports two fatal cases. The object of the paper is to discuss how we are to determine the danger to life because of the increase of intra-abdominal pressure. When any considerable portion of the abdominal contents has been for a long time displaced, Marcy thinks it advisable to keep the patient for quite a while in bed with a limited diet and moderate purgation: this lessens the amount of abdominal contents and thereby occasions a corresponding reduction in the hernial contents to be returned. In even a greater degree will the abdominal wall be thinned and relaxed.

The Surgical Aspects of the Modern Small-Bore Projectile.—A. Schachner discusses the change in the character of projectile wounds as illustrated by recent wars, and considers the conditions governing the behavior of projectiles in general. He sums up the results of his discussion in thirteen distinct conclusions, emphasizing the fact that the rotary action of projectiles may continue after the penetrative action ceases, and that the character of the wound is partially dependent upon this rotation.

On Vesico-Urethro-Vaginal Fistula.—J. S. Horsley describes a successful operation for this lesion done on a primipara of twenty-two years. Nearly all of this class of cases require several operations before cure is complete.

Mammoth Ovarian Tumors.—By J. B. Bullitt. See Medical Record, vol. lvi., p. 570.

British Journal of Dermatology, January, 1900.

Multiple Epithelioma Developing upon Lupus Erythematosus.—J. J. Pringle adds one more to the extremely limited number of cases in which epithelioma developed upon a patch of lupus erythematosus. Among previous cases two have been reported in this country, one by Riesomeyer in the *St. Louis Courier*, 1886, and one by J. D. Wyer, in the *Texas Medical Journal*, 1892–93. Dr. Taylor, of Liverpool, has seen two cases, and Kreibich, Kaposi's assistant, is about to publish an instance, from which quotations are made from the advance sheets.

A Case of Chronic Interstitial Nephritis; Dermatitis Exfoliativa; Uræmia; Death.—Sir Dyce Duckworth relates the history of a woman who died with uræmic symptoms after presenting the signs of pityriasis rubra, or dermatitis exfoliativa, such as is usually encountered in elderly people.

Pediatrics, January 15, 1900.

An Enlarged Liver in Rickets.—R. Turnstell Taylor reports the case of a boy, two and a half years of age, who, up to the age of one year and nine months, seemed healthy. He then had fever, followed by Parrot's paralysis, and the diagnosis of rickets was made. On admission, the case was a typical one of rickets. Everything was against the specific origin, but because improvement did not take place under other means inunctions were begun, when improvement was rapid and progressive. The case, the author thinks, points to a relationship between syphilis and rickets, and suggests, in all cases of rickets in which the liver is enlarged, that antisyphilitic treatment should be instituted, although the history may be negative as to its specific nature.

A Case of Patent Meckel's Diverticulum.—R. Abrahams gives an instance in which during the first week it was noted that the cord became inflated at its distal end when the baby cried. The cord soon fell off, when an elongated mass, an inch and a half long, protruded from the umbilicus, simulating highly congested mucous membrane. A probe passed into its central opening entered the abdominal cavity, and when it was withdrawn fæces were seen upon its tip. Fecal matter and flatus escaped. The tumor was ligated and excised, and the stump cauterized, with resulting cure. Four months later the diverticulum was found still closed.

Alveolar Catarrh in Children.—J. C. Gettings and Charles H. Judson relate instances of this condition, which was described by Douglas Powell. They also present the conclusions reached by Duerck and Beco. They suggest the possibility that alveolar catarrh may originate and run its course without the agency of the tubercle bacillus, that the lesion resulting may offer a suitable nidus for the growth of the bacilli, and, though the number of cases is small, the physical signs are sufficiently definite to warrant a classification under this heading.

Congenital Lateral Curvature of the Spine.—Henry Ling Taylor reports two cases of this deformity in children aged three months. Ketch made a study of two hundred and twenty-nine cases and found that a great number occurred before the age of twelve years, and Eulenberg found five cases under one year of age in one thousand examined.

Deutsche Aerzte-Zeitung, January 1, 1900.

Carbonic Oxide in Tobacco Smoke.—C. Binz says there are three kinds of poison in tobacco smoke; (1) nicotine; (2) that which is obtained by the slow ash formation, pyridin, etc.; (3) carbonic oxide. The results of his studies of the question are given in the following conclusions: (1) Carbonic oxide is always easily shown to be present in tobacco smoke. (2) Its percentage, depending upon the volume of the smoke gas, varies between 0.6 and 7.6. The variations depend upon the rapidity of the ash formation and the quantity of atmospheric air drawn in or the lung-air blown out. (3) A never-so-slight acute poisoning from carbonic oxide of tobacco smoke is, under ordinary conditions, scarcely to be expected. (4) Whether the daily taking in of the small quantity of carbonic oxide which, through many years of smoking, gets into the blood of smokers, cannot set up a chronic injury, is a question still to be settled. For the qualitative determination of small quantities of carbonic oxide in the blood the test with tannin in definite watery solution, and at a temperature of about 40° C., is better than that by the spectroscope alone or that with the spectroscope and ammonium sulphide.

Tetanus and its Treatment.—E. Stadelmann says that in a disease like tetanus, which may recover spontaneously, a definite conclusion as to the result of serum treatment is difficult to establish. The views of von Jaksch and others are given, and four cases are briefly related. Ordinary tetanus he believes starts from the spinal cord and not from the brain. It is, therefore, rational treatment to inject the serum into the canal, and in the future it is his intention to inject part of the serum into the vein, and part intradurally by lumbar puncture.

Pneumothorax in Secondary Sarcoma of the Lungs.—Ulrich Rose quotes the statistics of Bich, who shows that malignant tumors of the lungs are rare precursors of pneumothorax. Out of twenty-one cases of pneumothorax one showed multiple secondary sarcoma of the lung as the cause in a woman forty-five years of age. Morphine is here naturally to be advised more than in any other form of pneumothorax.

Zeitschrift für Diät. u. Phys. Therapie, December, 1899.

Treatment of Nephritis with Mineral Waters and Baths.—Felix Schlagintweit has treated one hundred cases of Bright's in various forms and stages at Brückenau. In chronic diffuse nephritis the diuresis is markedly increased, and the specific gravity rarely shows a tendency to fall. There is usually a decrease in albumin, sometimes an increase. After the administration of mineral waters and milk the specific gravity and percentage of albumin may vary thus: (*a*) Specific gravity sinks, albumin remains the same; (*b*) specific gravity and albumin sink; (*c*) specific gravity sinks, albumin increases; (*d*) specific gravity increases, albumin remains the same; (*e*) specific gravity and albumin increase; (*f*) specific gravity and albumin remain the same.

The Border Line of Normal Temperature.—Marx concludes that (1) the temperature in health is normally under 37° C., and usually between 36 and 37° C. (2) Occasional rises of 37.2° C. are observed in health, but are attributable to special circumstances (indigestion, fever). (3) Temperatures above 37.2 C. are usually combined with subjective symptoms and thus out of the normal. (4) Temperatures under 36° C. occur without collapse. (5) Many phthisical patients have temperatures varying within the normal boundary.

Fermentation of Slowly Fermenting Sugars.—Ernst Bendix shows that such sugars as milk sugar, galactose, and xylose, which have heretofore been considered as slowly fermenting, or not at all capable of fermentation, are, after the addition of various organic substances (pancreatic powder, organ powder, liver powder, spleen, ovarian, and intestinal powders) easily fermented by certain bacteria.

Experimental Observations upon the Excretion of Hydrochloric Acid in the Human Stomach with Various Food-Stuffs.—Chr. Jürgensen and J. Justesen give at length secretory phenomena of the stomach with various food-stuffs, as shown from experiments. The gastric contents were aspirated at various periods and tested. A table of cases and charts accompany the article.

Bathing and Swimming from a Hygienic Standpoint.—Julian Marcuse claims that bathing and swimming produce a variety of hygienic effects, which prove from a prophylactic standpoint an excellent protection against the invasion of disease. They perfect the skin, harden and strengthen the body, and benefit the heart, lungs, and nervous system.

Aix les Bains in Savoy: Sulphur Baths; Douche Massage.—Von Leyden gives a description of this bathing-place and its baths. Douche massage as practised here is described. Patients suffering from gout, asthma, chronic joint affections, neuralgia, paralysis, muscular atrophy, and syphilis seek treatment at this place.

Therapy of Impotence.—By J. Zabludowski.—See Medical Record, vol. lvii., p. 120.

Archives Générales de Médecine, January, 1900.

Glossodynia.—C. Chauveau classifies this affection in the following manner: 1, Glossodynia secondary to neuralgia of the trigeminal; 2 glossodynia of the insane; 3, tabetic glossodynia; 4, hysterical glossodynia; 5, rheumatism of the tongue muscles; 6, glossodynia from local causes such as dental affections, pharyngeal granulations, hypertrophy of the posterior pillars of the fauces or of the tonsil, lingual varices, chronic glossitis, and especially papillary hypertrophy of the "foliaceous region" first described by Albert. Pain is the chief symptom. The use of the galvanocautery is the best treatment.

Umbilical Tumors.—Nicolas Giannettasio reports a case in a woman, aged forty-four years. The tumor was the size of a walnut, and was situated partly within the umbilicus. It was removed and the patient made a good recovery, there being no trace of a recurrence two years later. The histological examination showed that the neoplasm was a fibrous myxoma. Many parasites belonging undoubtedly to the blastomycetes were found in the peripheric, growing portions of the tumor.

Unusual Resistance and Tolerance of the Organism and the Liver to Alcohol.—Dr. Follet reports the case of a man, aged forty-eight years, who died of pneumonia, who for thirty years had taken at least three litres of red wine daily, besides several appetizers. The liver, kidneys, and the organs were normal.

Caseous Infection in Pulmonary Tuberculosis.—M. Solles and M. Baillet, whose work is reviewed by Henri Benjamin, hold that the bacillus kills the phagocytes and transforms them into a mass of dead cells, *i.e.*, tubercles. As a result each tubercle is transformed into casein, which constitutes phthisis and causes death.

Laennec's Cirrhosis in the Preascitic Stage.—Emile Boix reports and describes a case due to alcohol and daily drinking of a litre of black coffee. It was cured by milk diet, calomel, and salol.

Preparalytic Hemichorea.—E. Boinet reports two cases of this rare affection, which bring the number up to thirteen of known cases due to hemorrhagic foci or to cerebral softening.

Origin of the "Charité" Hospital of Paris.—P. Tillaux gives the history of this celebrated institution, which is soon to be torn down by order of the municipal council.

Diseases of the Respiratory System.—By Louis Rénon.

Revista Ibero-Americana de Ciencias Méd., Dec., 1899.

Sciatic Neuritis.—M. Otero Acevedo gives the result of a study of 276 cases of sciatica, of which 203 occurred in males. There was one case in a child of eight years, and four in children from eleven to fourteen years of age; the greatest number of cases was in individuals between forty and fifty years old; only two of the patients were over seventy years of age. The most common cause was rheumatism (145 cases): then cold and wet (85), trauma (18), influenza (7), malaria (5), gout (2), and hysteria (1); in 13 cases the cause was not definitely recorded. The author makes a sharp distinction between sciatic neuralgia, which is purely a symptom, and sciatic neuritis, which is a disease. The neuralgia always precedes and accompanies the neuritis, and there are cases of the latter in which pain is the only symptom, but the pain of neuritis is deeper and more continuous than is that of neuralgia sine materia.

Treatment of Pneumonia at the Beginning and at the End of the Nineteenth Century.—Federico Rubio makes a comparison of the treatment of pneumonia at the beginning of this century with that in vogue at the present time. The main reliance of the therapeutist then was on bloodletting and counter-irritation. Now, some resort is still had to counter-irritation, but apart from that therapeutic nihilism prevails. In comparing the results of these two methods, the author inclines to regard the abandonment of bloodletting as a distinct loss; the practice was formerly abused, no doubt, but this is no excuse for the present neglect. The antiphlogistic treatment of the beginning of the century left the organism more weak, perhaps, but it left the organs with fewer lesions.

Phosphaturia.—F. Murillo studies a case in which the relation between phosphaturia and hyperchlorhydria was manifest, and concludes that in many cases the hyperchlorhydria is the determining cause of the phosphaturia. In the case reported, however, the patient was neurasthenic and arthritic, and the author believes that arthritism, which is thought by many to be the cause of neurasthenia, was also here the cause of the hyperchlorhydria. He opposes the view of Klemperer that phosphaturia is not a result of hyperchlorhydria, but is rather a manifestation of disease of the nervous system. He holds that the gastric disturbance and the nervous exhaustion are concomitant affections, neither dependent on the other, but both due to a precedent arthritism.

Surgical Neurology.—Eulogio Cervera reports two cases showing the benefits of surgical treatment in certain nervous affections, and demonstrating also the advances of modern surgery in the direction of greater conservatism. The first was one of degenerative lesions in the lower extremity following section of the sciatic nerve in a stab wound. An incision was made close to the cicatrix and the divided ends of the nerve were freshened and sutured. The man made an excellent recovery. The second case was one of dislocation of the ulnar nerve of eighteen months' standing, accompanied by neuritis. An incision was made, and the nerve was exposed and returned to the epitrochleo-olecranon gutter. The pain was relieved and the man recovered with full use of the forearm and hand.

A Gigantic Lipoma of the Neck.—Juan de la Sota y Lastra reports the case of a boy, eight and three-fourths years old, who had a tumor depending from the right side of the neck which rested in his lap as he sat on a chair. The circumference of the pedicle was 40 cm., of the widest part of the tumor 70 cm., and its weight was 7.8 kilos (over 17 pounds). The tumor was noticed at birth as a small projection the size of a hazelnut, and had grown steadily. The growth was removed and the boy made a good recovery. The microscopical diagnosis was a fibro-myxo-lipoma.

Anatomy of the Ethmoidal Cells.—P. L. Peláez Villegas says that the arrangement of the ethmoidal cells is exceedingly variable, and in consequence there is no regularity in the topography and arrangement of the openings leading to the frontal, maxillary, and sphenoidal sinuses. He proposes a new division of the ethmoidal cells in place of the classical division into anterior and posterior.

A Rare Lesion of the Hand.—Antonio Martínez reports the case of a woman whose left hand was greatly swollen; on the dorsum were several ulcers which gave exit to a lymphatic fluid, and the fingers were flexed. An incision showed the presence of sclerotic tissue, and then an investigation brought out a history of hereditary syphilis. The patient was subjected to an antisyphilitic treatment by mercurial inunctions and large doses of potassium iodide alternately, and a speedy cure was obtained. The author's diagnosis was syphilitic sclerosing periangitis.

The Book, the Review, and the Periodical.—Federico Rubio compares these three forms of scientific literature, giving the preference in general to the review over the book.

Application of the Experimental Method in the History of Medicine.—Under this title Luis Comenge gives a sketch of the early history of medicine in Spain.

Four Cases of Tubal Pregnancy.—G. Abascal reports four cases of this nature in which operation was performed at an early period.

An Operating-Table.—R. Martin Gil describes and pictures a new operating-table, the position of which can be varied in numberless ways.

Il Policlinico, December 15, 1899.

Experimental Researches into the Pathogenesis of Concussion of the Brain and Spinal Cord.—Francesco Saverio Cavicchia and Umberto Rosa in all their experiments have observed spasm of the blood-vessels in the early stages of concussion. Macroscopic and microscopic examinations have given absolutely negative results. The degenerative lesions observed by Schmaus and others they believe to be the result of more serious lesions in the spinal cord, rather than of simple concussion.

Ovarian Cysts.—Alberto Pepere concludes that in the genesis of follicular cysts, at least in a certain number of cases, the epithelial cells of the follicle play the chief part. Cystic adenomata may arise from the papillary residua of the hilum, or from the epithelium covering the superficies of the ovary. These new growths may become intensely malignant, while retaining their glandular formation. The majority of dermoid cysts are to be regarded as productions with an embryonal character of the ovum cell, rather than as fœtal inclusions.

The Treatment of Hemorrhage in Pregnancy.—J. Keogh Murphy considers that accidental hemorrhage is not due to external injury, but to disease of the uterus, often accompanied by kidney mischief. When contractions are present, rupture of membranes and delivery will suffice; when absent, vaginal plugging, uterine binding, and general stimulation should be used, until the cervix dilates sufficiently to allow of delivery. If internal hemorrhage continues, Porro's operation will probably have to be performed. Saline infusions, rectal, subcutaneous, or intravenous, can be used with good effect.—*Treatment*, December 28, 1899.

Irido-Choroiditis due to Intestinal Auto-Infection.—Elia Baquis reports a case in which the eye symptoms were clearly referable to prolonged attacks of enteralgia and obstinate constipation. That there is a close connection between intestinal lesions and diseases of the eye is well known. Given an infected area in any part of the organism, distant portions may be affected by living germs or their toxic products. In the case reported the author believes that the process was a chemical one. Toxic products of digestion, not having been eliminated, were absorbed into the circulation and injuriously affected the eyes.—*La Settimana Medica*, December 23, 1899.

Therapeutic Hints.

A New Combination for hypodermatic injection in syphilis is the following:

℞ Hydrarg. chlor. mit.	gr. lxviiss.
Orthoform	gr. xij.
Ol. petrolat.	ʒ iiss.

M. S. From fifteen to thirty drops can be injected; securing the analgesic effect of the orthoform.

—LOZA.

Vaginal Irrigation for leucorrhœa:

℞ Potass. chlorat.	12 parts.
Vini opii.	10 "
Aquæ picis	300 "

M. S. Add two or three drachms to a quart of warm water.

—LUTAUD.

In Mercurial Stomatitis.—

℞ Potass. chlorat.	ʒ v.
Sapo. medic.	ʒ iiss.
Calcii carbonat.	ʒ v.
Ol. menth. pip.	♏ xv.
Ol. caryophylli	♏ iv.

M. S. Use as dentifrice.

—*Practitioner.*

Neuralgia of the Face.—

℞ Butyl chloral hydrat.,	
Spt. vini rect.	āā ʒ iiss.
Glycerini	ʒ v.
Aquæ	℥ iij.+ ʒ vi.

M. S. A teaspoonful once or twice daily.

—*Progrès Médical.*

Cough in Phthisis.—

℞ Codein	gr. iss.
Terpin. hydrat	gr. xv.
Ext. hyoscyami.	gr. iss.
Ext. belladonnæ.	gr. $\frac{3}{4}$
Mas. cyroglossi.	gr. viiss.

M. ft. pil. No. x. S. One four times daily.

—*Journ. des Pratic.*

Digestive Infections in infants at the breast.

℞ Benzo-naphthol	0.30–0.50 cgm.
Cretæ præparat.,	
Bismuthi subnit.	āā 2–3 gm.
Mucil. acac.	60 "
Elix. paregoric	gtt. vi.–xij.

M. S. Shake and give a teaspoonful every hour, decreasing as improvement occurs.

—SCHOULL.

Painless Blister.—

℞ Mentholis,	
Chloralis	āā gr. xx.
Ol. theobrom	ʒ ss.
Spermaceti	ʒ i.

M. ft. past. S. Apply.

A General Antidote for Poisons.—Borate of sodium mixed with milk is said to be the best general antidote after the stomach has been emptied. For vegetable poisons permanganate of potassium in one-percent. solution. For carbolic acid, vinegar. This is said to act well also externally.

Acute Alcoholic Delirium.—

℞ Chloralamid.	gr. xv.
Hyoscin. hydrobrom.	gr. $\frac{1}{100}$

M. S. Also useful in acute alcoholic mania.

—D. R. BROWER.

Vomiting in Phthisis.—

℞ Cocaine	0.25 cgm.
Elix. cinchonæ	20 gm.
Aquæ	150 "

M. S. Dessertspoonful every two hours.

—BARIÉ.

Or—

℞ Menthol	1 gm.
Spt. vini gal	20 "
Syr. simp.	30 "

M. S. Dessertspoonful in a little water every hour.

—LICHTENSTEIN.

Seborrhœal Eczema.—

℞ Sulph. præcip	10 gm.
Spt. camphoræ	10 "
Aquæ	250 "

M. S. Apply.

—HILLAIRET.

Bronchitis.—

℞ Terpinol,	
Sodii benzoatis	āā gr. ij.
Sacch. alb.	q.s.

Ut ft. pil. No. i. S. Six to twelve daily.

Arthritis.—

℞ Ext. hyoscyami	gr. xv.
Iodoformi	gr. xxx.
Sodii salicylat.	ʒ iss.
Petrolat	ad ℥ v.

M. S. Apply externally.

—*Therapist.*

Goitre.—

℞ Zinci sulphat.,	
Ac. salicylici.	
Iodoformi.	āā ʒ ij.
Ac. boric	ʒ iij.
Ac. oleic	℥ viij.

Keep at boiling heat for several hours, pour off the liquid, and bottle when cold. Apply by friction twice daily until slight desquamation occurs; after this once daily.—CHARETTE.

Anæsthesia of Urethra.—

℞ Cocæ	1
Aquæ	10

M. S. Apply.

—HERMAN.

Bromoform Syrup.—

℞ Bromoform	♏ xl.
Tinct. aconit	♏ l.
Syr. codein	ʒ iss.
Syr. tolu,	
Syr. rhœad	āā ʒ ivss.
Spt. vini rect	ʒ iiss.

M. S. Graduate dose according to age in pertussis, pneumonia, and bronchitis after measles.

—*Med. and Surg. Bull.*

Hemorrhoids.—

℞ Tinct. camph. comp	℥ i.
Camphoræ.	ʒ i.
Ung. bellad.	℥ xv.

M. S. Apply.

—NEHIGAN.

Palatable Effervescing Quinine.—

℞ Quinin. sulphat..	4
Acid. citric	10
Syr. simplicis,	
Syr. aurantii cort.	āā 1
Aquæ destillat	q.s. ad 20

M. S. Add ten or more drops to 50 gm. of water containing 30 cgm. of bicarbonate of sodium.

—*Therapist.*

Influenza.—In twenty cases treated by A. Claus there was remarkable amelioration of pain, fever, etc., after from two to four half-grain doses of salophen.

Succus Cinerariæ Maritimæ is said to act in the absorption of cataract when dropped into the eye daily, two or three drops at a sitting. The editor of *Experience* says of it, that in many instances the results are "nothing short of miraculous."

Permanganate of Potash in Dysentery is recommended in the form of injections by Gastinal, who gives to adults about 500 c.c. of a solution equal to 0.5 gm. to the litre and at a temperature of 45° R. For children 0.2 gm. and for very young children 0.1 gm. to the litre is recommended. The injections, which are to be retained from one-half to two minutes, must be given slowly; being preceded by a cleansing enema and followed by an hour's rest in bed. Their action is both astringent and antiseptic. Excellent results are said to be also obtained in proctitis.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

CLOSING CENTURY OF COLLEGE OF SURGEONS—BRADSHAW LECTURE—ARCHIVES OF NEUROLOGY—THE WAR—THE SCIENTIFIC BRANCHES OF THE ARMY—SMALLPOX AT HULL—DEATHS OF VETERANS—DEATH OF SIR JAMES PAGET—THE CINEMATOGRAPH IN TEACHING OPERATIVE SURGERY—NEW YEAR'S HONORS—A LIVINGSTONE EXHIBITION—"LANCET" RELIEF FUND—INFLUENZA.

London, December 29, 1899.

The closing year marks the close of a century since the Royal College of Surgeons received its first charter in 1800. Mr. H. G. Howse, who is the senior vice-president, delivered the Bradshaw lecture at the college on the 13th inst., and marked the occasion by taking for his subject "A Review of Surgery during the Past One Hundred Years." But it was a large order, and could not be executed in a single lecture except in the form of a few samples. So Mr. Howse discoursed of amputations and epidemics, leaving a host of other subjects untouched. Most of the time was, in fact, devoted to infectious diseases (anthrax, typhus, typhoid, diphtheria), as the lecturer thought that in this direction there is the most hope of advance in the immediate future. In some of these diseases advance has been made by methods which differ in different cases, and which are most likely susceptible of further improvement. But in most zymotic diseases we still are searching for clear, easily applied diagnostic tests. The need of such a test for tetanus was illustrated by reference to Larrey's memoir, in which cases were included among his illustrations which evidently were not tetanus at all. This was for want of a definite test, for which we are still searching and which the new century may give us.

While admiring the great advances of the last one hundred years and hoping for similar progress in the next, encouraging our bacteriologists and pathologists to persevere in their investigations, Mr. Howse concluded with a word of warning on the tendency to conclude too much from a single instance. Errors in this direction will produce more serious errors in the future. We are too apt to be dogmatic in our views which further knowledge may oblige us to modify. Nowhere is this more strikingly shown than in the rapid changes of antiseptic and aseptic details in the treatment of wounds. "It may reasonably be doubted how far some of these are really scientific and how far they are mere fads." Mr. Howse clenched this remark by quoting a saying of the late Master of Trinity: "We are none of us infallible; no, not even the youngest of us."

The day after his lecture Mr. Howse, as vice-president, took the chair at the council of the college in the absence of the president. At this meeting he received a formal vote of thanks for the lecture and was requested to print it. The council further agreed upon its usual *non possumus* in reference to the resolutions carried at the annual meeting of fellows and members. The council also considered the great clothes question, settled how much narrower the crimson facings of the member's gown must be than those on that of the fellows, and gave the tailor a good advertisement. It is really very amusing to see these eminent surgeons discussing the cut of a gown; but they went one better than this and formally resolved that "members who are graduates of universities shall be entitled, if they please to do so to wear their university gown on the occasions on which the member's gown may be worn." I cannot tell you which of the councillors originated this ridiculous resolution. He may pride himself on the success of his joke, but it seems rather hard to reduce the proceedings of the council below the level of broad farce. The council having assumed the right to authorize gowns for fellows and members, now seems to arrogate to itself the further authority to tell graduates of the universities when they will be graciously permitted to wear their legally authorized gowns.

If any of your readers desire to follow up my account of the late debate on tabes and general paralysis of the insane, they will find material for further study in the "Archives of Neurology from the Pathological Laboratory of the London County Council." This work extends to five hundred and fifty pages and has many illustrations. It is edited by Dr. F. W. Mott, F.R.S., who opened the debate at the Pathological Society, and is issued by the county council at 15*s*. It is to be followed by other volumes annually. You will remember that when the Claybury Asylum was built the county council determined to erect and fit up a first-rate laboratory for neurological research. This was done, and Dr. Mott was appointed director. A better appointment could not have been made, and the account of Dr. Mott's researches and those of his collaborators will interest all neurologists. These researches are original and well planned. They deal with questions that are surrounded with difficulties and doubt, eschewing the restatement of those which are settled. The questions relating to general paralysis, tabes, and syphilis are stated with clearness, and the investigations respecting them bulk largely in the "Archives." Other neurological researches are, however, reported, all of which are of the highest importance.

The war in South Africa is absorbing the attention of all classes, and already reputations seem to be ruined by the neglect and folly of some at the head of affairs. It is satisfactory to find that up to the present the medical department has come out of the trial with great credit, although it has been half starved by the War Office and reduced to such a dangerous degree that large numbers of civil surgeons have been hastily engaged for service both at home and abroad. Four additional consultants have also been engaged to go to the front, viz.: Sir William Stokes, surgeon to the Queen in Ireland, who sails to-morrow, and Mr. Kendal Franks, surgeon to the lord-lieutenant, and at one time resident in Johannesburg. These will well represent Irish surgery, so we may hope to hear no more of a grievance on the score of Dublin men being forgotten. From London, Messrs. Watson Cheyne and G. L. Cheatle, both of Kings College, will start shortly. Professor Ogston is also off to the Cape, but not on the government's behalf. He is going as an independent observer. You will remember his criticism at Plymouth on the way in which the army and navy medical departments are managed.

No fault can be found with the selection of the government if civil surgeons are to go. But what a reflection it is on the War Office and its boasted readiness! Nemesis seems on the track of Lord Wolseley. He has followed the evil example of his predecessor in starving the medical staff and insulting its members. Now at the first brush he has to acknowledge he must supplement it with civil surgeons—the civilians he has so much despised. That he blundered, too, in his estimate of the enemy's resources he has had to admit publicly. Now we are lamenting that he was allowed to abolish the chief office of artillery, and that against the opinion of every expert. So our guns are too few and too feeble. What has this to do with the medical department? Much in every way. The public cannot well understand the medical position, but the failure of the artillery is obvious and provokes a demand for immediate change of the system and removal of the man, whoever he may be, who is responsible. The commander-in-chief of course is the expert of the government; as such Lord Wolseley represented that everything was ready. He pooh-poohed all suggestions from those who know the country, and relied entirely on the infantry, despising, as he always has done, the scientific branches. His ineptitude is further manifested by the sight of his officers scouring the two hemispheres for horses, because he would not accept those on the spot; calling for volunteers because he fancies Cape horsemen are "mere civilians"; and snubbing the engineer, artillery, and medical departments out of sheer prejudice against scientific corps. Surely the revenge of these corps is at hand! But alas, the tragedies that are bringing it about!

The epidemic of smallpox at Hull has held its ground, and between seven hundred and eight hundred cases have been reported.

Death has been busy among our aged brethren. James Adams, of Aberdeen, died on the 20th inst., aged eighty-two years; J. F. Hodges, of Belfast, on the 13th, aged eighty-four years; R. H. Meade, of Bradford, aged eighty-five years, on the 23d; Andrew Spearing, of Belfast, aged seventy-four years, on the 17th; J. E. Brodie, of Glasgow; F. J. A. Waring, a retired surgeon in the Royal Navy, of Hove. These and other veterans have well served their generation and left their memory green where their lot was cast.

The death of William Cadge, of Norwich, was announced this week, but was afterward contradicted. He has been very ill with influenza, but I hear to-day there is hope of his recovery.

January 3, 1900.

Paget is dead. With these three words doctors greeted each other on Sunday, for the great and venerated surgeon died on Saturday night, "full of days and full of honors." For many years Sir James Paget occupied the foremost place in the profession and enjoyed the complete confidence and reverence of his brethren. He had retired for a long time from practice, but his personality was so distinct and his influence so unexhausted that he seemed to be still among us. His intellect was keen, his acquirements were numerous, his researches careful, and his judgment was well balanced. All his faculties were brought to bear on the case or subject under his notice, and his decisions were often regarded as almost infallible. Then outside professional topics his attainments secured the respect of all, and his views excited the greater interest by the felicitous way in which he expressed them. His essays could not fail to attract attention by their literary excellence, while they were full of instruction or well-sustained argument, often stated with remarkable force and charming eloquence.

Sir James Paget reached the age of eighty-five years. He was a Barts' student, and remained connected with that hospital all through his career. He took the membership of the College of Surgeons in 1835, and was, of course, one of the first batch of fellows when that order was instituted. In 1847 he was Arris and Gale professor; in 1865 he entered the council; was vice-president in 1873–4, and president in 1875. The next year he entered the General Medical Council, in which he represented the college until 1881. There is a fine bust of him by Boehm in the college, and his portrait, presented to Lady Paget in 1873, is in St. Bartholomew Hospital. Other colleges and societies offered him their highest honors, and universities did not lag behind. Thus the Dublin College made him an honorary fellow and the University M.D. Oxford, Cambridge, and Edinburgh presented their respective highest degrees. Of the London University, which grants no honorary degrees, he was for a considerable time vice-chancellor. Of societies it would be tedious to enumerate his distinctions; suffice it to mention the F.R.S. and the Paris Institute, with the presidency of more than one of the medical societies.

He was created a baronet in 1871, and appointed serjeant-surgeon to the Queen in 1877. He had long before been surgeon to the Prince of Wales. His "Lectures on Surgical Pathology," his "Clinical Lectures and Essays," and his "Studies of Old Case-Books" are classics as far as medical works can be classical, and no one can do better than look into either of them for an hour's delight and instruction. There are many other important contributions in St. Bartholomew's Reports, the Transactions of the Royal Society, and some of the medical societies. But these samples of his distinctions merely serve to show the esteem in which he was held as a surgeon and a scientist. They can only dimly suggest what he was as a man. Courteous, kindly, sagacious, genial, modest, his presence was ever welcome. A good talker, an eloquent lecturer, he charmed both young and old. As a surgeon, thoroughly informed and conscientiously careful, he was also possessed of that insight which so often looks like intuitive diagnostic power. His operative procedures were always steady, safe, and sure, and he never sought after the speed which some younger men call brilliant. His nature could not "appeal to the gallery."

Sir James leaves four sons—the eldest, John, of course, succeeds to the baronetcy; two are clergymen, and Stephen follows his father's profession and is already well known as a surgeon. Two daughters also survive him. The funeral took place yesterday. The first part of the service was held at Westminster Abbey and the actual interment at Finchley cemetery. Representatives of the many institutions with which he was connected were present; as some said, "everybody was there." The Queen, the Prince and Princess of Wales were also represented and sent wreaths.

You may perhaps remember that a good deal of interest was felt by some of those present at the Edinburgh meeting of the British Medical Association (1898) in a demonstration given by Dr. Doyen, of Paris, on the cinematograph. Some, indeed, were inclined to regard the exhibition as scarcely scientific, but others, knowing that M. Doyen was one of the foremost French surgeons, were well aware that he needed no clap-trap and was unlikely to bring forward anything that was not serious. Well, he has followed up his work with animated pictures and demonstrated their utility in teaching operative surgery. Dr. Doyen is not only an operating general surgeon, but also an eminent gynæcologist, and he has applied the cinematograph to that branch. At the invitation of the British Gynæcological Society he came over to London and gave a demonstration at their December meeting. The *modus operandi* in a number of operations was demonstrated by slides showing separately and consecutively the instruments required and the steps of the operation. This was followed by showing the operation complete as recorded by the cinematograph. In this way Dr. Doyen's ovariotomies, abdominal and vaginal hysterectomies, were exhibited in actual performance, to the evident delight of those present. A vote of thanks was proposed by Dr. Routh in a neat little French speech, and carried unanimously after complimentary remarks by Drs. Spanton, Godson, and MacNaughton Jones.

It would seem that the cinematograph has come to stay as a useful educational apparatus. Not a few, however, still regard it as a toy. But that was the case with the camera in time past, and yet what has photography accomplished for science! There may be a considerable rôle for the cinematograph.

The New Year's honor list is a short one, and so will disappoint many. Surgeon-General Lovell and Dr. Lauder Brunton are knighted. Dr. Cockburn, agent-general for South Australia, gets a K.C.M.G. Dr. Pringle, of the privy council of Jamaica, Dr. Patrick Manson and Dr. Wordsworth Poole, P.M.O., of the higher force, received a C.M.G. Dr. A. D. MacKinnon, of Uganda fame, receives the same order.

An interesting exhibition was opened on the 1st inst. by the Livingstone College. Many relics of the distinguished medical missionary and traveller were lent for the occasion, and there was a considerable collection of articles intended for travellers in unexplored regions. Major Ross discoursed on malaria and mosquitoes, and to-day Dr. Battersby is to lecture on "Health in the Tropics."

The eleventh annual report of *The Lancet* relief fund shows that £245 has been distributed to twenty-four practitioners who were suddenly in urgent need. This fund was established to help cases of real emergency, in which immediate aid would be likely to enable the recipient to tide over his difficulties. It is entirely supported by *The Lancet*. The sums granted this year ranged from £5 to £20.

Influenza is again taking a heavy toll in London, and many of the doctors are down with it. In November there were about fifteen deaths a week from it, but in December the number rapidly increased until in the week ending the 30th there were one hundred and seventy-three deaths registered from this disease. In the two preceding weeks the deaths were thirty-eight and sixty-nine. The increase is therefore great, and with it of course the epidemic is widespread, the non-fatal cases being very numerous. The deaths from all respiratory diseases last week were eleven hundred and seventy-two, above double the average.

THE APPENDICITIS QUESTION.

To the Editor of the Medical Record.

Sir: Allow me to add my humble mite of commendation of the remarks made by Dr. John Wyeth relating to the "appendicitis question," and published in a recent issue of your journal. Most heartily do I approve of what he advises in the treatment of abscesses occurring in connection with an inflamed appendix inaccessible to the gentlest and readiest manipulation.

It is very well for men like Dr. Morris and Dr. Deaver to practise and even publish "ideal surgery" respecting these cases. It is quite another thing for such operators to encourage and even demand such surgery at the hands of the general profession, in which, in these latter days, surgeons have multiplied with such amazing rapidity. Armed with a diploma and the certificate of an "up-to-date" post-graduate course in New York City, who will question the right, nay, the duty, of such men to undertake the most complicated operations in surgery? But do these legal authorities necessarily confer either natural or acquired surgical abilities? Rather do they not too often authorize and stimulate surgical temerity? Probably it would surprise Dr. Morris to know with what comparative infrequency an experienced and thoughtful surgeon is called in to operate for the average so-called country practitioner, who now considers himself lost in the race unless he has been to the cities, where he is imbued with the daring and enthusiasm of the great surgical pioneers. The results of the latter must be attempted, if not equalled, no matter what the cost.

Now if it be true that fifty thousand persons die annually in the United States from appendicitis, will Dr. Morris tell us, if he knows, how many succumb to reckless and indiscriminate operating? Notwithstanding increased facilities in the United States for learning surgery, how will Dr. Morris lessen this great mortality under existing conditions likely to be continued, so that his statistical assumptions, vehemently protested, will be taken at the value which he places upon them in support of the treatment that he advocates? Already, in this locality at least, the teaching of Drs. Morris, Deaver, and others is having the effect perhaps intended. Abscess cavities are opened and the deeply embedded appendix is laboriously and exhaustively sought after. If the limiting exudation wall is freely broken down by the manipulation, the post-mortem consolation to the family often runs like this: "I should have been called in earlier; the abscess had broken into the peritoneal cavity." Moreover, how annoying to an operator in an abscess case to be confronted with the reproach that he did not remove the appendix, when his neighbor, who had perhaps operated during the quiescent period, is able triumphantly to exhibit an appendix which, "following the surgical rule," he had skilfully removed! For the laity is not educated to make any distinction between these conditions, but rather the contrary. In the public view appendicitis is only appendicitis. Therefore the appendix must be removed at any hazard.

If it be a fact, as Dr. Wyeth avers, that in the vast majority of cases these abscess cavities soundly heal after proper opening and drainage, no further operation being required, is it not wise to inculcate his timely warning and advice? Certainly my experience strongly supports Dr. Wyeth in his contention. I have often questioned the feasibility of the advice of Dr. Deaver to antisepticize the abscess cavity and then safely to remove the appendix no matter how situated. In my last abscess case I am sure it would have been impossible to render thoroughly aseptic the pus-bearing area, including several minor pus cavities irregularly and remotely located in the septic exudation wall of the primal abscess. No amount of irrigation or wiping out with antiseptics would have accomplished this; and to break down the intervening trabeculæ would have been fraught with certain disaster to the patient. The abscess cavity was properly drained and granulated up, being now soundly healed. Judging from past experience I have little, if any, fear that a second operation will be required.

Henry K. Leake, M.D.

Dallas, Tex.

To the Editor of the Medical Record.

Sir: Allow me to make an analysis of Dr. Horner's defense of medical treatment of appendicitis, in the Medical Record for December 30, 1899, and comment upon some points that he makes.

Dr. Horner says he "believes that physicians can draw more practical conclusions from the means in their possession than the hospital surgeon with all his statistics. The general practitioners mingle with physicians of their own vicinity and have the benefit of one another's experience and observations." This is all very well, provided that the general practitioners are men of trained observation and accustomed to making accurate records of their cases in a scientific way. If the physicians in Dr. Horner's vicinity are men of this sort, I wish to have their reports upon appendicitis cases. I have tried for several years to get reports from physicians who had kept accurate records of their appendicitis cases, and have not been able to get such reports. On the other hand, the statistics are accurately kept in the best hospitals, and they are the very data upon which we must depend for our conclusions. The memory of one's experience, impressions, and observations is extremely treacherous unless one can turn to carefully recorded data; as I myself find in trying to quote at society meetings without the figures at hand.

Dr. Horner says: "It does not follow at all that appendicitis cases are alike because they are caused by bacterial infection, except it be in their etiology." I insist that they are alike in this respect, that no prognosis can be made of the extent of bacterial infection in any progressing case, and that the character of any given case is always determined afterward, never in advance. Cases which are found to have progressed to a complicated stage are complicated cases at the time when the surgeon is called to operate. The special reasons for the treacherous nature of appendicitis are fully described by authorities and need no further discussion.

Dr. Horner says: "If every one who has an appendix were to go to a surgeon and have it removed, and granting the surgeon the low mortality of one per cent., there would still be a great many deaths from the operation in cases without infection." Does the doctor know of any responsible surgeon who will operate for removal of the normal appendix?

The doctor further says: "That physicians are none too conscientious in refusing to advise operation in every primary case that comes along, will in my opinion be conceded by physicians and surgeons alike." Some of the most desperate cases with which we have to deal in everyday practice are primary cases that have been watched by physicians from the days when they were slight cases. The reasons for surprises have been fully described.

The doctor says: "The physician is always open to conviction, and if Dr. Morris can convince the general practitioner that his way is the right way and will save more lives than ours, we are prepared to follow, but not merely on his say-so." I have not always found that physicians were open to conviction. I have found that they were quite like other men in this respect; that men with trained minds had the habits of men with trained minds, that men who depended upon impressionist views preferred impressionist views, and that some preferred controversy for its own sake. The right way for saving lives does not depend upon my methods, but upon the classified knowledge of authorities which is accessible to all who read.

The doctor further says: "Dr. Morris asks us to tell him as to our cases, length of time wasted in bed, state of health after subsidence of acute attacks, and the state of the appendix as learned by accurate palpation. Let Dr. Morris also tell us of hernia pads worn for months after operations that do not relieve pain, of subsequent operations for adhesions; of operation for diseased appendix and removing an inflamed ovary which was the real cause of the trouble; of operation only to push the dislocated kidney back into position, of those who succumb to anæsthetics, of those whose kidneys and other internal organs have been damaged by the ether or chloroform, and of other little things we physicians consider before we send a perfectly healthy man who has had appendicitis once, and probably never will have it again, to be operated upon." Dr. Horner evidently has not closely witnessed the work of men who are successful in their operative work, or he would not quote the above list of casualties, which certainly do occur in the hands of men who have not properly equipped themselves for the management of these cases. Hernia pads should not be worn by patients of the surgeons in whom I have confidence. The days of post-operative hernia following appendicitis operations are about past. Subsequent operation for adhesions means that the physician did not give his case to the surgeon until it had become a complicated case. Operating for diseased appendix and removing an inflamed ovary which was the cause of the trouble means usually that the diagnostician did not use quite all of his resources before proceeding to assume a grave responsibility. Operating to push a displaced kidney back into position means carelessness usually, and if that was all that was done to the kidney the whole case was apparently mismanaged. As to patients succumbing to anæsthetics, I have never had that accident occur, either in appendicitis work or in any other department of surgery. Cases in which the kidneys or other internal organs have been damaged by the ether or chloroform were cases in which these organs had been previously damaged by some other cause, and in which they would presumably have been more damaged by the toxins of bacteria if the operation had not been done. Unless one has confidence in the ability of a surgeon to use judgment in these matters, he should make a study of surgeons as part of his duty toward the public. As to sending a perfectly healthy man to have operation done, the doctor would probably find it difficult to find a responsible surgeon who would operate upon such a patient.

I hope that the doctor will not find any spirit of discourtesy in my direct manner of statement. I have the highest regard for the good intention of physicians who, like Dr. Horner, are working for the best interest of their patients from their point of view. For the sake of progress it is important to have the point of view based upon our well-classified knowledge of the subject. We have abundant statistics showing the comparative results of medical and of surgical treatment in appendicitis. We know the reasons for these statistics. I have published the letters of a series of unselected consecutive appendicitis patients, all of whom stated that they suffered less under surgical treatment than under any form of medical treatment. If patients suffer less under proper surgical treatment, if the loss of time is less, if the death rate is less, the way is clear for physicians who Dr. Horner says are always open to conviction.

ROBERT T. MORRIS, M.D.

January 14, 1900.

THE TREATMENT OF PNEUMONIA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I have read with great interest the editorial in your issue of January 6, 1900, referring to the recent paper of Dr. A. H. Smith, of New York, on "The Treatment of Pneumonia in the Light of its Newer Pathology."

I agree with you in the doubt you express on the pathology of the pneumonia as outlined by Dr. Smith. As regards the treatment also I believe, as you do, that "if the toxic effects are greater than the body can combat, the patient must die; if not so great, the body will wage its own war, and the methods of treatment are but turns in the scale one way on the other."

Here I may repeat what I expressed in an article which appeared in *Sieroterapia*, Fascic. 7, 1899, that every physician had until now his own (empirical) treatment for pneumonia, and (I am translating) if the patient did not die, his recovery was due only to his natural constitutional strength and not to the ordinary treatment administered by the attending physician.

In the *New York Medical Journal* of August 26, 1899, was published a second article of mine on the same subject, in which, reporting six cases of the grave form of pneumonia cured with antipneumonic serum, I said: "There is a great deal of satisfaction in the knowledge that we now have a remedy which attacks the cause of the disease, and that it is no longer necessary to witness the progress of pneumonia with the feeling that we are powerless and can do nothing except try to stimulate the heart, to give expectorants, and to attempt to reduce the temperature by some antipyretic measure." Since then I have successfully treated nine additional cases by the same method.

Many well-known directors of clinics in Italy have used this serum with success, and many convincing laboratory experiments have been made by the Royal Academy of Medicine of Naples, as well as by Drs. Eyre and Washbourn at the Guy's Hospital laboratory in London. The last-named found (*Lancet*, April and October, 1899) that the serum possesses the potency claimed fcr it. One cubic centimetre protected a rabbit against three thousand fatal doses of living pneumococci, and they think they may affirm that in the future other successes will be obtained with the serum in the treatment of pneumonia in man, and in other affections produced by the pneumococcus.

I am really surprised that so eminent a physician as Dr. Smith, in his search for the best weapon against pneumonia, has not taken notice of the rational one. In the interests of humanity I hope that Dr. Smith will soon relegate to empiricism the creosote with which he has supplanted his remedies of yesterday.

Antonio Fanoni, M.D.

Society Reports.

NEW YORK MEDICO-SURGICAL SOCIETY.

Stated Meeting, January 12, 1900.

Egbert H. Grandin, M.D., President.

The Physiological Effects of Alcohol in Health and Disease.—Dr. Henry Ling Taylor read a paper with this title. He said that there were three principal views held regarding the effects of alcoholic beverages, viz., (1) The ignorant, (2) the biassed, and (3) the scientific. Belonging to the first class were those persons who seem to place no limit to the strengthening and healing virtues of alcohol, and who drink it when tired, weak, or sick, or indeed whenever there was even the slightest excuse for so doing. (The reader then passed around some of the text-books used for the purpose of compulsory instruction of children in the public schools regarding the alleged effects of alcohol.) Many of the statements quoted were astounding in their misrepresentations. Such teaching indicated the views of the biassed. According to the scientific view alcohol was powerless to prevent but temporarily allayed fatigue. In old age, and in certain conditions of debility, moderate indulgence in alcohol was beneficial. Alcohol should not be used by healthy people habitually as an appetizer. Mixed drinks and alcoholized tonics were much more harmful than pure spirits. Alcohol was often useful, sometimes indispensable, in pneumonia, typhoid fever, diphtheria, sepsis, and other serious acute diseases. It was a dangerous remedy in many nervous disorders, or if continued regularly for long periods. It was his opinion that alcohol was not so often or so frequently prescribed as formerly. It was thought that the practice of English hospitals of reporting the annual consumption of alcohol per capita might be profitably imitated in this country. Lord Roberts had stated recently that the admissions to the hospital in the British army were 208½ per thousand for abstainers and 301½ for non-abstainers. In conclusion, Dr. Taylor said that physicians should prescribe alcohol only when physiologically indicated; they should insist that the physiology taught in the public schools should not be a distorted physiology; they should discountenance the giving of alcoholic beverages to children except on a physician's prescription, and they should demand that the amount of alcohol contained in bitters and tonics be printed on the bottle.

Dr. H. H. Seabrook said that the physiological effects of alcohol in health were shown in the eye by the action on the blood-vessels. In chronic cases one frequently saw changes in the motor nerves, which might be peripheral or due to changes in the brain. These changes did not differ essentially from the changes occurring in other portions of the body. In the retinal and choroidal vessels there would be found arterial sclerosis in those who had taken alcohol for a long time. The special changes observed in the eye were those seen in the optic nerve of a chronic drunkard. The central fibres of the optic nerve underwent an inflammatory change, which was followed by atrophy, and which destroyed the central vision to a considerable extent. This change differed somewhat from the changes observed in other diseases. The change was similar to that observed in cases of poisoning from tobacco, iodoform, or bisulphide of carbon, and less intense than the change due to poisoning by lead. Certain changes were sometimes observed in the peripheral fibres. The ingestion of alcohol, therefore, when long continued seemed to act as a poison, though not as a virulent one. In slow forms of corneal ulceration stimulation of the heart and dilatation of the peripheral vessels resulting from the administration of alcohol was often most beneficial. The healing process in these cases was often exceedingly tedious, even under the use of the usual tonics; it was very materially hastened by taking alcohol. It was well known that syphilitics, and those using tobacco to excess, were most apt to exhibit the changes in the nerves already mentioned as a result of the use of alcohol.

Dr. S. E. Jelliffe said that one of the best arguments, to his mind, in favor of the good effects of alcohol was the almost universal use of it in all ages. He believed alcohol was a blessing, and when used in moderation in health conduced to that intimate social intercourse so necessary for one's success in life.

Dr. W. Gilman Thompson spoke more particularly regarding the use of alcohol in disease. It was well, he said, for physicians to ask themselves whether it was not possible to order less alcohol in the treatment of disease. Alcohol had some diuretic action in disease, but there were so many better diuretics that it certainly was not required for that purpose. In the majority of nervous disease alcohol was also not only uncalled for, but was positively injurious. On the other hand, there were conditions of nervous exhaustion and certain neuralgic affections which yielded well to alcohol. The effect of alcohol on the vascular system was the most important one for the therapeutist to consider. He was of the opinion that in a very large proportion of cases in which alcohol was used other and better remedies could be employed. Some years ago it had been customary to use much larger doses of alcohol in typhoid fever than now; the reason was found in the fact that its stimulating effect had been largely superseded by that secured by the judicious use of hydrotherapy. This former too liberal use of alcohol was certainly capable of developing a neuritis when the alcohol was administered for a considerable time in this fever, and it had seemed to him that there had been less neuritis since less alcohol had been given. In pneumonia alcohol was useful as a temporary stimulant. In alcoholic pneumonia it was certainly wrong to withhold alcohol, and so give an additional shock to the already depressed system. If, in such cases, the alcohol made the tongue moist, softened the pulse, aided respiration, reduced the temperature, and did not impart a strong odor to the breath within an hour or two after its ingestion, one might be sure that it was doing good. The habitual use of alcohol certainly tended, in a most insidious way, to excite premature degenerative changes. Some years ago he had been interested in collecting certain statistics from his hospital practice regarding alcoholic drinking. In his own division at Bellevue Hospital in the year 1898, there had been in all five hundred and six patients. Of this number there had been one hard drinker in every four, and only thirty-five total abstainers among three hundred and eighty men. Among one hundred and twenty-six women the proportion of hard drinkers had been one in sixteen. In examining these patients one was constantly struck with the large proportion of cases exhibiting arteriosclerosis. He had never been able to trace any case of alcoholism to the ordinary and temporary therapeutic use of alcohol in severe acute disease, and the same seemed to be true of the morphine habit, but it was an entirely different problem in chronic disorders when the patient continued for a long time to use alcohol or morphine without the physician's knowledge or consent. With regard to the use of alcohol in chronic disorders of the stomach, he was of the opinion that, as a general rule, it should be advised to leave alcohol alone. Late in life the moderate use of alcohol often prevented insomnia and added to the comfort of closing years. It was probable that many persons would become chronic alcoholics if it was not that they were blessed with bad stomachs, which did not allow them to become "full" without speedily getting empty again. In his opinion, alcohol was absolutely unnecessary for the preservation of health. The social side of this question was an entirely different matter. It was probable that the majority of persons would live longer if they did not use alcohol habitually, even in moderation. The use of alcohol could not be continued for long without lessening the resistance of the tissues and leading to more or less deleterious effects. Much depended upon constitutional peculiarities and general habits of life. Of course, alcohol should be distinctly prohibited to persons having a strong hereditary tendency to its excessive use. Finally, alcohol used properly for medicinal purposes undoubtedly saved life in acute diseases, as it constituted a valuable means of tiding over a crisis. In some of these cases he believed that alcohol acted not only as a cardiac stimulant, but as a true food.

Dr. William H. Porter said that when this question was considered from its standpoint as a food, one obtained a clearer conception of it. To his mind alcohol belonged to the same class of foodstuffs as starch, sugar, and fat. Assuming the natural intake of oxygen by the lungs to be 750 gm., by using 600 gm. of oxygen all of the starch, sugar, fat, and proteid matter could be burned that was required to generate the necessary amount of heat and keep up the constructive work of the body. This would leave 150 gm. of oxygen per day. Figured from a chemical basis this would allow nearly two ounces of clear alcohol to be burned without exceeding the oxygenating capacity of the system. He had been very much interested in the experiments of Professor Atwater at the government station, as they had demonstrated that this amount could be actually consumed in the body without overtaxing the oxygenating capacity of the system. It should be remembered, then, that this quantity could be burned in the system if its ingestion was properly distributed over the twenty-four hours. It had been pretty conclusively demonstrated by Anstie that alcohol did not enter the blood, as such, in any considerable quantity. Alcohol was very rapidly transformed into some other compound. It was his belief that alcohol was drawn up into the epithelial cells of the alimentary canal, and was there quickly oxidized, with the production of heat, carbon dioxide, and water. As a result, it had a tendency to overstimulate the nervous mechanism. This overstimulation was followed by depression, and unless the ingestion of the alcohol was evenly distributed over the twenty-four hours there must be inevitably an overstimulation. With this overstimulation there would be temporary contraction of the blood-vessels, thus interfering with the nutrition of the system. However, greater harm came from the use of alcohol by its disturbance of digestion, thereby exciting in the alimentary canal putrefaction, fermentation, and the formation of toxic products, and so indirectly affecting the system deleteriously. Physiologically speaking, there was no occasion for the use of alcohol in any individual in health until after the age of fifty or sixty years, and, in the majority of cases, its use before that time tended to cause derangement of digestion, and to affect the system injuriously through the absorption of the toxic products formed in the intestinal canal by the putrefactive fermentation of the proteid constituents. This opinion seemed to be strengthened by the position taken by insurance companies, who claim that beer-drinking people are the poorest risks. Such persons did not take in as much alcohol as spirit drinkers, but they eat more, and have more digestive derangement. He believed that in disease alcohol was very serviceable when the individual was unable to digest sufficient starch and sugar to yield the requisite amount of heat. In that sense alcohol might be looked upon as a food, though never as a good food. He quite agreed with Dr. Thompson in the assertion that more alcohol was given in disease than was needed. Assuming that typhoid-fever patients were able to take only one-half the usual amount of food, then such a person should not require over three ounces of alcohol in twenty-four hours. This would generate all of the necessary heat, and to go beyond this point meant only that the nervous system would be overstimulated, and that this would probably lead to neurotic conditions subsequently. He believed very positively that as people advanced in years and the digestive functions waned, the judicious use of a small amount of alcohol materially improved digestion and enabled such people to live longer and more comfortably than without this use of alcohol. This was especially true in cases in which the individual had not been accustomed to the use of alcohol. He believed that alcohol should never be given to the healthy individual under the age of fifty or sixty years, and that it should be used very cautiously in disease, the greatest care being taken that it did not cause disturbance of digestion. If this did occur, even in disease, then one might be sure that the alcohol was doing more harm than good. If the urea rose and the uric acid diminished under its utilization, then it was evident that the alcohol was doing good. With reference to the teaching of the effects of alcohol, Dr. Porter said that the more nearly the absolute truth could be brought before the youthful mind the greater the likelihood of doing good; in due time, the truth would come out in any event. He knew of a student who had been absolutely compelled to falsify his opinion on the physiological action of alcohol in order that his book might be brought before the schools.

Dr. Ernest W. Auzal quoted statistics collected by Jacquet and presented in a report recently made regarding alcoholism in the hospitals of Paris. The report had been based on a study of 4,744 cases seen in twenty-three hospitals. Of this number, 3,416 had been seen in the out-patient departments, and 1,328 among the in-patients. Of the former, 23.27 per cent. and of the latter 45.93 per cent. had been alcoholics. The drinks used chiefly were wines, liqueurs, and rum, but the use of absinthe was specially common. Of the 4,744, 217, or 4.57 per cent., had shown some disease dependent upon the alcoholic habit, such as gastritis, gastro-enteritis, various hepatic diseases, and paralyses. Of the whole number, 252 had advanced tuberculosis of the lungs, and of these 180, or 71.42 per cent., had been addicted to the use of alcohol before the first symptom of tuberculosis had made its appearance. The mortality had been greatest among those notoriously intemperate, such as liquor dealers, saloon-keepers, drivers, and cooks. Jacquet was of the opinion that physicians had unthinkingly contributed to the alcohol habit, as the annual consumption of alcohol in the Paris hospitals had doubled in the last twenty years. During the past year, however, there had been a marked decrease. He suggested that every patient leaving the hospital should be given a memorandum setting forth the dangers of alcohol. He also suggested that a permanent committee be appointed to consider this question of the effects of alcohol, and report annually.

Dr. E. Eliot Harris thought there was a proper use, as well as an abuse, of alcohol. He believed it was a valuable agent in relieving congestion of the internal organs, due to sudden chilling of the surface of the body. Alcohol relaxed the cutaneous arterioles, thereby retaining blood in the capillaries of the skin and adjacent tissues, and in this way it acted as a preventive of many diseases of the internal organs which followed what is popularly known as "taking cold." Alcohol had the power to bleed a man into himself, as it were, which made it a valuable agent in relieving embarrassment of the heart in pneumonia. There seemed to be a useful niche for alcohol in acute infectious diseases, in which its power as an antiseptic became manifest. When one considered the trouble arising from the abuse of so valuable an agent as alcohol, one could not but feel convinced that mankind, as a whole, would be benefited if it ceased to be manufactured.

Dr. McMurdy said that in hospital practice, in which tub baths were readily given, it might be easy to reduce the quantity of alcohol used in typhoid fever, but hydrotherapy was not applicable to tenement-house practice, in which alcohol must consequently be used freely. In diphtheria alcohol was often absolutely demanded, even though antitoxin was also used. He would not wish to practise medicine without alcohol.

Dr. J. Henry Fruitnight, in answering the question as to whether children in health should have alcohol, said that he would reply most emphatically "no." He would not dare to treat a severe broncho-pneumonia in a child without the administration of alcohol. He would be cautious about the use of alcohol in scarlatina because of the liability to nephritis. Years before the use of antitoxin excellent results in the treatment of bad septic cases of diphtheria had been secured by the free use of alcohol, and he still advocated its use in such cases, even if antitoxin was employed.

Dr. Theodore K. Tuthill expressed the opinion that alcohol was always a positive poison in health, and sooner or later its continued use must work to the injury of the individual.

Dr. William M. Leszynsky referred to the case of a child, aged five years, who had been brought to him at one time with an alcoholic multiple neuritis and paralysis, which soon terminated in death. The ignorant mother had thought she was doing a good thing for her little one by giving it regularly two bottles of beer and several drinks of whiskey daily. The speaker thought the text-books exhibited would prove useful, by impressing upon the older children the truth that alcohol was a poison and should be avoided.

Dr. Robert A. Murray spoke of the very common use by the laity of proprietary medicines containing a large percentage of alcohol. He believed such nostrums were often responsible for giving to individuals a taste for alcohol. He had never seen a case of acute disease treated with alcohol in which there had been any deleterious after-effects, except when the family had continued to give the patient during convalescence alcoholics instead of proper food.

Dr. Frederick Holme Wiggin said that with increasing experience he found himself depending less and less upon alcohol in the after-treatment of cases of abdominal surgery. His results had been much better by relying more on attention to digestion and the use of peptonized milk for nourishment than on alcoholic stimulation. As he believed shock was almost invariably due to hemorrhage, the best treatment was the introduction of saline solution either into the bowel or directly into the circulation.

Dr. A. E. Bieser spoke of the therapeutic efficacy of alcohol in septic conditions associated with various diseases, such as diphtheria, pneumonia, and typhoid fever. In these diseases alcohol seemed to fortify the cells so as to enable them to meet the demands made upon them by the invading bacteria.

Dr. E. H. Grandin said that he used much less alcohol now in septic conditions than he had done ten years ago, though he was free to confess that he still found it very useful in very low grades of sepsis. He agreed with Dr. Wiggin that shock was chiefly the result of hemorrhage, and therefore he relied upon the introduction of saline solution.

Dr. Taylor, in closing, read a letter from Prof. R. H. Chittenden, of Yale, expressing regret at his inability to be present, and stating that a recent investigation by Swedish chemists had fully established the results of Professor Atwater regarding the food value of alcohol. It was evident from the discussion, Dr. Taylor said, that the medical profession in this country used alcohol less than formerly, though clinging to it tenaciously to meet certain therapeutic indications. In this respect the habits of physicians here seemed to be in sharp contrast with those of the medical profession in Europe.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 18, 1900.

William H. Thomson, M.D., President.

Myocarditis.—Dr. John H. Musser, of Philadelphia, read a paper on this subject. He said that when the heart muscle was healthy few or no symptoms arose as the result of a valvulitis. The symptoms of myocarditis were intermingled with those due to other neural changes. A case was cited exemplifying the occurrence of myocarditis following, and secondary to, pericarditis. Myocarditis with dilatation was frequently seen as the terminal event in such lung diseases as emphysema. Myocarditis, both local and general, was often the result of coronary-artery disease. To the group of cases of myocarditis of toxic origin belonged the curious and puzzling cases of myocarditis associated with arrhythmia. In all forms of myocarditis there were certain common phenomena, particularly the sallow complexion of the individuals and the similarity of the physical signs. When this peculiar pallor was present one would not go wrong in assuming that the coronary arteries were implicated. These cases gave evidence of endarteritis in the vessels. The physical signs given by the heart were those of myocarditis alone, or of myocarditis plus hypertrophy or plus dilatation. The apex beat would be displaced to the left, and the cardiac dulness would be somewhat increased. Quite early there was "gallop rhythm," a cantering or reduplication of the systolic sound. It was more commonly heard about the fourth rib, and was sometimes more marked in the supine position, and usually more marked after exercise. Myocarditis was often overlooked in fevers because of the temporary disappearance of "gallop rhythm." Murmurs were not heard constantly until late in the disease unless complications were present. He believed, with Sewall, that the papillary muscles were the source of the auscultatory phenomena of myocarditis. It was not so much the presence of reduplication, or of gallop rhythm, or of murmurs, as the variability of the auscultatory phenomena which was so characteristic of this pathological condition. When dilatation supervened the physical signs changed in keeping with the physical condition of the heart. The terminal events of myocarditis varied; there might be apoplexy or ruptured aneurism, or renal phenomena. Again, there might be sudden and severe angina, or a gradual cardiac exhaustion lasting for a few days and terminating in œdema of the lung. In cases of myocarditis with angina, the attack might come on suddenly or be preceded by more or less dyspnœa. In the very large majority of the cases myocardial disease was present; whether it was causal or not he would not state. The course of these cases might be slow or rapid; one attack might terminate life, or the attacks might recur only at very long intervals. They might be preceded by a moderate amount of dyspnœa, and perhaps also by some arrhythmia. The pain was the predominating feature. Notwithstanding the temporary abatement of the symptoms the disease would progress, and eventually death would follow, and apparently from trifling causes. In some cases a slight change in the nutrition or general health would be sufficient markedly to affect the pain. In cases of myocarditis with dyspnœa, the latter might come on only after exertion, or when at rest, or perhaps only at night. In these patients the face was generally pale and anxious, and the forehead bathed in perspiration, the patient presenting all of the usual signs of profound shock. Examination of the heart would show its action to be rapid, feeble, intermittent, and irregular. Such an attack might at first occur at intervals of a year, but as the disease progressed this interval would be shortened. These attacks should be distinguished from those of acute dilatation of the heart occurring in certain cases of cardiac debility, because this was necessary in order to institute a proper treatment. This differentiation could be made, in a measure, by estimating the degree of cyanosis, and by a consideration of the fact that the signs in the lungs were those of œdema, in the case of heart failure, rather than congestion, while in cases of dilatation the phenomenon of congestion was the more prominent one. In cases of acute dilatation there was tachycardia, whereas in cases of œdema, with temporary arrest of ventricular action, the heart action was more apt to be slow. In the myocardial cases there was no congestion of the other organs, as for example the kidneys. In cases of dilatation, relief could be promptly afforded by venesection or by local blood-letting, whereas in myocarditis few physicians would care to resort to this procedure. The character of the breathing in myocarditis was very suggestive; the patient would speak to you for a short time, and would then have to rest in order to regain his breath. However, the frequency of respiration was not so great as that which attended dilatation of the heart. Cases of myocarditis presenting the so-called Stokes-Adams syndrome—pericarditis and pseudo-apoplexy—were very interesting to the clinician.

Myocarditis in Infants and Children.—DR. HENRY KOPLIK read this paper. He said that, in spite of the little space devoted in the text-books on diseases of children to the consideration of myocarditis, it was not at all rare, being a very common accompaniment of such acute infectious diseases as diphtheria, scarlatina, and typhoid fever. Romberg had called attention to the important fact that even in the severest cases all of the muscular fibres of the heart were not affected. Experimental research had made it probable that the myocarditis in these cases was the result both of the high temperature and of the toxins of the disease, and it was evident from clinical experience that high temperature alone was not responsible for its causation, as it was frequently found in rapidly fatal cases of pneumonia, for instance, in which the temperature had been low. In severe cases of pertussis, myocarditis would be found, partly as the result of the strain on the heart produced by the paroxysms of coughing, and partly as the result of the action of the toxins of the disease. While it was true that a most extensive myocarditis was often found at autopsy, in cases in which no symptoms referable to the heart were observed during life, there were many cases in which the feeble apex beat and heart sounds, with or without pallor and dyspnœa, should be sufficient at least to put the physician on his guard and cause him to suspect the presence of myocarditis.

Semeiology of Myocarditis is Complex.—DR. E. G. JANEWAY said, regarding the value of the facial expression as evidence of a myocarditis, that he could recall cases in which eminent clinicians had told the person during life that they had no heart disease, and yet the autopsy had shown extensive myocarditis. If there had been anything significant about the facial expression in these cases it certainly could not have escaped the notice of such acute and experienced clinical observers. Again, it was no unusual thing for angina to be mistaken for dyspepsia. This was largely owing to the proneness of attacks of angina to occur after partaking of a hearty meal.

DR. I. ADLER said that we could no longer divide sharply, as was formerly supposed, cases of myocarditis into two classes, viz., interstitial and parenchymatous. At a very early stage the muscle fibres underwent degeneration. In cases of simple atrophy or brown atrophy, in which the muscle became primarily affected and destroyed, the connective tissue underwent proliferation. He had never seen a specimen of myocarditis under the microscope in which both types had not been visible. Even in the most advanced cases of myocarditis the microscope would almost invariably show very many muscular fibres unaffected, and this might explain the apparent absence of cardiac symptoms during life. It was highly probable that the degree of the disturbance of the heart depended very largely upon the localization of the myocarditis. His clinical experience had led him to believe that in those cases of myocarditis characterized by œdema and dyspnœa the myocarditis was principally localized in the auricles. Arteriosclerosis was not by any means confined to the later years of life, and it was in these youthful cases of arterial disease that myocarditis was especially noted. This arterio-sclerosis was sometimes noticed shortly after puberty, chiefly in males. It was commonly the result of various toxæmias, the most notable of which was perhaps that resulting from the use of tobacco. Then there were cases of hereditary myocarditis without any toxic element, occurring almost wholly in young males.

DR. MUSSER closed the discussion. He said that he had not intended to convey the impression that the peculiar pallor alluded to by him was a constant sign, but only that when present it was very significant.

SECTION ON MEDICINE.

Stated Meeting, January 16, 1900.

JOHN H. HUDDLESTON, M.D., CHAIRMAN.

The Plague Bacillus.—DR. W. H. PARK gave a demonstration of the plague bacillus, the material having been obtained from two men sick with the disease on the steamer *Taylor* from Santos, Brazil. He had seen the men on the day of their arrival, and as they presented only an abscess of the lymph nodes in the groin they probably would not have been suspected of having the disease had it not been for the history of illness on board the ship. He had removed some of the pus from these abscesses, and had been much disappointed the following morning to find that there was no growth. After some difficulty he had succeeded in getting the culture. There was no difficulty in cultivating the bacillus when the material was obtained in the early stages of the disease. From what he knew now of the bacillus and its mode of growth, he felt that there should be no difficulty in the future in making the bacteriological diagnosis of the plague in the course of about twenty-four hours.

A Criticism of a New Method of Preparing the Skin for Vaccination by Denudation with Caustic Potash Solution.—DR. F. S. FIELDER read a paper on this subject (see page 143).

DR. S. F. MORRIS said that he had known nothing until this evening regarding this caustic-potash method of vàccination, and he could not see that it possessed any advantage, excepting in the one matter of not causing pain; but that should not be considered very seriously, for he was able to vaccinate a sleeping baby without awakening it. If caustic potash alone was applied to the skin, and no vaccine virus was rubbed in, the skin would probably closely simulate the ordinary vaccination scar. There was no such thing as "pitting" of vaccination. The large, hard cicatrix left by the present method of vaccination with bovine virus was entirely different from that formerly produced by the humanized virus. At that time the method in vogue had been to scrape off the superficial layer of the epidermis without drawing any blood whatever. In these cases the pitting seemed to be produced because the ulcer did not penetrate through the skin into the cellular tissue. With proper care scarification with the needle could be done in such a way that there would be no flow of blood unless pressure was made on the surrounding tissues. When the surface of the skin was denuded with caustic potash the serum was coagulated by the potash; hence, if great care was not taken to rub in the virus, it was probable that a much larger percentage of failures would result than had been noted by the reader of the paper. The speaker said that he had used almost every known method of vaccination that had been proposed and practised during the past thirty years. As a medical student he had been taught to make a little pocket with the lancet in the epidermis and introduce into this a "scab" when no liquid virus could be obtained. He had vaccinated many thousand children in the schools by using the lancet, but the great drawback to this method was the difficulty of properly cleansing the lancet when vaccinating such a large number of children. Subsequently he had found that the needle was far better than the lancet for such work. He had recently reported to the health department on fourteen hundred and sixty-five vaccinations performed with a certain lot of virus. Of this number there had been only one hundred failures, and a large number of these failures had been due entirely to the wilful removal of the virus by the colored children. These children had varied in ages from six to eighteen years, and the vaccinations therefore had been secondary ones, yet he had obtained, even under these adverse circumstances, over ninety per cent. of successes. This seemed to him an excellent showing for the method of needle scarification. He had never found it necessary to make any preliminary cleansing of the surface; he got no bad results except from the meddlesome after-treatment of ignorant mothers. Years ago, when he had been in the habit of scarifying a large area, he had sometimes seen erysipelas during the summer months, but never, even by this method, during the winter months. For this reason he ordinarily preferred to vaccinate in the winter time.

Œdema following Vaccination.—DR. W. H. PARK said that he had understood that Dr. Hutchins had claimed better results from the caustic-potash method, and he would like to ask Dr. Fielder if Dr. Hutchins had really made any careful comparative tests to substantiate such a claim. He would also call attention to the fact that in some individuals vaccination seemed to be followed by œdema of the whole upper extremity without any really septic condition being present. This œdema usually subsided in two or three days without anything more serious than a little inconvenience.

DR. FIELDER closed the discussion. He heartily agreed with Dr. Morris that there was no such thing as a characteristic vaccination scar. He had personally found it difficult to make an adequate scarification with the needle on a struggling child without drawing some blood. The health-board vaccinator who had secured the largest percentage of successes had made a practice of needling deeply and drawing blood, and then depended upon a very thorough rubbing in of the virus. He certainly believed if he had not taken great pains to rub in the virus after using the caustic potash there would have been many more failures. He had not understood that Dr. Hutchins had made any comparative tests. He did remember that Dr. Hutchins claimed to have had "only two failures in thirty-six primary vaccinations"; such a showing among primary vaccinations was not considered a good one at the present day among experienced vaccinators.

A Critical Study of the Justus Blood Test for Syphilis.—DR. D. H. JONES read this paper. The test depended upon the assertion that a single inunction of mercury, in all untreated cases of syphilis, caused a reduction in the hæmoglobin due to the sensitiveness of the red blood corpuscles to the action of this drug. Justus claimed that this reduction followed intravenous and subcutaneous injections of mercury as well as inunctions, but that no reaction was obtained if the mercury was administered by the mouth. Justus had reported on three hundred cases he had studied in this way. During the past six months, the speaker said, he had applied this test frequently in some of the hospitals in this city. The quantity of hæmoglobin had been determined by means of the specific gravity test of Hammerschlag. After having tested the quantity of hæmoglobin in this way, the patient was told to rub into the breast from gr. xx. to gr. lx. of mercurial ointment, and after an interval of from twenty-four to seventy-two hours the hæmoglobin was estimated again. The fifty-three cases were divided into thirty-five syphilitics and eighteen controls, and the thirty-five syphilitics were again divided into seventeen cases of active syphilis not under treatment, one under treatment, two latent cases, eight cases of chancre with adenitis, and seven cases of chancre without adenitis. Of the seventeen cases of syphilis not under treatment, thirteen had responded to this test. Of these thirteen twelve had had a macular or papular syphilide, and a history of chancre. They had been tested from three to ten weeks after its appearance. The remaining case had had a characteristic mucous patch on the inner side of the cheek, but no chancre could be found, and syphilitic infection had been denied. Nevertheless this case had improved with suspicious rapidity under mercurial treatment. Three of the four negative cases had been pronounced syphilitic by experienced diagnosticians. Of the eight cases of chancres with adenitis only two had reacted positively. The author concluded that the test had a positive value, yet it often failed in the latent cases of syphilis. Its range of usefulness had not yet been determined; like the diazo reaction in typhoid fever it had a certain positive, but no negative value.

Dr J. Ewing said that he had no criticism to offer regarding the methods employed, except as to the estimation of the hæmoglobin. Personally, he believed that the Fleischl hæmoglobinometer afforded a more accurate means than the specific-gravity method for the estimation of the hæmoglobin. The fact that the administration of mercury caused anæmia had been noted before it had been described by Justus, but this investigator had perhaps been the first to call attention to the fact that a recognizable anæmia might follow from a single dose of mercury. Justus believed that this anæmia was the result of an alteration of the serum, and also of the direct globulicidal action of the mercury itself. It had been shown that immediately after an inunction many of the cells containing a diminished quantity of hæmoglobin had been removed from the circulation; apparently, therefore, there was a reduction of the red cells immediately after the administration of a large dose of mercury. Such a result did not follow if small doses of mercury were used.

The Test Probably Operative in Other Diseases.—The question naturally arose here, Was this change in the blood specific, and characteristic of syphilis only? Personally, he thought there was reason to believe that such a change might be observed in many other diseases, notably in cases of malaria and in all forms of sepsis. There were certainly many cases in which there was a distinct increase in the globulicidal action of the serum, and here Justus' test would be likely to fail. Of the thirty-three cases which Cabot used as controls the hæmoglobin percentage had been between ninety-five and one hundred, except in two cases, and in these two the administration of the mercury had given a positive response, although the individuals were not distinctly anæmic. When there was no increased globulicidal activity of the serum from other causes than syphilis he thought it exceedingly probable that further investigation would show that Justus' test would respond.

Dr. B. Lapowski called attention to a later statement published by Justus in 1896, in which he admitted that his test could be made to respond even when the mercury was administered by the mouth in the form of pills. Justus' method of estimating the hæmoglobin had not been by the specific-gravity method, but by means of the Fleischl hæmatometer. Again, Justus had simply stated that the test was observed after the absorption of mercury—not that it occurred after a single dose of mercury. It did not necessarily follow that the mercury had been absorbed even if a single dose had been given. Moreover, Justus did not ordinarily employ a large but a medium dose of mercury, from 2 to 5 gm. of mercurial ointment.

Dr. Jones, in closing, said that in the article by Justus, published in 1897, the statement had been made that reduction of the hæmoglobin was observed only immediately after the inunction, and that the percentage increased ultimately. He agreed with Dr. Ewing that the specific-gravity method of estimating the hæmoglobin was somewhat crude.

Chronic Vertebral Rheumatism and its Pseudo-Neuralgic Form.—Dr. H. Forestier, of Aix-les-Bains, read this paper. He said that the chronic spondylitis observed by him had exhibited a temporary rigidity of the vertebral column without any ankylosis, pain radiating from the back to the loin and simulating in some cases tabes, and an affection of other joints pointing to its rheumatic nature. In most of the cases the posture and gait had been stiff, and there had been tenderness along the spine with more or less neuralgic pain. These patients had walked with the feet far apart, keeping the trunk immobile. A peculiar feature had been the backache occurring in the early morning, or when the patient had been lying down for a number of hours. As a rule, the knee jerk had been exaggerated, and in some cases there had been ankle clonus. There was no ankylosis of the spine in these cases; the immobilization was due to the pain. The dorsal and lumbar regions had been chiefly affected, the cases involving the cervical region being quite rare. The treatment had consisted in the application of sulphurous waters in the form of "a douche massage." The condition was to be differentiated chiefly from spinal irritation and external pachymeningitis of the spine.

Dr. V. P. Gibney said that he had been familiar with this class of vertebral rheumatism for the past fifteen years, his attention having been first called to it by a paper from one of the bath establishments in France. He had taken an additional interest in it because of the discussion that had occurred as to whether spondylitis was a hyperplasia or a caseous degeneration of the bodies of the vertebræ. To the orthopedic surgeon differential diagnosis was most important. Some of the clinical symptoms given in the paper this evening resembled those of disease of the bodies of the vertebræ. He was glad to hear of the good results obtained from the treatment. In this country massage and counter-irritation, douches, etc., were employed in conjunction with constitutional treatment and local support.

Dr. Forestier, in closing, said that a "douche massage" was given with the person in a sitting posture, a stream of water being directed forcibly against the different regions of the body while the parts were subjected to vigorous massage. The douche to the spine was most conveniently given while the patient was lying in the prone position on an inclined table. The douche massage is given in a stone chamber containing more or less steam, and the temperature of the water is regulated by the physician's prescription. A tremendous stream of water is discharged from a large nozzle with great force against the patient.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending January 20, 1899:

	Cases.	Deaths.
Tuberculosis	200	180
Typhoid fever	24	10
Scarlet fever	245	13
Measles	777	28
Diphtheria	287	41
Laryngeal diphtheria (croup)	10	11
Cerebro-spinal meningitis	0	4
Chicken-pox	33	0
Smallpox	1	0

Clean Paris.—An English weekly journal says that Paris is probably the cleanest city in the world. Every morning two thousand male and six hundred female scavengers, divided into one hundred and forty-nine brigades, turn out to perform the toilet of the capital. The men work from four in the morning till four in the afternoon, less two hours off for meals, or ten hours a day. The women are engaged in the morning only.

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended January 19, 1900:

		Cases.	Deaths.
SMALLPOX—UNITED STATES.			
Delaware, Wilmington	January 6th to 13th	..	1
Florida, Jacksonville	January 6th to 13th	2	
Georgia, Jessup	January 16th	1	
Illinois, Cairo	January 1st to 7th	5	2
Chicago	January 6th to 13th	4	
Louisiana, New Orleans	January 6th to 13th	13	2

Portugal, Lisbon	January 1st	1	
Masau	December 25th	9	7

Congenital Hypertrophy of the Pylorus in an Infant.—Batten (*Lancet*, December 2, 1899, p. 1511) reports the case of a male infant, eleven weeks old, who at the age of five weeks had begun to vomit, while at the same time the bowels became very costive, and wasting set in. The food was ejected in from five to ten minutes after feeding. The child had been fed by the breast until the age of nine weeks, and was then tried on cow's milk, but as this did not agree he was given Nestlé's food. The child was thin, and weighed seven and a quarter pounds. The abdomen was flaccid, and easily palpated without pain. On inspection the peristaltic movements of the stomach could be seen distinctly passing from left to right, and following one another in quick succession. On deep palpation in the right hypochondrium, about a finger's breadth outside the nipple line, a firm transverse mass, in shape like the pylorus, could be felt, but which was not always palpable when no peristalsis was taking place. The child was at first fed on equal parts of cow's milk and barley-water, but the vomiting persisted. He was then given two ounces of cow's milk and one ounce of barley-water through a nasal tube every two and a half hours. During the succeeding few days, although the vomiting did not entirely cease, the child improved and passed a digested stool. He improved in appearance, and the vomiting became less. Subsequently a teaspoonful of cream was added to the nasal feeding, and then some cod-liver oil. Eight ounces in weight were gained in two weeks. An attempt to resume feeding by the mouth was followed by repeated vomiting, so that nasal feeding was again resorted to. The pylorus had become less distinctly appreciable than it had been, and at times could not be felt at all. Subsequently the child was applied to the breast, and although the vomiting returned it eventually ceased. The possibility of operative relief was considered, but owing to the feeble and wasted condition of the child it was at the time deemed inadvisable. Steady improvement, however, took place, so that in the course of six months the weight had increased to sixteen pounds. The child was now seized with a fatal broncho-pneumonia. On post-mortem examination the walls of the stomach were found to be unusually thick, and the pylorus was firm and hard. On microscopical examination the mucous membrane and the muscular coat appeared to be perfectly normal in structure, while the circular coat was considerably thicker than normal.

Books Received.

While the MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

THE SIGNIFICANCE OF INTRA-OCULAR HEMORRHAGE AS TO PROGNOSIS OF LIFE.

By CHARLES STEDMAN BULL, M.D.

NEW YORK.

It is a well-known and generally recognized fact that certain diseased conditions of the blood and of the blood-vessels cause certain lesions in the interior of the eye. From the standpoint of the clinician a careful study of these changes is of great importance, because they not only affect the vision, but because they are frequently of significance in judging of the general health of the patient.

Close observation of the retinal circulation and blood-vessels affords a certain amount of definite information in regard to the condition of the blood-current and blood-vessels throughout the body, especially of those of the brain, and to a minor degree of the heart and aorta. We know that the intraocular circulation is subject to influences and conditions similar to those which prevail in the general systemic circulation. An increased supply of blood to the brain cannot well occur without a similar increase in the eye, and the same may be claimed also for the anæmic condition resulting from a weakened force of the heart's action or from the diminished volume of the blood. One fact which is not generally recognized may here be mentioned, and that is, that the eye is relatively but sparingly supplied with blood, as a very large part of the blood going to the region of the eye from the external and internal carotid arteries is distributed to the eyelids and orbit. Hence it follows that a hyperæmic or anæmic condition of the parts, occasioned by changes in the calibre of the vessels, will be induced more easily the nearer to the eye the vascular disturbance occurs. If the cause is remote, acute congestion of the blood-vessels is rarely accompanied by retinal hemorrhage with resulting damage to vision. It may be stated that the cause of the intra-ocular hyperæmia being remote from the eye, hemorrhagic extravasations rarely occur if the blood-vessels are healthy. If this were not so, we should meet with retinal hemorrhages in violent paroxysms of cough or in epileptic convulsions, as frequently as we do with subconjunctival hemorrhages.

In obstruction of the trunk of the central retinal artery, the changes in the blood-current marked by a breaking up of the column of blood in arteries and veins, with venous pulsation, are of transient duration, and frequently are followed by increased fulness of the vessels with the appearance of hemorrhages. When the vessels remain contracted, hemorrhages rarely occur, or, when they do, not until a number of days after the onset of the trouble. One interesting fact, to which Haab has called attention, is that when the obstruction is in a branch of the central retinal artery and not in the main trunk, hemorrhages in the retina almost never occur.

When the case is one of thrombosis of the central retinal vein, hemorrhages into the retina are certain to occur, and sometimes even subhyaloid extravasations are found. In this condition general albuminuria is very frequent and leads to a grave prognosis. Hence in all cases of thrombosis of the central vein or of any of its branches, the urine should be carefully analyzed. Experience has taught us that if the patient is young the condition is apt to be connected with constitutional syphilis.

In senile angiosclerosis, marked by thickening in the coats of the vessels, with marked differences in the calibre of the vessels at different points, one of the commonest symptoms is retinal hemorrhages, which resemble those met with in thrombosis of a venous branch. This is an important symptom and signifies marked degeneration of the vascular walls. In this condition we also meet with hemorrhages between retina and choroid, between retina and vitreous, into the vitreous, and very frequently with subconjunctival hemorrhages. Attention is here called to the fact that the more carefully these patients are examined for syphilis and albuminuria, the more rarely do we meet with cases of real senile retinal hemorrhages, for syphilis produces changes in the vessels very similar to those met with in senile angiosclerosis. In this connection it should not be forgotten that arteriosclerosis with accompanying hemorrhage is very closely related to glaucoma.

The recurrent hemorrhages, not infrequently met with in young persons, are due to this degeneration of the vascular coats. They may be of any shape, but are more apt to be crescentic. They are usually subhyaloid, between the retina and vitreous, and the prognosis is good, the number of relapses not influencing materially the ultimate result. If, however, the extravasation is extensive and in the vitreous, the prognosis is grave, especially if there is a history of recurring epistaxis; for in these cases of vitreous hemorrhage the blood comes from the peripheral vessels and indicates disease of the choroidal vessels as well.

In all these cases of intra-ocular hemorrhage in the young the fundamental disease is an affection of the vessel-walls of a really unknown nature, which causes an abnormal brittleness of the coats. Inherited syphilis is probably influential in the production of the lesion. The prognosis as to the integrity of the eye is always doubtful. If the hemorrhages are in the retina, or between the retina and the vitreous, they are less serious than if they occur in the vitreous, and if inherited syphilis is present the prognosis is more favorable.

We have the authority of Gowers for the statement that passive congestion of the retinal vessels, or venous hyperæmia, with or without hemorrhages, accompanies cardiac lesions in which the return of the blood toward the heart is impeded, as in disease of the mitral valves and in fatty heart, and that the retinal hyperæmia is part of a cephalic congestion. If pulsation of the retinal arteries is also present, there is general aortic insufficiency. In mitral disease there is also hypertrophy of the left ventricle, so that the blood pressure is increased during its contraction and the venous hyperæmia results from the regurgitation which accompanies the ventricular diastole.

Simple retinal hemorrhage without retinitis indicates an increased blood pressure, or disease of the vessel walls, or a morbid condition of the blood, and sometimes all three conditions.

Gowers also states emphatically that the existence of angiosclerosis in the retina is a positive indication of a similar condition existing in the vessels of the brain, and that when accompanied by retinal hemorrhage it is a warning signal of impending cerebral apoplexy, especially when accompanied by high arterial tension.

One of the rare ophthalmic lesions is embolism of the central retinal artery or of one of its branches, and this is sometimes accompanied by hemorrhages into the retina. This has been known to be the first indication of an insidious endocarditis.

The same vascular changes are very frequently encountered in chronic nephritis and in diabetes. The tendency to hemorrhage which exists in so marked a degree in many cases of nephritis leads to extravasations in the retina. They are mainly in the nerve-fibre layer, are striated or flame-shaped, and follow the course of the vessels. They are of grave prognostic significance, and independently of the typical signs of retinitis albuminurica point to a not far distant fatal termination of the disease.

In diabetes the retinal hemorrhages appear as small rounded spots. They always occur if the disease has lasted a number of years, and are of unfavorable prognostic significance. The association of nephritis with the later stages of diabetes should not be forgotten, as well as the possibility of the dependence of the retinal hemorrhages on the latter disease, though here the hemorrhages are generally striated.

Dr. Herter, of this city, has made an interesting suggestion with reference to general arterial sclerosis, which may have a bearing upon the causation of certain cases of retinal hemorrhage in which the origin seems obscure. He states that in rare instances a general arteriosclerosis has its beginning in a series of acute seizures of gastro-enteritis, which leave behind them marked impairment of intestinal digestion. When this occurs in persons under twenty-five years of age, there can be little question that the gastro-enteritis stands in a causal relation to the alterations in the vessels and similar changes in the kidneys.

Germane to this suggestion are the remarks of Mr. Marcus Gunn before the Ophthalmological Society of the United Kingdom in 1898. In speaking of general arterial disease, he says: "In many of these patients the primary cause is probably a form of poisoning due to indigestion, a mal-assimilation and imperfect elimination producing disordered nutrition, and the blood-vessels suffer in consequence. Chronic alcoholism is undoubtedly a strong factor in causing this affection, for old age alone does not produce these changes. While confined to the arteries hemorrhages are very infrequent, but as the condition extends to the capillaries and veins hemorrhages are the natural result."

In many anæmic conditions there is a state of diminished blood-pressure which, after prolonged duration, leads to spontaneous retinal hemorrhage. In cases of blindness after sudden and great loss of blood the blood-pressure falls materially, and the elastic intra-ocular pressure forms an obstruction to the circulation in the retina, and as a result retinal hemorrhages are frequent. The loss of sight is here probably due to a hemorrhage within the optic nerve. With returning circulation vision is sometimes partially restored, and then occur the retinal hemorrhages.

Retinal hemorrhages due to a diseased condition of the blood occur in infectious diseases, in pyæmia and septicæmia, in profound pernicious anæmia, in malaria, and in cases of poisoning. While the diagnosis of infectious diseases is not dependent on the existence of retinal hemorrhages, they are frequent occurrences and of prognostic importance. They may occur at all stages and form an unfavorable complication, especially when found early in the disease; they indicate a condition of profound toxæmia. When hemorrhages occur early in acute septicæmia, a fatal termination may be expected in a few days.

The presence of retinal hemorrhages affords valuable evidence in the differential diagnosis between chlorosis and pernicious anæmia, for they are frequent in the latter and never occur in the former. An interesting diagnostic fact is that retinal hemorrhages rarely occur in the cachectic conditions resembling anæmia.

In 1886, in a paper read before the American Ophthalmological Society, I called attention to cases of intra-ocular hemorrhage occurring in persons of middle and advanced life who had been subjected to severe malarial poisoning, and my interest in the subject was revived during the summer of 1898 and 1899 by the number of such cases seen in our troops returning from Cuba. In these cases the blood was extravasated into the vitreous humor and occasionally in the aqueous humor, and was entirely unaccompanied by any sign of intra-ocular inflammation. The hemorrhages always occur suddenly and usually in the posterior part of the vitreous humor. They are generally unilateral, though they may be found in both eyes, and they appear during the febrile or congestive stage. The recurrences of these hemorrhages are spontaneous and frequent, and the process of absorption is always slow. They indicate a condition of profound malarial toxæmia, and the prognosis as to life is decidedly unfavorable.

In a paper read before this society in 1897 attention was called to the occurrence of retinal hemorrhages in typhoid fever, with reference to the stage at which they occurred and their prognostic significance.

In progressive pernicious anæmia the tendency to retinal hemorrhage is very marked. The extravasations are numerous, are striated or flame-shaped, and are most abundant round the optic nerve. The small ones may be absorbed, but the large ones remain and point to an unfavorable termination of the case.

In leucocythæmia retinal hemorrhages are almost an invariable symptom. They are widely scattered in the nerve-fibre layer and are of no particular significance. But if they occur in the optic nerve or vitreous their prognostic significance is unfavorable.

In purpura small retinal hemorrhages are of common occurrence, but more rarely they are subretinal and are then significant of a severe type of the disease.

In jaundice retinal hemorrhages are not common, and when met with they indicate a severe type of disease.

In all hepatic diseases small retinal hemorrhages are common, especially in cirrhosis, and are of no special importance. But in the severe types of cirrhosis and acute atrophy of the liver, large hemorrhages between retina and vitreous or in the vitreous are occasionally discovered, and their prognostic significance is most unfavorable.

Summarizing what has preceded, the following conclusions may be drawn from our experience:

1. Hemorrhages into and beneath the conjunctiva are of little importance in the young, as they usually occur as a result of violent muscular effort, as in coughing or long-continued sneezing. The vessels in the conjunctiva, having little or no support in the loose connective tissue, readily give way to paroxysms of violent expiration. In the aged they occur spontaneously and point to a general weakened condition of the vascular walls.

2. Hemorrhages in the interior of the eye are always of prognostic significance. In senile angiosclerosis

retinal hemorrhages are very frequent, and point significantly to the probable occurrence of cerebral apoplexy.

3. Recurrent retinal and subhyaloid hemorrhages in the young are of slight prognostic importance, especially if due to syphilis, whether inherited or acquired.

4. Hemorrhages into the vitreous in the young are of grave prognostic importance and point to the existence of general vascular degeneration.

5. In chronic interstitial nephritis and in diabetes retinal hemorrhages are of very grave prognostic significance, and independently of the presence of exudative retinitis point to a fatal termination of the disease. The mere presence of thrombosis of the central retinal vein with hemorrhages in the retina should arouse suspicion of the existence of albuminuria, and if this suspicion is confirmed by urinary analysis the prognosis in the case is more unfavorable than in those cases in which the hemorrhages do not exist.

GASTRECTOMY FOR ADENO-CARCINOMA; RECOVERY.

By H. BEECKMAN DELATOUR, M.D.,

SURGEON TO THE NORWEGIAN, LONG ISLAND COLLEGE, AND ST. JOHN'S HOSPITALS, BROOKLYN.

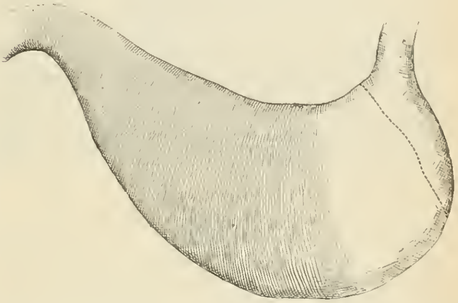
Since Schlatter, of Zurich, proved, by his successful case in 1895, that it was possible for a person to live after complete removal of the stomach, a number of operators have followed his example. It is only in those cases in which the growth is entirely limited to the stomach that gastrectomy is permissible, for in these it offers a chance for permanent cure.

The general indications and contraindications for the operation have so recently been considered by Richardson[1] that it seems hardly necessary to review them here. It is my desire in reporting this case to assist in developing the statistics of this procedure, and to add the following to the reported cases of gastrectomy:

Mrs. S——, aged twenty-six years, Norwegian, housewife, was admitted to the Norwegian Hospital, giving the following history: She became pregnant about a year before we saw her. Previous to this she had suffered with symptoms of dyspepsia, distress, vomiting, etc., but during pregnancy these became much more distressing and constant, and persisted even after the termination of pregnancy. During the three months intervening between labor and her admission to the hospital the vomiting continued, becoming more and more frequent, until finally all food was rejected within a few hours. Pain began and became more and more intense; there was a rapid loss of strength, and her weight had fallen from one hundred and forty pounds to ninety pounds. Examination revealed a tumor, visible to the eye, along the margin of the left costal cartilage; by palpation this could easily be located as at the pylorus.

On May 2, 1898, under ether anæsthesia, a four-inch incision was made, beginning one inch below the ensiform cartilage. The tumor was found to occupy and to be limited to the pylorus and stomach, and to be freely movable. It was my intention to do a gastroenterostomy, but the case seemed so favorable for complete removal of the disease that gastrectomy was decided on. The mass was dragged well into the wound and the omentum tied along the greater curvature with catgut sutures one-half inch apart. Then with scissors this edge of the stomach was cut free. With the fingers behind the stomach so as to direct the ligature carrier, the margin of the lesser curvature was freed in the same manner. Now the stomach was free from the duodenum to the œsophagus. A clamp was next applied to the duodenum, and the intestine was cut across one inch from the pylorus. The field of operation was carefully protected with gauze sponges before the œsophageal incision was made, and this was fortunate, for considerable fluid escaped from the dilated stomach. The entire pylorus, the whole length of the lesser curvature, and nearly the entire cardiac end of the stomach were removed, the incision extending well into the wall of the œsophagus (see diagram). This left the œsophageal opening somewhat larger than the duodenal, so a few silk sutures in double layer were used to reduce this opening. The duodenum was then sutured into the œsophageal opening with fine silk sutures. Thorough cleansing of the field of operation, a small strip of iodoform gauze introduced, and closure of the wound completed the operation. The time required for the operation was fifty minutes.

The patient reacted well, and on the following day had the highest temperature of her convalescence, 99° F. The pulse was 120. Rectal feeding was maintained for seven days. The nourishment consisted of peptonized milk and other predigested foods, the bowel being washed once in twenty-four hours. The gauze packing was removed on the fifth day, and as there was no discharge was not replaced. At the end of the week, feeding by mouth was commenced with one ounce of peptonized milk every two hours. As the patient bore this well it was rapidly increased and other articles of food added, so that at the time of her discharge from the hospital on June 5th she was taking the ordinary mixed diet.



The shaded portion represents the new growth; the broken line the section. At the pylorus the growth measured about one and one-half inches in thickness.

The only unpleasant feature of convalescence was hunger. Before operation the patient had begun to hate the sight of food, but within the first week after removal of the disease it was almost impossible to prevent her being fed by other patients, on the sly, so piteous were her pleadings.

After the patient left the hospital her condition continued to improve, so that at the end of six months she had gained thirty pounds. About six months ago she came to me complaining of nausea, but no vomiting. Examination revealed no evidence of a return of the disease. The cause of this nausea I discovered in September, when I visited her to ascertain her condition, over seventeen months having elapsed since the operation. At this visit I found her tending her two children, looking perfectly well and strong and seven months pregnant. Since then she has removed from Brooklyn, and I do not know what the termination of the pregnancy has been, nor what her general condition is.

In May, 1898, the specimen was presented to the Brooklyn Surgical Society, and in the following October the patient was presented. The growth was examined by Drs. J. M. Van Cott and A. Murray, and pronounced an adeno-carcinoma.

---

73 Eighth Avenue.

REPORT OF A SEVERE X-RAY INJURY.

By PATRICK CASSIDY, M.D.,

VISITING SURGEON TO THE W. W. BACKUS HOSPITAL, NORWICH, CONN.

The following is the history of an instructive case of *x*-ray injury. The patient was Dr. John Weldon, of Willimantic, Conn., a man forty years of age, weighing one hundred and eighty-six pounds, and six feet in height, a member of the non-resident staff of this hospital, and a surgeon of large practice. The main points of interest are the following:

(1) The patient during the time of exposure, although perfectly conscious, suffered no injury nor pain. (2) Eight days elapsed before the appearance of any injury, and then only a slight dermatitis. (3) The rapidity of the changes in the tissue involved a truly mummified condition in which the lesion appeared dead, yet had sufficient vitality to be indestructible. (4) To the touch the induration was hard and unyielding and not at all sensitive, but at certain points it would bleed on friction. (5) The severe paroxysms of excruciating pain upon the application of any poultice or wet dressing, showing the induration to be highly absorbent. (6) The marked constitutional symptoms and rapid wasting without much rise of temperature.

This is a brief synopsis of the case to which I was called on September 12, 1899. I found the patient prostrate upon his bed; temperature, 99° F.; pulse, 104; a mere shadow of his former self, having lost over forty pounds in weight, pale and emaciated; he had no appetite, and could not sleep night or day except under the influence of large doses of morphine. The inability to sleep was the result of a severe pain, burning in character, which he described "as if red-hot coals were applied to the part."

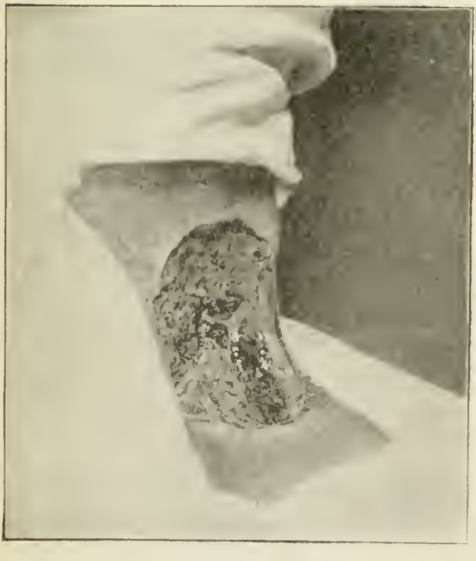

Fig. 1.

On examination I found in the left groin a large lesion, oval in form and five inches in the longer diameter. The centre of the lesion was at the point where the femoral artery emerges from beneath Poupart's ligament. The accompanying illustration (Fig. 1) represents the injury as I found it. The color was a very dark gray, except here and there were dots, slightly red; there was neither discharge nor odor; the skin on the edges appeared healthy.

The patient gave the following history: "On March 18, 1899, for the purpose of procuring a skiagraph of my left hip joint, I exposed the part for forty-five minutes at a distance of five inches from the tube, which was of medium vacuum, of a static machine the plates of which revolved two hundred and twelve times a minute. During the time of exposure there was no sensation of any injury nor of the slightest pain. My first sensation of any harm was an itching in both groins, a little more intense in the left, which occurred a week after. Inspection revealed an acute dermatitis in that region, which rapidly increased, so that at the end of the second week the erythema covered the lower third of both sides of the abdomen and upper third of both thighs. At this time the pain became so intense on both sides, but more on the left, that I was obliged to give up my practice and take to the bed. The inflammation went on to the formation of vesicles, then bullæ, and at the end of the third week the epidermis of the affected area came away. By the application of a powder of the stearate of zinc in about ten days the right side had entirely healed, and the left also, with the exception of a space in the groin as large as the hand, which presented a red, shining appearance and radiated a great amount of heat, with irregular, sharp, lancinating pain. About the middle of June, three months after the exposure, the surface of this lesion commenced to be covered by a thin yellowish membrane, at first easily removed, but only to return quickly, and which soon became so firmly adherent that I could not remove it.

"About July 1st the pain became so intense that rest or sleep could be procured only by large doses of morphine. On advice, I went into the country for a change and in search of rest, which proved so beneficial that the use of morphine was discontinued, but there was no improvement in the healing of the injury. August 1st, I returned to Willimantic with the hope of resuming my practice, having been encouraged by the relief from pain. This hope was doomed to disappointment, as in a few days the pain returned in a form more severe than ever, and again I was compelled to resort to morphine. Through the use of this drug I tried to continue my practice, but the system becoming tolerant, the pain more severe, in the last days of August, completely exhausted in body, broken in spirit from four and one-half months of suffering, I was again forced to take to the bed, and then the removal of the membrane was attempted by the use of the curette.

"During these months I consulted many experts in different cities, both by person and by mail, communicated with every physician of whom I had heard as having any experience with *x*-ray injuries, and read every scrap of literature I could reach on the subject. The consensus of opinions was, 'Use mild remedies, nature will effect a cure.' Upon this advice I have used almost every sedative ointment in the pharmacopœia and applied many lotions and poultices. Some of the ointments afforded relief, but any poultice or wet dressing of whatever nature, when applied, would in a half-hour or less produce the most agonizing pain, as if live coals of fire were placed upon the part."

Recognizing the gravity of his case, I advised his immediate removal to the W. W. Backus Hospital at Norwich, Conn., in which advice the doctor acquiesced, and he entered the institution on the following morning, September 13, 1899. At this time his pulse was 112; temperature, 99.2° F.; respiration, 26.

I hoped to avoid a radical operation by assisting the separation and causing the softening of the leathery tissue, and so ordered the application of Labarraque's solution 1:15. This at first was grateful, but pain was soon present and rapidly increased to such a degree that at the end of an hour the patient suffered such agony as I never before witnessed. The dressing was promptly removed, and a large dose of morphine gave the patient relief in the course of about three hours.

The hospital staff was called in consultation, and it was decided to remove the diseased tissue by the knife. The following morning, September 14, 1899, the patient was etherized, and in the presence of the staff I operated as follows: Beginning at a point one inch external to the femoral artery, I made an exploratory incision two inches in length down through the diseased tissue, which was as difficult to cut as sole leather, and found it, to my surprise, to be fully one and one-half inches in thickness and firmly attached to the muscles of the thigh by the coalition of the healthy with the diseased fibres. To remove the diseased tissue, I dissected the skin around the circumference of the oval lesion, and found that the induration extended nearly two inches under what appeared on the surface to be the line of demarcation; this making the external injury seven and three-fourths inches in diameter, as is shown by illustration (Fig. 2). Beginning at its external border, I dissected the lesion from its deep muscular attachments. In so doing, on the thigh I split the sartorius, pectineus, adductor longus, on the abdomen the external oblique and rectus. Poupart's ligament was exposed. The femoral artery, which was found to be embedded in the induration where it formed a complete sulcus, was carefully dissected from the diseased mass and stood out prominently from the floor of Scarpa's triangle uninjured, with small tufts of the diseased tissue adherent to its coats, which were clipped away later.

The time required for the operation was about one and one-half hours. The shock was slight, and the patient rallied very nicely. The first dressing was bichloride 1:2,000. The next day hot Labbaraque's solution 1:10 was substituted, to be changed every three hours, with irrigation daily with the same solution. This treatment was continued until September 28, 1899, when the wound was found to be in a condition to receive skin grafts, and saline dressing was used. On the morning of the 29th, by Reverdin's method two hundred and ninety skin grafts were placed in position and properly protected. On October 2, 1899, the wound was inspected, and it was found that fully eighty per cent. had taken. These had coalesced so rapidly that on the 8th of October the entire surface was bridged over, but on the 9th the new skin did not appear so healthy; to stimulate and prevent sloughing, a mixture of bovinine two parts and balsam of Peru one part was applied. This treatment had not the effect desired, and many of the dusting powders were tried, but in spite of any treatment, to my chagrin, many of the grafts sloughed.

From the day of the operation all pain ceased, and all opiates were withdrawn except small doses of deodorized tincture at night to give sleep, and this was discontinued September 26th. The only medicine administered was strychnine, gr. $\frac{1}{60}$ every four hours, and tincture of iron, 8 drops every two hours. Sleep, appetite, and strength rapidly returned, and the patient was able on the 10th of October to ride out. The wound had contracted and now was four and one-half inches in diameter; many of the skin grafts were still adherent. On October 14th he left the hospital and returned home fairly well, though walking lame.

The doctor visited me at my office on October 21st, and said he had been in active practice since his return and was fast regaining his strength. The wound had contracted to four inches, but every graft had sloughed. He was still lame. He was using a dusting-powder of aristol and zinc. I advised the continuance of the powder and again to try skin grafts.

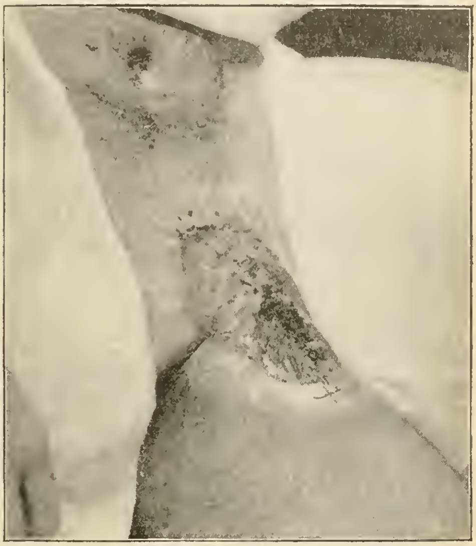

Fig. 2.

On December 6th he again visited me. The wound had contracted to two inches. He had not tried the grafts, as he considered them unnecessary. He had regained his former weight and strength. The lameness remained, but with some improvement and with the partial loss of important muscles, and the healing of the wound by cicatricial tissue. I fear some grade of permanent lameness, the only evil resulting from a serious injury which once aimed at destruction and death.

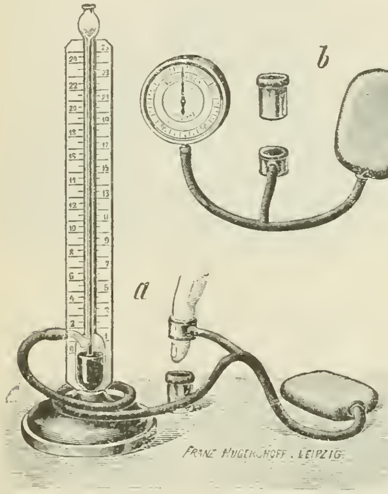
THE TONOMETER, A NEW INSTRUMENT TO DETERMINE THE AMOUNT OF BLOOD PRESSURE.

By HENRY L. K. SHAW, M.D.,

ALBANY, N. Y.

Dr. Morison,[1] in a recent address on the use of mercury in heart disease, spoke of the control of the blood current as being as necessary to the therapeutic domination of the body as the possession of a naval power is to the domination of the world. The main signal station of the arterial system is the radial pulse, which warns us of the approach and keeps us informed of any advance or retreat made by our enemy—disease. One of its most important junctions lies in the indication of the amount of blood pressure. Rightly to determine this is very difficult and requires practice and much experience. Recently ten American physicians, all of whom had spent a year or more in hospital or general practice, were given a number of cases in Nothnagel's clinic to examine with special reference to the arterial tension. The answers were so varied and contradictory that it seemed to have been mere guesswork, and yet some of these men had had large experience. The result can be taken as an index of the average physician's ability to estimate correctly the amount of blood pressure. Most physicians are content with noting the pulse frequency and rhythm, and make the common error of considering a bounding pulse to be one of high tension.

A number of appliances have been constructed to determine the amount of blood pressure, but most of them are complicated and require much skill to manipulate. Sahli[2] says that any improvement in the methods for registering the blood pressure is greatly to be welcomed owing to the extremely great clinical importance of arterial tension. The best-known later instruments are those of Mosso,[3] Hürtle,[4] v. Frey,[5] and v. Basch.[6] The sphygmomanometer of Basch is the only one that could be called a practical clinical instrument, and it has many faults. It consists of a metal manometer connected by rubber tubing with a small cup-like attachment called the pelotte. This instrument is air-tight and filled with air. The pelotte is placed directly upon the radial or temporal artery with sufficient pressure to stop the blood stream. The pressure is slowly reduced until the pulse is felt by a finger placed on the distal side of the pelotte. The instant this is felt the amount of pressure recorded by the manometer should be the amount of arterial blood pressure. The personal error here is liable to be great, as the accuracy depends upon the delicacy of the sense of touch, which we have shown is not always reliable, so that in reality very little is gained from the employment of this apparatus.



Professor Gärtner, who holds the chair of experimental pathology in the University of Vienna, demonstrated last June before the Gesellschaft der Aerzte in Vienna an instrument he had devised to estimate the amount of blood pressure. This instrument he called the tonometer.[7] It consists of a pneumatic ring, mercury manometer, rubber ball, and rubber tubing. The ring is the most essential part of the apparatus. This is made of metal, and is about an inch in diameter and half an inch in height. A hole is bored through one side, in which a small metal tube is inserted, which serves for the attachment of the rubber tubing. The inner surface is covered with a very thin rubber membrane, which is tightly wired above and below on the outer surface of the ring. A piece of rubber covers the outside, and no air can enter or escape save through the small metal tube.

The mercury manometer is very simple, consisting of a glass tube with a bulb filled with quicksilver. A scale is attached to the glass tube, which registers as high as 260 mm. The rubber tubing is T-shaped, with the ring, manometer, and rubber ball attached on the free ends. These parts are separable, and by the use of leather washers the joints are air-tight. Pressure on the ball forces air into the mercury bulb and rubber ring, raising the mercury in the one and distending the membrane in the other. With sufficient pressure the lumen of the pneumatic ring will become obliterated. To regulate slowly the pressure on the ball there is a small wooden press with a thumb-screw attachment, and the ball is placed inside this press.

Professor Gärtner has designed a metal manometer which is more convenient for transportation, and the whole apparatus can be carried in the pocket. As the metal manometer is not always accurate, its reading can easily be corrected by a comparison with the mercury tube. This is done by removing the pneumatic ring, attaching the small manometer, raising the quicksilver to the height of 100 mm. in the tube, and seeing the amount registered by the metal manometer.

To ascertain the amount of arterial tension the pneumatic ring is slipped over the second phalanx of one of the fingers or the first phalanx of the thumb. It must not cover a joint and is so placed that the finger can easily be bent. The end phalanx is then made anæmic by slipping a small rubber band over the finger tip and rolling it down the finger as far as the ring. A pressure is now made upon the rubber ball stronger than the arterial blood pressure. The rubber band is removed and the finger remains anæmic. The pressure on the ball is slowly and evenly released until the finger tip becomes hyperæmic, and the amount of pressure is read on the manometer. The hyperæmia is very easy to recognize, and owing to the compression of the veins the return flow is hindered and the finger tip becomes intensely red.

The principle of the apparatus is as simple as it is ingenious. The digital arteries are so compressed by the pneumatic ring that no blood can pass through. This is shown by the finger tip remaining anæmic. The pressure in the ring is gradually reduced, and the instant the pressure in the ring is equal to or a little less than the pressure in the arterial system the blood will flow through the arteries and the finger tip will become hyperæmic. The manometer records exactly the amount of pressure exerted upon the finger, so when the finger tip becomes red the amount registered by the manometer is approximately the amount of blood pressure in the digital arteries. These arteries are admirably adapted for the purposes of the tonometer. They are close to the surface and near the bone, and so can be completely compressed by the pneumatic ring. The epithelium over the arteries is generally thin and soft, and cases in which the epidermis is thickened enough to interfere with a correct reading are very rare. The great advantage this instrument possesses is in the substitution of the sense of sight for the sense of touch. The instant the finger tip becomes red the patient experiences a marked pulsation and can, if intelligent, control in some measure our sense of sight. I have made many correct determinations upon myself without rendering the finger anæmic, and depended solely on feeling the pulsation.

The ease and rapidity of application and determination make the tonometer a thoroughly practical instrument. The entire process need take but fifteen to thirty seconds. It is very easy to apply on children from earliest infancy. The measurement may be taken with the patient sitting up or in the recumbent position. It is necessary, however, that the hand be on the same level as the heart, for well-known hydraulic reasons. I have found that the difference in blood pressure in my hand between the sitting and standing positions registers nearly 30 mm. This shows the delicacy of the tonometer. The patient must rest quietly during the estimation, because coughing, straining, etc., raise the blood pressure. From a vast number of trials Professor Gärtner has found that the normal blood pressure as registered by the tonometer is between 100 and 130 mm. Anything above or below these figures indicates an abnormal pulse tension. The highest reading obtained as yet by Professor Gärtner is 240 mm. A number of physicians are now working on the blood pressure with the tonometer, and within a few months many articles bearing on this subject will appear in the German periodicals.

My attention was directed to the Gärtner tonometer in the first clinic held by Professor Nothnagel last October, where he demonstrated the use of the tonometer and recommended it very strongly. I subsequently learned that it was employed as a matter of routine in his clinic, in which his assistants warmly indorse its use. It is also used in the medical clinic of Professor Neusser. Before the recent congress in Munich, Professor v. Ziemssen said that the determination of the blood pressure was taken systematically in his clinic, and often was of diagnostic value. Three American physicians who spent some weeks this past summer studying the treatment of heart affections at Nauheim have told me of the regular use of the sphygmomanometer by Professor Schott and his assistants.

The object of this article is to call the attention of the profession in the United States to the Gärtner tonometer, and to point out a few of the conditions in which it could be employed with advantage. Broadbent,[8] in his classical work on the pulse, speaking of high tension, says: "Unduly high pressure in the arterial system or high tension of the pulse is a condition worthy of careful attention and study. It explains many of the forms of failing health at and after middle age through lesions of the brain and heart. It points out tendencies which later result in serious illness or fatal disease, and its recognition often directs us to measures by which ailments may be relieved, and enables us to foresee and sometimes to avert premature death."

A most important condition to recognize early is the so-called idiopathic cardiac hypertrophy. Seitz, of Zurich, was the first to describe this disease, which he found very frequently among the peasants in Switzerland, who are accustomed to climb mountains, carrying heavy loads. If care is not taken, it will finally result in relative valvular lesions and insufficiency of the heart muscle with its accompanying anasarca, ascites, and passive congestions. In the stage of compensation there is always a high-tension pulse. There is little doubt that many of our active college athletes develop this condition. Professor Gärtner[9] has made some interesting experiments upon bicycle riders. A long ride with severe exertion causes only a slight increase in the pulse tension if the rider is in good training. On the other hand, it was found that the riders who were not in training had after a short preliminary rise a prolonged and marked low arterial tension. This opens an important field for further investigations.

In arteriosclerosis we have a loss of elasticity in the vessel walls, and in order to maintain the circulation the left ventricle works harder and hypertrophies, and the blood pressure is greatly raised. The importance of recognizing the amount of pulse tension is well known, and in advanced cases it is impossible to determine it from the radial artery. The tonometer renders great service in these cases, as the digital arteries are so small that even in a high grade of general arteriosclerosis there is no difficulty in making a correct estimation.

In nephritis the increase of tension is constant and forms one of the leading symptoms. Recently in Nothnagel's clinic I saw two cases of chronic contracted kidney which will illustrate the diagnostic value of the tonometer. One was a stout individual who was passing daily from 1,800 to 2,600 c.c. of urine with low specific gravity. A trace of albumin was present, but very faint, while repeated examinations failed to reveal casts. Owing to the extremely thick chest walls the apex could scarcely be felt, the heart dulness was not accurately mapped out, and the heart tones were not distinctly heard. The pulse was small, and the tonometer registered a blood pressure of over 200 mm., and thus confirmed a diagnosis otherwise presenting some difficulties. The other case was similar in many respects, only the heart dulness and sounds were obscured by a marked emphysema. Here the blood pressure was 225 mm. The tonometer may render a diagnosis of chronic nephritis without a microscopical examination of the urine. The great importance of this disease and of its early recognition to life insurance companies suggests the employment of the tonometer as a part of the routine in all their medical examinations.

In chronic lead poisoning there is always a high-tension pulse, and the tonometer may here be of diagnostic value.

An increase in the volume of blood brings about a higher arterial tension, and in such cases a copious bleeding would be beneficial. If this condition continues the left ventricle becomes hypertrophied. Broadbent[10] claims the high tension in acute nephritis is due to an increase in the blood volume caused by retention of the urinary water. This might explain the high tension in the "Munich beer heart," especially when a certain subjective sense of pressure is not frequently relieved by the beer drinkers.

Capillary resistance is a most important cause of increased pulse tension. A lack of oxygen in the red blood cells causes a higher blood pressure. This is the case when carbon dioxide is in excess and accounts for the high tension in cyanosis and dyspnœa. In Professor Neusser's clinic the high-tension pulse in pleurisy with effusion is taken as the indication when to aspirate.

Foster[11] has proved experimentally that many drugs and poisons injected into the blood raise the pressure by increasing the capillary resistance. The products of auto-intoxication and imperfect metabolism circulating in the blood act in the same way, and the origin of some obscure symptoms may possibly be traced by the presence of a high-tension pulse.

The tonometer is useful to control the effects of certain drugs and to indicate the line of remedies required in particular cases. It thus favors a rational use of therapeutic measures. The knowledge obtained by its employment can be utilized in the prophylaxis of many disorders. The value of recognizing high or low arterial tension in the prognosis of certain diseases is too well known to be repeated here.

In conclusion I would say that the state of the pressure in the arterial system plays an important rôle in medicine, and it is not always recognized by the average physician; that in the Gärtner tonometer we have a simple, practical, and accurate clinical instrument to determine the amount of arterial tension; that its value lies not only in scientific investigations, but also in the daily practice of the general practitioner.

MUCINÆMIA, AND ITS RÔLE IN EXPERIMENTAL THYROPRIVIA.

By I. LEVIN, M.D.,

NEW YORK.

It is a well-established fact that an organism deprived of its thyroid, either through disease (myxœdema, cretinism) or through an operative removal of the gland, is suffering from some kind of an auto-intoxication. Some substance, which has either been previously transformed by the cells of the thyroid, or else neutralized by some other substance produced by the gland, accumulates in its absence in the blood and poisons the organism. But what is the nature of the substance or substances? This question has hardly been approached yet experimentally in a direct way. The discovery of an increased amount of mucin in the tissues in myxœdema as well as in thyroidectomied animals led Horsley and others to suppose, *a priori*, that the symptoms of cachexia thyropriva may be due to accumulation in the blood of mucin, which is normally transformed by the thyroid. It seemed to me all the more desirable to test the matter experimentally, as I was unable to find in the literature any physiological or pharmacological study of the influence of mucin on an organism. I shall limit myself here to an epitome of my work. A more detailed account of it, together with the tracings and other experiments bearing on the subject, is now in course of preparation and will appear elsewhere.

In order to study the relation between mucinæmia and the thyroid I availed myself of the fact that rabbits stand thyroidectomy a great deal better than carnivorous animals. Until lately it was universally accepted that thyroidectomy was not fatal to rabbits. Gley in his work endeavors to show that the operation is fatal to rabbits if all the parathyroids are also extirpated. But even with him only a small percentage get an acute cachexia, and these die not later than within three days after operation. The rest either recover entirely or emaciate and die a few months after the operation. I have obtained identical results in my simple thyroidectomies on rabbits. A few of the animals die within twenty-four to forty-eight hours, but by far the greater part survive. Taking this as a basis I did the following experiments: A solution of mucin in one-per-cent. sodium carbonate was injected hypodermically into eight normal and nine thyroidectomied rabbits. The former remained healthy, while of the latter only one survived. Some of the thyroidectomied rabbits died within forty-eight hours after the injection, while they had previously survived the thyroidectomy from eleven to twenty-five days. Further to study the influence of mucin on the nervous system of a normal animal, I examined the influence of an intravenous injection of a mucin solution on the blood pressure of the dog. The experiments showed uniformly a fall of the blood pressure, even after both vagi and the splanchnic nerve were cut. Subsequent stimulation of the splanchnic again increased the blood pressure. The fall was consequently due to the direct depressing action of mucin on the vasomotor centre in the medulla.

The conclusion to be drawn from this work is, that mucin accumulated in or introduced into the blood of a normal organism produces a certain depressive effect upon the central nervous system; that it is not fatal to a normal organism, and is decidedly fatal to one deprived of its thyroid. Mucinæmia then, one may conclude, is the pathological condition of an organism resulting from the absence of the thyroid function; but this conclusion does not exclude the possibility of other abnormalities arising from the same cause.

GONORRHŒA IN ITS RELATIONS TO THE MALE ADNEXA.[1]

By E. WOOD RUGGLES, A.M., M.D.,

ROCHESTER, N. Y.

A quarter of a century ago it probably seemed as if the last authoritative word on the subject of gonorrhœa had been said. But just as the discovery of the tubercle bacillus, by Koch, gave a new and almost violent impulse to the study of tuberculosis, simplifying its diagnosis, explaining its symptoms, and giving hopes —alas, not yet realized!—of a successful specific treatment, so the discovery of the gonococcus by Neisser, of Breslau, in 1879, has wonderfully broadened and deepened our knowledge of the character of gonorrhœal processes and led to really remarkable results in their treatment.

For example, many cases, such as were formerly diagnosed as gonorrhœa and supposed to be rapidly cured by some new method of treatment, are now known to be simple urethritis, caused by leucorrhœal contagion, or even by decomposing secretion under a tight foreskin.

On the other hand, the previously unsuspected virulence of the gonorrhœal infection has been clearly established, by the discovery of the gonococcus in suppurating buboes, in inflamed joints, in suppurative epididymitis, in palmar abscess, and recently in the endocardium, in two cases of death from gonorrhœal endocarditis following gonorrhœal rheumatism.

But my subject limits me to the consideration of the effects of gonorrhœa upon the "male adnexa," if I may be permitted thus to christen the testicle, epididymis, vas deferens, ejaculatory duct, seminal vesicle, and prostate gland. Acute inflammation of these organs may occur at any period of the disease, though, as a rule, rather late than early. This is to be explained, not merely by the somewhat later development of posterior urethritis, but more particularly by the minuteness of the ejaculatory and prostatic ducts and their oblique opening into the prostatic urethra, which without doubt causes their occlusion during the hyperæmic stage. As the swollen membrane loses its turgidity, the mouths of the ducts become more patulous and the entrance of germs less difficult. In cases which occur early, imprudence on the part of the patient, such as coitus, bicycle or horseback riding, drinking, etc., are at fault, or else meddlesome treatment—for example, the injection of astringent, non-gonococcicidal remedies, passage of sounds, rectal massage.

Inflammation of the testicle itself caused by gonorrhœa is comparatively rare, or, if it does exist, is of minor importance, compared with the extreme severity of gonorrhœal epididymitis. The symptoms of the latter are what might be expected from the peculiar conditions—the swollen tissues being constricted from without and thus caused to press with double force on the hypersensitive testicle. The literature of epididymitis is easily accessible to all, so I will only pause to consider its most far-reaching consequence, in the tendency to obliteration of the vas deferens at some portion of its lumen. Occurring on one side only, this would matter less, as the diminution in number of the spermatozoa in the semen, oligozoöspermia, rarely causes sterility. But when epididymitis has affected both sides, azoöspermia and absolute sterility are the rule. Finger collected the histories of two hundred and forty-two cases of bilateral epididymitis, in two hundred and seven of which, eighty-five per cent., the semen contained no spermatozoa.

---

[1] Read before the Rochester Pathological Society, December 15, 1899.

He also found, in his investigations concerning sterility, that in several cadavers one or both ejaculatory ducts had been obliterated at or near their opening by a posterior gonorrhœal urethritis. When bilateral this condition would, of course, cause sterility. The sharp pain at the instant of ejaculation, which we not infrequently meet, is without doubt in many cases referable to the impingement of the semen upon the mouth of the duct, pathologically narrowed in the same manner. This pain, in some cases, produces a reflex disturbance of the ejaculatory act and its sudden inhibition, so that little or no semen leaves the urethra, and thus may also give rise to sterility.

Funiculitis, or inflammation of the spermatic cord, may cause obliteration of the vas deferens quite independently of epididymitis, and, if bilateral or in connection with epididymitis of the opposite side, also produces sterility.

Acute prostatitis is a much rarer complication of gonorrhœa than epididymitis, though without doubt it is often unrecognized, the symptoms of its milder forms being the same as those of posterior urethritis—frequent micturition, tenesmus, pain at the neck of the bladder, radiating into the scrotum or thighs, dull pain or uneasy feelings in the rectum, etc. With rest in bed, elevation of pelvis, hot rectal douches, and calming suppositories these cases can generally be confined to the follicles of the gland and do not go on to suppuration. If this does occur and breaking down in some direction seems inevitable, it is better to cut down upon the abscess through the perineum, rather than run the risk, however slight, of a rectal or urethral sinus.

Chronic prostatitis is a far more frequent disease than is generally believed. It is my conviction that sixty per cent. of the cases of chronic gonorrhœa which have run for a year or longer (excluding those with pronounced stricture), especially those cases which, seemingly cured, recur after coitus, use of beer, etc., depend upon the prostate for their continuance by obtaining from it a fresh supply of pus and inflammatory bacteria each time that the urethra has been rid of their presence. In my investigations these bacteria have rarely proved to be gonococci; they are far more often the ordinarily non-pathogenic colon bacillus or the diplococcus urethræ, which we may be sure that the most virgin urethra here present is supporting at this moment.

This is a question to which too little study has been given—that of the virulence which some non-pathogenic bacteria develop under certain conditions. The bacteriologist devotes practically his whole attention to the pathogenic bacteria and to newly discovered forms of germ life, and does not interest himself in such problems as the changed life of the colon bacillus; first, when inhabiting the large intestine as a peaceful and probably helpful guest, and again in an acute attack of cholera morbus, or as an inflammatory, pus-producing germ in the urethra, the bladder, the kidney, or the prostate.

The diplococcus urethræ presents the same anomalies. Ordinarily perfectly innocuous to the urethra, it often is the agent which keeps up a post-gonorrhœal discharge for years, and it is a question whether it can ever be completely dislodged from the prostate which it has once invaded.

The pathology of prostatitis has been verified by only a few autopsies. Not being a fatal disease, material could be obtained only by dissecting every prostate in a large number of cadavers. Finger pursued this course for several months at the Rudolf Hospital at Vienna, and from all the autopsies collected only a dozen cases. He found two kinds of lesions. In the one the follicles were cystic and filled with an enormous amount of desquamated proliferating epithelium. In the second group the lesions were similar, with the addition of numerous pus cells. This corresponds to what we should expect from the changed secretion, only I am positive that in the latter group nearly every case would have furnished a fine culture of colon bacilli or diplococci urethræ, or both, had they been bacteriologically examined. In regard to the first group, I must say that, in my experience, in all the cases in which symptoms seemed to be produced by the prostate, its secretion contained numerous pus cells. In my opinion group first consists of cases of true prostatorrhœa and not prostatitis.

The physical diagnosis of prostatitis is not easy without long practice by the finger, and even then it seems as if each observer has a different idea of what the feeling of a normal and of a diseased prostate is. To my finger the normal prostate feels like a smooth, rather resistant, firm, rounded body, ordinarily as large as an average horse-chestnut, with a longitudinal furrow separating its lower surface into two lobes. The alterations which I find associated with disease are principally in the line of loss of firmness, a doughy, boggy feeling, not as a rule general, but forming compressible areas—"Dellen," the Germans call them—between hummocks of normal or hardened tissue, unilateral as a rule, though frequently found in both lobes. Out of these "Dellen" the discharge can often be literally milked. Frequently, however, no change in its contour or firmness is ascertainable, and yet the expressed secretion contains abundant pus and bacteria.

The microscopical finding is then the true arbiter as to the condition of the prostate, and without it no satisfactory results can be accomplished. This is no less true of the diagnosis and treatment of acute and chronic gonorrhœa in general. The indications change with the alterations in, or absence of, bacteria, and there is not the slightest doubt that it would be exactly as just to the patient to treat any febrile disease without the clinical thermometer as to treat gonorrhœa without the frequent, almost daily, use of the microscope. In fact, given the enormous prevalence of the disease and the widespread evils which result from chronic gonorrhœa, including the martyrdom and unsexing of innocent wives, the consequences are perhaps worse. And, after all, the pulse and feel of the patient are far more accurate indications of the presence or absence of fever than are the looks and consistency of a urethral discharge guides as to its bacteriological condition.

The prostatic secretion, if diseased, has lost its fat granules and generally the amyloid bodies, and shows a considerable amount of pus, an increased number of epithelial cells, often of the pear-shaped type, and as a rule motile bacteria.

This fact I have not seen mentioned elsewhere and attribute it to the omission of closely approximating the cover-glass and slide before completing the examination. If this be done, little specks will be seen, about pin-point size, or moving lines which either visibly oscillate, make short excursions, or else show they are in motion only by appearing at one instant as dark specks and then a few seconds later as brilliant, light-refracting points, this being caused by their leaving and approaching the point of exact focal distance. This phenomenon can be seen only by following intently one particular speck. On staining, which is difficult because of the prostatic secretion not adhering well to glass, they generally prove to be diplococci urethræ or colon bacilli, or both.

Following are the abridged histories of several cases in which the prostate gland was the real *corpus delicti*, though not previously recognized.

B. M——, salesman, twenty-six years old; heredity and general health good. His first gonorrhœa, in 1891, lasted four or five months. The second, in 1893, lasted six or eight weeks. The third, in 1896, lasted acutely only three or four weeks, but since that time he has had recurrence of the discharge after each coitus and after violent erections. He has been the whole time under treatment. In November, 1897, a St. Paul physician performed meatotomy so effectually as to produce hypospadias, an error generally committed, even by specialists. No improvement, but increased discharge, followed the operation.

Status præsens, October 12, 1898: The rather scanty, muco-purulent discharge contains pus, epithelium, and a few pus cells enclosing gonococci. Urine, first glass cloudy, second clear. Under treatment with protargol he made good progress for two weeks. Then he suspended treatment for two days and had a nocturnal emission. He returned with a thick, ropy discharge full of pus cells.

After two weeks more of similar history, on November 14th, I examined the prostate and found the right lobe boggy and expressed considerable secretion containing numerous pus and epithelial cells. With massage and irrigations of permanganate the character of the prostatic secretion rapidly improved, till on November 20th there were no pus cells. The night of the 21st he had an emission, and next day the prostatic secretion again showed pus. On the evening of the 30th he drank eight or ten glasses of beer. Next morning there was no discharge, only a slight moisture of the urethra. Removed with platinum loop, it showed some pus, epithelium, and fibrin, no bacteria. The first glass of urine was clear, with few filaments; the second clear, no filaments. He left the city for a business trip of several weeks. While away he sent a slide with specimen of discharge after first intercourse. On staining, it contained principally epithelium and almost no pus. Subsequently he practised coitus repeatedly with no return of discharge at all.

L. I——; health and heredity good. He had gonorrhœa in 1887, 1890, 1893, and the last time in 1894. Since then he has always had a discharge, which diminishes on treatment but never disappears. His wedding-day was set for Thanksgiving, one month hence. With difficulty I persuaded him to postpone it till New Year's, hoping in the mean time to gain his consent to a still longer delay.

Status præsens, October 23, 1898: He has a muco-purulent discharge; it contains pus, epithelium, and fibrin, and is swarming with secondary bacteria; no gonococci. First glass of urine was cloudy, the second clear. Under treatment with bichloride of mercury the bacteria disappeared, and the discharge was aseptic for six days, when unmistakable gonococci appeared, these having been undoubtedly kept isolated in the fundus of the Littré glands or in the prostate by the superior power of resistance of the secondary bacteria. The gonococci not disappearing so speedily as desired, I massaged the prostate and obtained a secretion containing many pus cells and some gonococci. Massage and irrigations got rid of the gonococci in sixteen days. For some time afterward the very slight watery discharge contained extra-cellular diplococci, proven non-gonorrhœal by Gram's stain. With prostatic massage, irrigations of permanganate, and posterior instillations of protargol, this case progressed gradually to perfect recovery.

As a medical curiosity I might mention that, though my patient's fiancée knew of his having gonorrhœa, they both absolutely refused to postpone the wedding later than New Year's, but consented not to practise intercourse till I should permit it. Four weeks after their marriage his condition had so improved that I was able to allow the practice of *coitus condomatus*. He has now for some time abandoned the use of condoms, without infection of his wife, and remains perfectly well himself.

M. W—— was also a candidate for matrimony. He had acquired gonorrhœa for the third time in November, 1898. Status præsens, February 8, 1899: He feels smarting in the urethra, sometimes itching. The lips of the meatus are glued together. The discharge, muco-purulent, contains pus, epithelium, and a few intracellular gonococci. First glass of urine is cloudy and contains filaments; second cloudy. The prostate is boggy and I expressed considerable secretion containing pus and epithelial cells.

Treatment: Massage of prostate, permanganate irrigations, anterior injections and posterior instillations of protargol, gradual dilatation to 34° French during two and one-half months. The patient was married in May. He is perfectly well now, as is also his wife.

A further indirect effect of chronic prostatitis is the production of dead spermatozoa, necrospermia, and consequently sterility. Fürbringer discovered the fact, subsequently confirmed by Burckhardt and Finger, that the spermatozoa in the seminal vesicles are motionless, and that the admixture of the acid prostatic secretion is necessary to impart motility and thus render them capable of fructifying the ovum. In these cases of prostatitis, attended with the formation of pus, the reaction becomes neutral, and with considerable pus alkaline. These patients have necrospermia and are sterile.

Seminal Vesiculitis.—Owing to the length of this paper I must refer my readers for a full description of the etiology, pathology, symptoms, and treatment of this disease to Dr. Eugene Fuller's most excellent work on "Disorders of the Male Sexual Organs," in which he handles the subject in a masterly manner. According to him, gonorrhœa is the cause of almost all the cases. He certainly errs, however, in practically denying the existence of chronic prostatitis and attributing these cases to perivesicular inflammation. In several of my cases the contents of the vesicles, as obtained by massage, were absolutely normal, with no pus cells whatever, and yet the prostatic secretion was frankly purulent.

The histories of two cases, one acute, the other chronic, will serve to give a fair clinical picture of many phases of the disease:

G. H——, twenty years old; heredity and previous health good. His last coitus was on April 3d. He noticed smarting April 7th, and discharge April 9th. Status præsens, April 1, 1899: Small penis, very long foreskin; profuse, thick, yellowish discharge, containing pus, epithelium, and a moderate number of gonococci. Urine, first and second glasses cloudy, third clear. He has great pain on urination, and painful erections. Treatment: irrigation with permanganate 1 : 6,000, protargol injections 1 : 200. Part of the irrigation fluid entered the bladder, though I was trying to confine the irrigation to the anterior urethra. I believe that this atonicity of the external sphincter accounted for the development of posterior urethritis so early in the disease. Under this treatment all the symptoms improved for a few days. During this time he noticed blood on urination, and I found just within the meatus and occupying the lower half of the anterior one-eighth inch of the urethra an ulcerated surface, covered with a thin, whitish membrane. He already had enlarged inguinal glands in both groins, too indolent in character for chancroid, and I believed I had to do with a urethral hard chancre, acquired through a previous coitus. Following the Vienna school, I used no treatment, but awaited the development of secondary lesions. The ulcer healed quickly; no roseola nor other secondary manifestations have occurred. (Recently I have seen another case of acute gonorrhœa with a similar lesion in the urethra, and am awaiting the development of secondary symptoms or the contrary to see if a new symptom of acute gonorrhœa should be described.)

At the end of the first five days of treatment he felt so much better that, contrary to my directions, he took a long bicycle ride. The next day there was an increased discharge, with more gonococci, and both glasses of urine were frankly cloudy. Two days later he had chills and fever, 99.8° F. Also complained of a muscular spasm in the penis, with sudden stoppage of urination. The next day, April 24th, he felt considerable pain after the irrigation, so I instilled ♏ xxx. of a two-per-cent. cocaine solution into the posterior urethra. This seemed to accentuate his distress, and he ejected it immediately, following which came a gush of pus. Microscopical examination showed this to contain a mass of pus cells, some epithelium, and many spermatozoa. The diagnosis was made at once: acute seminal vesiculitis, gonorrhœal in character, for a fair number of these pus cells contained gonococci. The temperature was 99.8° F.; pulse, 94. On gentle rectal palpation the right seminal vesicle proved to be dilated to the size of a small hen's egg, smooth and hot. I put him to bed, elevated the hips, drew the scrotum well over on to the pubes, and gave him urotropin gr. vi. t.i.d., and suppositories of opium, belladonna, and hyoscyamus every four, then every six hours.

April 25th: He feels better. There is no discharge, but the meatus is moist (the discharge generally stops entirely till the acute attack is over). There are less tenesmus and sudden stoppage of urination. Temperature, 101.4° F.; pulse, 98. He was given quinine, gr. viii. at 9 A.M.; gr. vii. at noon daily.

April 26th: Temperature, 9 A.M., 98° F.; 5 P.M., 98.6° F. He feels better and has less pain on urination. The right seminal vesicle is a trifle smaller and is not hot.

April 27th: Temperature, 98.4° F. There is a quite profuse discharge, containing pus, epithelium, fibrin, and numerous diplococci, none intracellular. Both glasses of urine were cloudy.

April 29th: Temperature, 98.2° F. He has no pain except in the glans. The urine is much clearer; it contains pus, epithelium, colon bacilli, and gonococci (many of them extra-cellular, but verified by Gram's staining). The patient is up and around the house part of the day.

April 30th: His condition is the same, save that the seminal vesicle is smaller; it is not larger than the end of the second finger.

May 2d: He has improved considerably. There is some pain in the glans on urinating, with much tickling in the urethra. The seminal vesicle is about the same size. I used some pressure in examination, and at the end of urination there was a considerable gush of grayish, inspissated matter, consisting of pus, some crystals of calcium oxalate, and spermatozoa.

From this time on he gradually improved, a hot rectal douche (with Kemp's tube) assisting greatly in restoring tone to the vesicle, and a little later I employed massage, beginning very gently. The patient was discharged June 24th. He returned for examination August 7th, after a week of beer drinking and furious bicycle riding. There was no discharge; the first and second glasses of urine were clear as crystal and contained no filaments.

Chronic seminal vesiculitis. I shall make only one remark in preface to this interesting case, that the difficulty of recognizing the normal or only slightly altered seminal vesicle at all with the examining finger is as much more pronounced over that of finding the prostate as is the normal ovary more difficult to palpate than the uterus. With large development of adipose tissue it becomes almost impossible.

W. W——, twenty-nine years old. Heredity neurotic; the patient was formerly fairly healthy, though a hypochondriac. He first had gonorrhœa in 1894. The discharge lasted several months; he was then treated by dilatation with sounds, which was followed by epididymitis. He has never been well since, and has morning drop daily.

Status præsens, March 19, 1899: He micturates five or six times between meals, rarely after being abed. When the desire comes, he feels a stinging sensation, and if situated so that he cannot urinate, the pain increases, even to making him faint. He showed several symptoms of general neurasthenia which I will not enumerate. The morning drop contains pus, fibrin, and epithelium, but no bacteria. The urine is slightly alkaline; first glass cloudy with filaments, second slightly cloudy. The centrifuge showed pus, epithelial cells, particularly pear-shaped and active bacteria. The next day he appeared to be suffering from an attack of cystitis. Micturition occurred every half-hour in the forenoon, and every fifteen or twenty minutes in the afternoon, till he was fairly exhausted. As he said, "the urine fairly shoots out," sometimes before he was ready. He has stinging, burning pain in the glans after urination.

Suspecting the seminal vesicles or prostate to be at fault, I examined them gently per rectum and found the right seminal vesicle as large as a small hen's egg and extremely painful. I expressed part of the contents, and had the patient urinate in a conical glass. There appeared a sediment seven-eighths of an inch deep, composed of the characteristic moonstone-like bodies, varying from the size of a pinhead to that of a small pea. Examined microscopically, these consisted principally of pus, motionless spermatozoa, and a few epithelial cells. The massage was followed by instillation of a one-half-per-cent. solution of nitrate of silver into the posterior urethra.

March 22d: He feels considerably better, and urinates less often. The instillation of silver was repeated.

March 24th: He is very much improved, and urinates only once or twice between meals. Last evening he did not urinate from 6:30 till 11 o'clock, and then had no tenesmus. Massage was done, with about the same quantity of moonstones. This was repeated every four, then every six days till April 18th, at which date the amount of moonstones was very much smaller and the bladder irritation had ceased. The patient then went on a business trip for two months. During the first weeks he felt well. After six weeks the irritation returned, and he had a constant desire to urinate by day, but none when abed.

June 21st, at his return: There was a small urethral discharge containing pus, epithelium, and fibrin; no bacteria. Massage resulted in giving one inch of moonstones in the urine. There were much pus and some spermatozoa in them. He received an irrigation of permanganate, 1:6,000.

June 22d: He feels about the same. There is a gush of pus after irrigation, probably from the seminal vesicles, though no spermatozoa were visible. Urine, first and second glasses cloudy, with much pus and many active bacteria. Urotropin, gr. vi. t.i.d., was given.

June 23d: Improvement; he urinates only two or three times between meals.

June 25th: Massage showed a much smaller quantity of moonstones and pus relatively less.

On returning from my vacation (June 28th to July 17th) the patient informed me that he had felt well during the whole time. But very little material could be expressed from the seminal vesicles, and its character was greatly improved. On July 18th, 19th, and 20th he received irrigations, and on July 23d massage and irrigation.

He then went again on a business trip, and wrote me nearly two months later, to say that he had no tenesmus or irritation whatever.

As might be expected, inflammation of the seminal vesicles produces important, yes, vital, changes in the fructifying power of the semen. These organs are not merely storehouses for the semen; they are also glands and supply an intrinsic part thereof, which serves to dilute the testicular product and preserve the viability of the spermatozoa. This is proved by the fact that in both the acute and the chronic form of seminal vesiculitis the spermatozoa in the ejaculated semen are found to be dead, or at least motionless and thus incapable of performing their function.

THE CHEMICAL RELATIONSHIP OF COLLOID, MUCOID, AND AMYLOID SUBSTANCES (A PRELIMINARY COMMUNICATION).[1]

By P. A. LEVENE, M.D.,

NEW YORK.

The morphological study of diseased organs reveals frequently the presence in the cells and tissues of the latter of substances which do not occur in the same places of the normal tissues. The nature of the substances can be detected by microscopical investigation only very rarely. The microscopical technique is inadequate to disclose the chemical nature of most of the "pathological substances," and they are then identified by their physical properties. And yet only a thorough knowledge of their chemical constitution can elucidate the process of their formation and their relationship to the normal cell constituents.

The substance predominating over any other one in the protoplasm, and most peculiar to it, is one of a proteid nature. It is, therefore, natural to expect the most changes in the proteids of the tissues, when the latter are affected by some disease. Such is, in fact, the case. Pathologists have described several forms of pathological transformations of proteids in tissues under the name of coagulational necrosis, amyloid, colloid, mucoid, hyaline substances, etc. Originally but one distinction between the latter substances and the physiological proteids was detected; while the normal proteids were found to be in the tissues in a state of solution, the "pathological" ones were coagulated. In all other respects they were similar to any proteid material. Amyloid, colloid, mucoid, and hyaline substances were for certain physical properties classified under a special group of "colloidal" substances. The studies on mucin and allied substances, however, soon disclosed that the latter were not simple proteids; that the proteid was combined in them with a reducing substance, a "carbihydrate" or "animal gum." Thus mucoid and colloid had to be regarded as substances distinct from the other colloidal substances, amyloid and hyaline.

Later it was discovered that amyloid was also not a simple proteid. As mucin and mucoid, so amyloid contained a substance capable after certain treatment of reducing Fehling's solution. There was, however, a pronounced difference between mucoids and amyloid: while in the former the "animal gum" was supposed to be combined directly with the proteids, it was in the latter combined indirectly by the aid of sulphuric acid—in a word, in amyloid the substance capable of reducing Fehling's solution was described as chondrotin-sulphuric acid.

On the ground of the latter discovery three different forms of colloidal substances had to be established: 1, Mucoid and colloid; 2, amyloid; 3, hyaline. However, certain chemical and tinctorial properties of mucin justified to my mind the supposition that the latter must have contained in its molecule an acid radical. To find the acid radical of mucin was the object of this investigation. The work was begun on tendomucin, and it was soon found that, similarly to amyloid, the mucin was a compound of proteid and of an ethereal sulphuric acid. Further, it was found that, similarly to chondrotin-sulphuric acid, the ethereal sulphuric acid of the mucin was nitrogenous, and that it yielded, similarly to the former, chondrosin. With the same object in view submaxillary mucin and colloid of a colloidal carcinoma were analyzed. These two substances were also found to be compounds of a nitrogenous ethereal sulphuric acid.

Thus it seems that the acid radicals of amyloid, colloid, and mucoid substances are very similar to each other. The investigation into the question whether the substances are only similar or identical is now in progress.

State Revenue from "Patent Medicines" in Great Britain.—According to *Tit-Bits* the popularity of proprietary or patent medicines seems to suffer no diminution. These pay a stamp duty which varies according to the price at which they are sold. In the last financial year a study of the inland revenue accounts brings out the facts that a duty of 3 cents was paid on 27,856,686, bottles or packages of medicine, a duty of 6 cents on 5,076,805; of 12 cents on 856,057; of 25 cents on 108,280; of half a dollar on 11,309; of 75 cents on 5,703. Thus the government stamp on 33,914,840 parcels of these popular medicines yielded to the national exchequer the handsome sum of $1,832,860.

Pain in the Region of the Aorta.—This is frequently referred to as characteristic of aneurism, but I have not found it a valuable or constant indication. The pain of pressure and tension, so often mentioned in the books, is not only often absent, but is almost exactly simulated in many cases of neurasthenia—in fact, in the latter condition it is of frequent occurrence. One of the most prominent physicians of my acquaintance has borne the burden of fear of aneurism for three years on account of the so-called characteristic pain, while a most careful physical examination has failed to find one confirmatory sign. Far more indicative and just as frequent, in aneurism of the arch, is a pain in the region of the fifth or sixth dorsal vertebra. I well remember a case in which this was the only symptom, so far as I could learn, though I had no personal knowledge of the history; the patient, a man forty years of age, died from rupture a few minutes before my arrival. He had been treated by a noted neurologist for spinal irritation, and the autopsy showed vertebral caries from pressure. The pain may also be found in the neurasthenic, but in these cases it is lower, opposite the solar plexus, or, as a point of second selection, about the fifth cervical.—Dr. William Porter, in the *New York Medical Journal*, December 9th.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

Publishers

WM. WOOD & CO., 51 Fifth Avenue

New York, February 3, 1900.

OUR AMBULANCE SYSTEM.

Our ambulance system and our ambulance surgeons continue to excite from time to time unfavorable criticism in the news columns of the public press, the only channel by which such criticisms can reach the general public. The wide dissemination of these criticisms or attacks makes them worth considering, especially because they are always *ex parte* and made by a more or less excited and inexperienced observer, and because the unfortunate victim of the attack, the ambulance surgeon, has no chance of making an immediate reply of equal prominence to the attack in the paper publishing it. This would introduce an element of fairness which the critics do not want.

There are many things about the ambulance system which the public does not understand, and in many particulars there are things which ought to be done better, but which under the present arrangement cannot be materially changed. The only source of any radical alteration in the methods of management of this department of hospital work is the non-medical board of managers, and if its members could be induced to accept advice from those who know about this particular department, and to spend a little money sometimes where it might not show, much could be done.

The arrangement as now in force in most hospitals in this city is that the whole of the ambulance work shall fall upon the surgical house staff. This is wrong and ought to be changed. A careful analysis of the ambulance statistics for a year in a large hospital in this city has shown that more than one-third of all calls were for individuals suffering from alcoholism with or without some slight injury, and a large number of other cases were of alcoholism combined with some disease or injury in which the alcoholism was of subsidiary importance. Furthermore, there was a very large proportion among the other calls in which the patients were purely medical, in which the element of emergency was rare or non-existent. In hot weather there were many cases of insolation, and in winter exposure and pulmonary diseases were reponsible for many calls. In order to do efficient work a man must not be overworked, and if ambulance duty were evenly divided between the medical and the surgical house staffs, as it ought to be, much would be gained. This is a perfectly fair arrangement, since the figures prove beyond question that any given ambulance call is as likely to be for a medical as a surgical condition. The arrangement would not appeal to medical juniors for obvious reasons, and probably not to boards of managers, whose *vis inertiæ* against change of any kind is always considerable; but it would undoubtedly simplify matters, and by lightening the ambulance surgeon's work make carelessness and inefficiency less likely. Coupled with this change there ought to be a rule, rigidly enforced, that every person for whom the ambulance is summoned should be taken to a hospital, where definite disposition of his case might be made by suitable authority. This rule would protect every one concerned in the matter, and would be really of special advantage to the ambulance surgeon. If he observes it, he need take hardly more responsibility than that of a trained nurse, and he will never have any unpleasant newspaper prominence, unless he is foolish enough to do something objectionable, or apparently objectionable, at the scene of the call.

When possible in large hospitals it might be well to appoint a special ambulance surgeon, perhaps with a small salary, who might be relieved at certain times by a member of the regular staff, and whose whole work should be on the ambulance and in the accident room. The emergencies which are encountered by ambulance surgeons are not such as require profound knowledge and experience, because, as we have noted, the patient has only to be taken at once to a hospital in order to place the responsibility on some officer in the hospital, presuming that the man on the ambulance has acted with ordinary care. We know that ambulance surgeons do not always behave with perfect politeness, circumspection, and good temper, but they are not the only ones who may be found fault with in this regard; and the proper way to correct such things is not to condemn the whole arrangement and all ambulance surgeons. The public is under the impression that the ambulance surgeon is getting valuable professional experience from ambulance work, and a large number of people seem to think that all hospitals receive a generous appropriation of public money for the maintenance of this part of their establishments. The work is the dreariest kind of drudgery, and the only experience in it is in learning self-control and restraint in the matter of temper. Only public hospitals receive enough public money to support their ambulance establishments. Considering the enormous number of calls, we think it remarkable that there are really so few blunders with any evil consequences—evidence, it seems to us, that a high order of skill and knowledge is not required on an ambulance; for the ordinary ambulance surgeon cannot possibly have had experience in making a rapid and intelligent diagnosis of all sorts of conditions, such as he meets continually.

Another source of friction exists in the method of sending calls for an ambulance. Most of the calls come through the police, and, reform and instruct them how we will, there will always be an irreducible residue of gross stupidity to contend with. The charge against hospitals that dying patients are driven long distances to Bellevue Hospital in order to keep down mortality figures is not well founded, as will be evident if we stop to consider that patients dying within twenty-four hours of admission do not influence the general death rate, but are put in a separate classification, "moribund on admission."

The reforms which we should suggest, and should like to see introduced, are: (1) Division of ambulance work equally between surgical and medical internes; (2) appointment, whenever possible, of a special ambulance surgeon; (3) rigid enforcement of the rule that every person for whom an ambulance is summoned should be taken to a hospital; (4) some reform, if possible, in the present method of sending calls, especially "police station calls." The ambulance surgeon himself changes too often to make it worth while suggesting reform for him. However, if he has the instincts of a gentleman, they will be evident on the rear seat of an ambulance as much as anywhere else.

THE MENACE OF THE BARBER SHOP.

In some respects New York is the slowest of American larger cities. Improvements, advances, and reforms are to be noted in many smaller communities long before the necessities of the case have sufficiently impressed themselves upon the minds of our city fathers. Though the Empire City may be late in making beneficial changes, it has usually so far benefited by the experience, and often the mistakes, of other places that, when improvements are inaugurated, they are up to date. New York has been backward in "barber-shop hygiene," which the Medical Record has advocated for a number of years. Paris has continued in the praiseworthy reforms started several years ago, and now only metal combs are allowed, and, so far as it is possible, all instruments have to be made of metal, or some substance which can be readily sterilized along with the towels, while the operator himself is expected to keep his hands reasonably clean. Pennsylvania is to be congratulated upon starting a movement in the proper direction, to secure an improvement in the conditions surrounding the barber and his work. The State board of health has circulated a series of recommendations, which, if followed, would vastly decrease the chances of spread of contagious disease in this way. Doing away with sponges and powder puffs, not using on one customer after another the same piece of alum to stop bleeding, and taking care in the use of cosmetics not to let them serve as media of transmitting disease from one person to another, are all wise suggestions.

Last month Missouri made a stand for scientific and sterile barbering. A board of examiners will see to it that the barber is qualified, among other things, to give a clean shave.

Canada is following in the footsteps of France, Austria, and Germany. The province of Quebec requires the barber, first of all, to be himself a healthy subject, free from transmissible affections. Then he must pass an examination in disinfection, and promise to apply his knowledge for the benefit of his patrons.

In connection with this important subject it is interesting to learn that Huebener, of Breslau, found pyogenic microbes in the beards of physicians eleven times in twenty-six examinations.

Flügge found that in a bearded subject there was a marked increase in the number of colonies when the beard was left uncovered near agar culture plates.

It is not, however, necessary for us to go into the minutiæ of scientific refinement in order to convince the thinking of the necessity for some regulation of the barber's business. In the October number of the *Journal of Cutaneous and Genito-Urinary Diseases* is a report on favus in which we read: "The two children now presented by Dr. Allen were American born, and they exhibited much the same appearances as the girl shown at the previous meeting. Another point was that these boys had never had medical treatment, but had been treated regularly by a barber, the applications being made in his shop. The speaker said that one of the worst cases of favus that he had ever seen in this country had been treated in a barber shop." Would it not be well for us at least to attempt to regulate the practice of medicine and surgery by the barbers of this city, compelling them to confine themselves to non-contagious diseases? For the present it would seem superfluous to tell them that Sabrazès gives in the October number of the *Journal des Maladies Cutanées* a practical method of perfect sterilization for brushes, combs, razors, etc., without injuring them. Three grams of paraform tablets per cubic metre of space are evaporated in a closed space at a temperature of 40° C., the instruments being exposed for four hours, which has been found to rid them entirely of all microbes.

MEDICAL ADVERTISING IN RELIGIOUS JOURNALS.

The decision recently arrived at by the proprietor of *The Christian Herald*, not to permit in future the insertion of any advertisement of a medical character within its pages, is one which will meet with the approbation of all decent-minded persons. The Medical Record has on several occasions called attention to this reprehensible custom. Paragraphs extolling the curative and remedial virtues of drugs for all complaints under the sun are a familiar feature of modern journalistic enterprise. In the ordinary everyday newspaper, so long as the bounds of good taste are not too flauntingly overstepped, and so long as the public is not gulled in too barefaced a manner into paying with good coin for useless and frequently really harmful nostrums, there can be no strong exception taken to this particular form of advertisement. After all, when a rational being has come to the years of discretion the presumption is that he or she should be a fairly competent judge of questions concerning health, and if such an individual prefers to patronize the venders of patent medicines rather than to seek the advice of a duly qualified medical practitioner, no restriction can be placed on this exercise of free will.

Many of these advertisements, however, do not fall within the category of either decency or utility and are unworthy of insertion by any self-respecting editor. Advertisements of this nature may be truly said to befoul the columns of the journal in which they are printed, and it would be matter for universal congratulation were measures enforced to compel their exclusion. It is bad enough when this nauseous literature is permitted a position in the sheets of lay journals, but the case is far and away worse when the readers of a paper devoted solely to religious subjects are *nolens volens* forced to have their eyesight offended by advertisements lauding the qualities of some unfailing remedy for impotence or an absolute specific for all female irregularities. Such a mingling of religion with affairs of so pre-eminently a mundane character is, to use the mildest language possible, in a high degree unseemly.

The question has also its comic side, and must appeal to any one endowed with but a faint sense of humor. Imagine an eloquent exposition of the Scriptures, contributed by the pen of some famous divine, while immediately underneath are to be read words of something to this effect: "Dr. B——, the celebrated specialist on complaints of women, can be consulted daily at his office, and will guarantee a complete cure to all suffering females in a very short time. N. B.: the drugs used are all of vegetable composition and are warranted not to injure the most delicate organization."

The resolution of *The Christian Herald* to bar altogether medical advertisements from its columns reflects the greatest credit on those in control of that journal, and its example should be promptly followed by other papers whose reading matter is of a denominational nature.

OSTEOPATHY IN GEORGIA.

The General Assembly of Georgia, at its recent session, passed a bill legalizing the practice of osteopathy in that State, and at the same time advertised "The American School of Osteopathy, of Kirksville, Missouri," concerning which school the Jefferson circuit court of Kentucky rendered so notable a decision a few weeks ago. Fortunately Georgia possesses in its governor a man endowed with both courage and common sense, and who, although strongly pressed to give his assent to the legalization of osteopathy, refused to do so, but on the contrary, exercised his power of veto.

For this action Governor Candler is entitled not only to the thanks of the medical profession, but also to the applause and respect of all good citizens. In his veto the governor pointed out that there is no need for the creation of another examining-board in Georgia. There are already three of these boards, and any graduate of any "lawfully chartered medical college" may go before either of them, present his diploma, and be examined. If he passes an examination satisfactory to the board, the members of which are selected because of their eminence in the profession and their skill in medical science, he is authorized to practise medicine anywhere in this State, and to apply any treatment he may deem best, including the methods of osteopathy. If he is not a graduate of a reputable medical college and cannot pass a satisfactory examination in the usual branches of medical education, he ought not to be licensed to engage in the practice of medicine.

This pronouncement places the whole question in a nutshell, and is a decision the justice of which can be gainsaid by no sane man. It will also be observed that no unfair discrimination is made against any particular school. The fact was proved to the hilt in the Kentucky suit referred to above, that the Kirksville School of Osteopathy in Missouri was not a reputable school in the proper acceptation of that term, and it is more than questionable whether the course of training considered sufficient there could impart to its graduates the medical knowledge necessary to satisfy the requirements of any of the three Georgia medical examining-boards. It would therefore be manifestly unjust to the medical profession as well as to the general public that incompetent men should be permitted to undertake the treatment of disease. However, the matter is not regarded by every one from this point of view. Indeed a prominent minister of the evangelistic persuasion contributed to the *Atlanta Journal* of December 30th a violent tirade, sharply criticising the public-spirited action of the governor and jeering at the medical profession for standing up for its rights. Some of the remarks of this clerical gentleman are gems of thought and diction. The following paragraph is an example of the manner in which a presumably cultured man may allow himself to be carried away by the force of his feelings:

"The little petty jealousies and envyings among doctors have made them the laughing-stock of intelligent people. A minister of the gospel can advertise in the papers a wonderful work of grace which led three thousand souls to Christ, but the very minute a medical doctor whispers it out that he has done something for suffering humanity he is jumped on for unprofessional conduct and outlawed by his profession. A lawyer can spurt and blow about himself, and his profession tolerates him at least, but wherever and whenever a doctor has spouted and spurted he has spouted and spurted himself to death."

The remainder of the Rev. Sam. T. Jones's discourse is conceived in the same prejudiced strain, which fact very considerably weakens the effect of his arguments. Probably he has a private grudge against the medical profession or is desirous of giving himself a cheap advertisement.

The rebuff to osteopathy in Georgia, following so close on the heels of the yet more decisive one in Kentucky, should go far toward strengthening the position of the medical profession throughout the length and breadth of the land. The methods employed by the emissaries of this "new science" are deserving of the severest reprobation, and must be met by the respectable medical practitioners with the most uncompromising vigor. The temporary check given to osteopathy in Georgia it is to be hoped will not lull its opponents into a state of false security.

News of the Week.

The Chester County Hospital at Westchester, Pa., has been bequeathed $2,500 by the will of the late Samuel Greenwood as a memorial to be known by his name.

Heroic Treatment for Corns.—A man in a Connecticut town—and an Adventist—having been troubled with corns, from which many remedies brought no relief, is reported to have removed the offending members by means of a chisel and mallet.

The Buncombe County (N. C.) Medical Society.—At the recent annual meeting of this society officers for the ensuing year were elected as follows: *President*, Dr. H. L. Bond; *Vice-President*, Dr. T. P. Cheesborough; *Treasurer*, Dr. C. G. Reynolds; *Recording Secretary*, Dr. J. T. Sevier; *Corresponding Secretary*, Dr. E. R. Morris.

The Famine in India.—The Indian officials estimate the cost to the government of the famine relief works, etc., to the end of March will be 40,000,000 rupees. About twenty-two million persons are now affected in British territory, and about twenty-seven million in the native states. About three million two hundred and fifty thousand persons are constantly receiving relief. Not only have the crops failed, but water is becoming very scarce, and many hundred head of cattle have perished.

Philadelphia Neurological Society.—At a stated meeting held January 22d, Dr. A. Ferree Witmer exhibited a case of left hemiplegia, in which, following an injury to the left wrist in consequence of a fall, a condition of over-extension of the proximal phalanges occurred, with flexion of the terminal phalanges. The peculiar claw-like hand resulting was thought to be accidental, and dependent upon the injury received. Dr. F. X. Dercum presented two cases of primary neurotic atrophy, one in a man and the other in a woman. In both the symptoms were present in the upper as well as the lower extremities, were of gradual development and of long standing. In the second case pain was present, while it was absent in the first. In the former no etiological factor could be ascertained, while in the latter there was a history of moderate indulgence in alcohol. Dr. D. J. McCarthy exhibited a case presenting trophic changes following injury of the supra-orbital nerve. The patient was a young woman who had been struck eight years previously upon the top of the head, to the right side of the middle line, suffering an incised wound of the scalp, with division of a branch of the supra-orbital nerve. In the sequence of this accident the outer two-thirds of the eyebrow and a portion of the hair on the corresponding side of the head became gray, while the soft tissues appeared firmer than normal and the bone was somewhat flattened; sweating was absent and sensibility was much impaired in the distribution of the affected nerve. Dr. McCarthy exhibited also a case of paræsthetic meralgia, in which this condition was present upon both sides of the body. It occurred in a man who wore a double truss for the support of bilateral herniæ, and the symptoms were more pronounced upon that side upon which the truss exerted the greater pressure. Dr. W. G. Spiller exhibited a man of advanced years presenting hysterical tremor resembling the tremor of paralysis agitans. Other members of the family had presented a similar tremor. The condition had been present for ten years, and the movements could be varied by suggestion. There was an absence of rigidity, of the characteristic facies, and of the sense of heat often present. In the discussion opinions were expressed that the tremor, while not hysterical, was perhaps one of heretofore unclassified character, and also that it was really that of paralysis agitans. Dr. A. A. Eshner reported a case of rhizomelic spondylosis. The patient was a man, twenty-four years old, who presented marked posterior convexity of the spine, with rigidity, and also stiffness and impaired mobility at the shoulder joints and the hip joints. In addition, the reflexes generally were exaggerated, while sensibility was unaltered. The condition was believed to be one of inflammatory hyperplasia of the vertebræ and their appendages, perhaps associated with meningitis or with inflammation or degeneration of the spinal cord itself. Dr. F. X. Dercum reported a case of cerebral diplegia of childhood with hemianæsthesia. The patient was a girl, upward of twenty years of age, who presented the ordinary phenomena of spastic diplegia dating from early life, but the hemianæsthesia was emphasized as an unusual condition. Dr. W. G. Spiller exhibited photographs and the brain of a boy with extreme contractures, and unilateral internal hydrocephalus. The case was one of cerebral spastic paralysis. Upon post-mortem examination, after the fluid had escaped from the greatly distended lateral ventricle, the corresponding hemisphere was found to be much smaller than its fellow, while the opposite half of the cerebellum likewise was diminished in size. Degenerative changes were found further in the right half of the spinal cord. The following officers were elected for the ensuing year: *President*, Dr. William G. Spiller; *Vice-Presidents*, Drs. J. K. Mitchell and F. S. Pearce; *Secretary*, Dr. A. A. Eshner; *Treasurer*, Dr. Guy Hinsdale.

Philadelphia County Medical Society.—At a stated meeting held January 24th, Dr. E. La Place reported a case of tetanus treated by the subdural injection of antitoxin, with exhibition of the patient. The symptoms of tetanus had developed in the sequence of a nail wound of the foot. An injection of 20 c.c. and subsequently 40 c.c. of tetanus antitoxin had been made beneath the dura mater, through a trephine opening in the parietal region. In addition, injections of carbolic acid were made, ♏v. being given on forty-eight occasions. Dr. Orville Horwitz presented a communication entitled "A Brief Account of a Few Surgical Cases of Unusual Interest." Among the cases reported was one of cyanosis of the arm, apparently due to vascular obstruction, and relieved by surgical intervention, although no obvious cause for the condition could be discovered; one of control of venous hemorrhage in the pelvis, occurring in the course of an operation for appendicitis, by the application of hæmostatic forceps, which were permitted to remain for a week, and another of similar application of forceps to the femoral vein for the control of hemorrhage due to division of the saphena vein at its junction with the femoral; one of incarcerated omental hernia, with beginning gangrene, but unattended with constitutional symptoms; one of rupture of an appendicular abscess into the sac of an inguinal hernia; one of chronic hæmatocele of the vaginal tunic of the testis following traumatism; one of fatal extirpation of spleen for enlargement of the organ; one of suprapubic cystotomy for the removal from the bladder of two hundred and eighty grains of white wax that was introduced into the urethra to prevent insemination; and one of intussusception in an adult, with recurrence requiring a second operation, and death from asthenia. Dr. T. J. Mays read a paper entitled "Notes on the Silver-Nitrate Injections in the Treatment of Phthisis." The treatment consisted of an anæsthetic injection of cocaine followed by the injection of ♏v. of a two-and-a-half-per-cent. solution of silver nitrate into the subcutaneous tissues of the neck over the pneumogastric nerve on the side corresponding to the seat of the disease. It was reported that in a large number of the cases thus treated weight improved, cough diminished, expectoration grew less, physical signs cleared up, night sweats disappeared, dyspnœa lessened, and general improvement took place. Drs. W. W. Moorhead and L. J. Hammond read a paper entitled "Report of Two Cases of Brain Abscess, One Multiple." Both terminated fatally in spite of operative intervention. A resolution was adopted protesting against the enactment of the Gallinger antivivisection bill before Congress.

Pathological Society of Philadelphia.—At a stated meeting on January 25th, a symposium upon typhoid fever was held. Dr. A. C. Abbott discussed the epidemiology. He pointed out that while ordinarily typhoid fever is an autumnal disease, in communities supplied by surface water or polluted subsoil water the greatest prevalence of the disease may occur at varying periods in the year. Dr. J. H. Musser discussed the value of clinical laboratory methods in diagnosis. He pointed out the importance of the Widal test, which can be depended upon in about ninety-eight per cent. of cases, and of the diazo reaction, which can be depended upon in perhaps ninety per cent. of cases; the significance of leucocytosis as indicating the occurrence of an inflammatory or suppurative complication; and the occasional presence of typhoid bacilli in the blood and their detection in the stools. Dr. A. O. J. Kelly summarized the results obtained at the German Hospital in the application of the Widal test. He pointed out the difficulties attending the employment of the dry method, particularly that in obtaining accurate dilution. Dr. Joseph McFarland stated that the personal equation is a not unimportant factor in the decision as to whether the reaction is present or not. Dr. H. W. Cattell reported the results of some observations made at the Woman's Hospital, and pointed out that in rare instances the presence of the Widal reaction might be utilized in distinguishing human from other varieties of blood. Dr. A. C. Abbott stated that in the bacteriological laboratory of the Philadelphia board of health the hæmoglobinometer is used for the purpose of securing a definite and constant and approximately accurate dilution of the blood. Dr. J. D. Steele, in reporting the results of observations made at the Presbyterian Hospital, stated that a satisfactory method of dilution consists in the use of the hæmocytometer, securing a dilution of 1 : 10 and then diluting this with an equal quantity of distilled water. Dr. R. C. Rosenberger reported the results of observations made in the Jefferson Medical College Hospital, showing a high proportion of positive results. Dr. N. B. Gwynn, of Baltimore, referred to the relative frequency with which typhoid bacilli, often in large numbers and in pure culture, are present in the urine, in association with symptoms referable to the urinary tract. A case was related in which typhoid bacilli had been found in the urine seven years previously, the patient recently again coming under observation with symptoms of cystitis and the presence of typhoid bacilli in the urine. Dr. Simon Flexner discussed the subject of typhoid septicæmia. He stated that occasionally the difficulty of making a diagnosis of typhoid fever is as great on post-mortem examination as during life, inasmuch as the disease is in a not inconsiderable number of instances unattended with intestinal lesions. In rare cases, further, the bacteria appear to have no special localization, and not merely circulate but also multiply in the blood, a condition that might be designated typhoid bacteræmia. Dr. T. G. Ashton read a paper entitled "The Duty of the Physician in Preventing the Dissemination of the Disease," in which he pointed out the importance of careful disinfection of all of the discharges from the typhoid patient in order to prevent the spread of the disease from the sick to the well. Dr. Joseph McFarland discussed the present outlook for the serum treatment. He was unable to make a favorable forecast, inasmuch as little is as yet known concerning the toxins of the disease, and there is reason to believe that so much serum would be required for the introduction of the necessary amount of antitoxin as to make such a mode of procedure, for the present at least, impracticable. Personal experiments in an endeavor to immunize horses and secure an effective antitoxin had proved unsuccessful.

Proposed Investigation of the Native Drug Plants of the United States.—One of the good works initiated by the Pan-American Medical Congress is the scientific investigation of the medicinal flora of each country on this continent. This has been carried out further in some countries than in this; in Mexico, for example, the investigation has been almost practically completed by the Instituto Médico Nacional. In his annual report the secretary of agriculture, Hon. James Wilson, states that the committee of the Pan-American Medical Congress for the United States has recently submitted to him a proposition to co-operate with the Department of Agriculture in a technical and statistical investigation and classification of our native drug plants. "By accepting this proposal," he says, "we shall secure, in a research of which we have long felt the need, the cordial assistance and support of an influential association of learned physicians; we shall encourage each of the other American nations, all of which are represented in the Pan-American Medical Congress, to proceed with a similar investigation of their own medical flora; we shall furnish a basis for the remunerative employment of much land and many people, and we shall stimulate the great growth and growing trade in drugs between the countries of North America and South America." He concludes by asking for an appropriation of $10,000 to enable the department to co-operate in this investigation.

Lehigh Valley (Pa.) Medical Association.—At the twelfth winter conversational meeting, held at Allentown on January 25th, papers were read by Dr. J. C. Biddle, of Fountain Spring; Dr. John B. Roberts and Dr. L. Boardman Reed, of Philadelphia; Dr. Edgar Moore Green, of Easton; Dr. A. H. Halberstadt, of Pottsville; Dr. Mary McCay Wenck, of Sunbury; Dr. Charles B. Knapp, of Wyoming; and Dr. Charles Miner, of Wilkesbarre.

Medical Practice in Honduras.—Dr. Francis T. B. Fest, of the Honduras army, writes, in answer to frequent requests for information regarding practice in that country, that every intending practitioner has to appear before a board of examiners to obtain a license. There are no openings; on the contrary, Dr. Fest says that he knows several gentlemen there who would like to hear of an opening somewhere else.

A Colossal Legacy.—Mme. Medvednikova, the widow of a wealthy merchant, died recently on her estate near Moscow, leaving 5,000,000 roubles (about $3,000,000) to charity. Of this sum 1,000,000 roubles is designated to establish a hospital for incurables in Moscow, 600,000 to build an asylum for idiots and epileptics in Moscow, 500,000 to build a hospital for the treatment of chronic diseases in Irkutsk, and smaller sums for various other institutions.

A Bill to Define the Status of Acting Assistant Surgeons in the Army.—Senator Platt, of New York, has introduced "A bill to issue warrants to acting assistant surgeons of the United States army who served as medical officers either in the late Civil War or the Spanish-American war or the Philippine rebellion." The bill provides "that all acting assistant surgeons of the United States navy who served as medical officers, agreeably to army regulations, either in the civil war or the Spanish-American war or the Philippine rebellion, and whose services were honorably terminated, and those acting assistant surgeons of the army who are still serving as medical officers, be issued warrants by the Secretary of War as acting assistant surgeons of the United States army in a similar manner with the warrants issued to the acting assistant surgeons of the United States navy by the Secretary of the Navy, the date of their warrants to be the date of their entry into the service of the United States as medical officers, and the date when their services as medical officers were or will be honorably terminated to be the date of their discharges from the service of the United States: Provided, that no back pay or allowance be made to any such acting assistant surgeon by virtue of this act." Acting assistant surgeons in the navy are commissioned by the Secretary of the Navy, and this bill only provides for similar treatment of acting assistant surgeons in the army.

The Gallant-Allis Ether Inhaler.—Dr. A. Ernest Gallant writes: "As the best means of acknowledging the many kind words of commendation, and in reply to numerous letters of inquiry, allow me to say that the Allis inhaler described in my article on 'Etherization' in the MEDICAL RECORD of December 30, 1899, is for sale by most surgical supply houses. The purchaser should insist on having the rubber cover not less than eight and a half inches deep. The threaded bandage should be cut out, and the gauze diaphragm adjusted, and half a yard of loosely bunched gauze inserted in the empty frame."

Antitoxin in Diphtheria.—Dr. J. Edward Herman writes: "In the table of mortality following tracheotomy in children under two years of age treated without antitoxin, appearing in my article in a recent issue of the MEDICAL RECORD, the rate printed did not represent the deaths but the recoveries. The corrected table should give seventy per cent. mortality for antitoxin-treated cases of tracheotomy in children two years of age and under, and fifty-nine per cent. mortality in the same class of cases which were treated without antitoxin."

An Antivivisection Accusation.—At the seventeenth annual meeting of the American Antivivisection Society, which was held in Philadelphia on January 25th, the corresponding secretary, Mrs. Richard P. White, gave us all away and exposed our wicked practices to the view of a horrified world. Among other temperate remarks this veracious lady is reported by the Philadelphia *Ledger* to have said that the "vivisection of human beings is the legitimate outcome of vivisection of animals. If the practice of torturing and dissecting dumb beasts be permitted to continue, it soon will become a menace to the human individual, not only to patients who lie in the wards of charity hospitals, but to citizens outside of institutions." Then having become thoroughly warmed up to her subject, she continued: "There is no longer any doubt as to the truth of the account that numbers of most atrocious and inhuman experiments have been and are being made upon poor patients in the hospitals of various European cities, and in at least one of our own States. That State is Massachusetts."

Sanatoria for Consumptives in New York State.—Drs. Enoch V. Stoddard and Stephen Smith and Mr. Harvey W. Putnam, constituting the committee on State sanatoria for consumptives, have made their report to the State board of charities. While they recognize that a State hospital in the Adirondacks would work great benefit, yet they do not think that that is the only way in which the disease can be successfully combated and eradicated. A better scheme, they think, would be to establish local sanatoria. This would work well for the poor, who object to going far away from home, especially if they have large families. Another important fact is that the cure will undoubtedly be of greater permanence when it is effected in the same climate in which the persons will always reside. The commissioners, therefore, recommend that the State board of charities advise for the relief of the poor suffering from tuberculosis such legislation as will lead to the establishment of a State system of hospitals on these lines. They say that if tuberculosis is officially recognized as a contagious affection, cases of which must be reported to the health authorities, the local boards of health could protect the community by establishing hospitals for the treatment of the disease to which sufferers could be removed.

Food Poisoning.—Dr. S. S. Bogert, of this city, reports two cases of ptomaine poisoning from eating veal, occurring twenty and twenty-four hours respectively after the ingestion of the meat. The vomiting and purging were severe and the prostration was marked, but both patients recovered.

A Reception in Honor of the "Maine."—The American women resident in Cape Town held a reception on January 23d at the Mount Nelson Hotel, at which Lady Churchill, the staff of the hospital ship *Maine*, the United States consul, and many other Americans were present.

Opposition to Female Nurses.—The London correspondent of the *Commercial Advertiser* says that, according to a private letter from Sir William MacCormac, there is excessive ill feeling between the army medical officers in South Africa and the female nurses at the base hospitals, some of the former urging the sole employment of male orderlies.

A Jewish Physician Honored in Russia.—During the Russo-Turkish war in 1877 an army surgeon, Dr. Grünkrug, distinguished himself for bravery on several occasions, and was rewarded by the bestowal of the cross of St. Vladimir, an order which carries with it promotion to the nobility. The Assembly of Nobility of Smolensk Province recently refused to inscribe Dr. Grünkrug's name on the list of noblemen on the ground that he is a Hebrew, but the College of Heralds reversed the decision, affirming that the physician was a Russian nobleman.

The Health of Havana.—According to the report of the health department of Havana, recently issued, there were, during the year 1899, 8,153 deaths in the city, or at the rate of about 36 per thousand, the estimated population being 225,000. The chief causes of death were: enteritis and dysentery, 1,163; malaria, 822; heart disease, 623; typhoid fever, 240; meningitis, 397; pneumonia, 322; marasmus, 173; cancer, 142; and yellow fever, 103. The mortality decreased progressively from January, with 1,260 deaths, to November, with 493; but in December the number increased to 534. There were in all 284 cases of yellow fever with 103 deaths. Up to August 1st there were but 7 deaths from this disease, and the great increase during the latter part of the year, which continued even through December, is attributed to the influx of unprotected immigrants from Spain and America. Of those who died 58 were Spaniards and 32 Americans. The death rate from yellow fever, in spite of this, was the lowest in the past ten years, the figures for the years 1890–98 being 327, 363, 362, 512, 418, 570, 1,540, 1,056, 162.

The Plague is spreading gradually throughout the islands of the Pacific, having already invaded Japan, Formosa, the Philippines, Australia, New Caledonia, and Hawaii, and not improbably other places from which reports are yet to come. In Honolulu up to January 17th there had been thirty-nine deaths, one of a white woman and the others among natives and Asiatics. The board of health has burned ten blocks of houses in the plague-infected section. A Red Cross society, formed by some of the ladies of Honolulu, has done most effective work, and the local physicians and clergymen have continually gone among the sick and dying, submitting to voluntary isolation in order to minister to the needs of the sick.—In Noumea, New Caledonia, the disease has prevailed since early in December. There were sixteen deaths during the first ten days following the development of the malady. Up to December 23d there had been no deaths among the whites, eight of whom had been infected, but nine Kanakas, two Japanese, and five Tonkinese had died of the disease. The part of the town where the infection first developed has been surrounded with a high galvanized iron fence seven hundred yards long. The principal business houses, official buildings, and the banking and shipping offices are guarded by posses of soldiers. Twenty buildings in the infected quarter of the town were demolished by the health authorities, but, despite all the precautions, the plague has continued to spread, the number of new cases averaging three daily.—At Sydney, New South Wales, general alarm is felt in consequence of the arrival of eleven passengers from Noumea, who landed before news of the plague's presence was received. Extraordinary precautions have been taken throughout Australia and strict quarantine is established. In the case of a wharf laborer in Sydney, who was attacked on January 24th, the inoculation was apparently traced to a flea bite.—In the Argentine Republic the plague is officially announced to exist at Buenos Ayres and Rosario, both of which ports have in consequence been closed.

The Tuberculin Test in Cattle.—An interesting experiment bearing upon the value of the tuberculin test, the details of which we find recorded in the Utica *Herald*, has been conducted at the Storrs Agricultural College in Connecticut. Four cows were subjected to the tuberculin test in March, 1896, and did not respond. In the next October they were tested again and all four responded. They were then placed in a light, airy stable, where it is estimated each cow had fifteen hundred cubic feet of space. They were tested again in January, 1897, and all four again responded. The following April another test brought responses from only two and the other two showed no reaction whatever. In July of the same year still another test was made, and there was no symptom indicating the presence of tuberculosis in any of the four. For two years their milk was fed to eight healthy calves, only one of which contracted the disease, and in that instance it appeared six months after it had stopped drinking the experimental milk, so that in all probability tuberculosis came from some other cause.

Antidote to Carbolic Acid.—A correspondent, referring to a paragraph on the treatment of carbolic-acid poisoning in a recent issue, recalls the use of cider vinegar or acetic acid in equivalent strength as an efficient antidote.

Influenza is prevalent to an alarming degree in Italy, Turin and Rome being especially afflicted, although few cities are free. There are estimated to be over thirty thousand persons ill with the disease in the peninsula, and the pope has ordered general prayers for the abatement of the epidemic. The disease prevails also in Spain, where in Barcelona alone one hundred and twenty-four deaths were attributed to it on January 26th.

Heat in Australia.—We suffer occasionally from warm summer days and nights in this part of the world, but the inhabitants of parts of Australia would be glad to put up with the worst that we have to endure. Almost every winter we have reports of excessive heat, and this year is no exception. It is stated that on New Year's Day in Melbourne the thermometer indicated 114° F. in the shade at five o'clock in the afternoon, and in the sun during the middle of the day it stood at 156°. There were five deaths from heat stroke.

An Insane Physician Kills a Child.—The newspapers recently reported a horrible case from an Iowa town. It is said that a physician of that State was in a friend's office when a ten-months-old child was brought in for examination. The doctor being called to attend an urgent case asked the visitor to examine the child. He did so and took the child in his arms, handling it so roughly that the parents protested. Suddenly he crushed the child's head between his hands, and then seized it by one foot and swung it around his head. The physician was apprehended and sent to the State hospital for the insane.

A State Home for the Aged.—A bill has been introduced into the New York legislature by Assemblyman Harburger, providing for the establishment of a home for the aged of both sexes, residents of New York, Kings, Queens, Suffolk, Richmond, Westchester, Nassau, and Rockland counties. Dependents over sixty years old shall be eligible for entrance. An appropriation of $100,000 is made for the purchase of land, erection and equipment of buildings, and temporary maintenance of the inmates.

Dr. D. A. Carmichael of the Marine-Hospital service, until recently in Honolulu, has been appointed chief quarantine officer at Manila, and is now on his way thither.

The Cuban Medical Congress.—The executive committee charged with the organization of the second Cuban Medical Congress has determined upon the following subjects for formal discussion: Local anthropology, medical topography and statistics, yellow fever, malaria, blackwater fever, chronic enteritis of warm countries, and atypical febrile states in infancy.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending January 27, 1900. January 24th.—Surgeon H. N. T. Harris ordered to the *Albany* via the *Prairie*. Passed Assistant Surgeon L. L. Von Wedekind ordered to duty on the *Richmond*. January 25th (changes by cable from Asiatic station).—Assistant Surgeon R. C. Holcomb detached from the *Solace* and ordered to the *Helena*.

The Late Dr. Mulhall.—The following resolutions were adopted at a recent meeting of the Beaumont Hospital Medical College of St. Louis:

"*Whereas*, In the loss we have sustained by the decease of our respected friend and esteemed associate, Dr. Joseph C. Mulhall, we, the faculty of the Beaumont Hospital Medical College, are desirous of testifying our respect for our departed member, and of expressing our earnest and sincere sympathy with the family in their great bereavement, and with the medical profession in the loss of one of their ablest and most enlightened fellow; therefore, be it

"*Resolved*, That we express our sincere condolence to the family of our deceased *confrère* in this, their hour of affliction.

"*Resolved*, That the Beaumont Hospital Medical College has lost one of its most valued and efficient teachers.

"*Resolved*, That the entire medical profession, of which our departed fellow was a shining light, has sustained an irreparable loss.

"*Resolved*, That these sentiments be duly inscribed in the records of the college, and that an engrossed copy thereof be presented to the family of the deceased."

Obituary Notes.—Dr. William S. House died at his home in Haverstraw, N. Y., on January 27th, at the age of sixty-two years. The cause of death was apoplexy. He was a graduate of the New York University Medical School in 1859.

Dr. L. H. Lawall died at Bethlehem, Pa., on January 24th, as the result of an apoplectic attack, at the age of seventy years. He was a graduate of the medical department of the University of Pennsylvania.

Dr. M. A. Booth, of Newport, Del., died at Washington, on January 24th, at the age of eighty-four years.

Dr. E. Eugene Weston died at West Pittston, Pa., at the age of forty-eight years. He was a graduate of the Baltimore Medical College.

Progress of Medical Science.

Journal of the American Medical Assoc., Jan. 27, 1900.

The Treatment of Aneurisms by Subcutaneous Gelatin Injections.—Thomas B. Futcher reports cases of aneurisms treated by gelatin, and draws the following conclusions from his experience: (1) In no case was the aneurism cured, although in one case of abdominal aneurism still under treatment there has been considerable diminution in size; (2) in seven cases out of nine there was an appreciable diminution of subjective symptoms; (3) it seems certain that the subcutaneous injection of gelatin does increase the coagulability of the blood; (4) the injections are frequently very painful; (5) the injections were often followed by rise of temperature, although Lancereaux states the contrary from his experience; (6) although in no case has a cure yet been obtained, the author is convinced that the method has some merit and deserves further trial.

Evidences that Bovine Tuberculosis is Communicable to Man by Direct Contact, or by Food Infection.—John A. Robison, after a wide review of the literature of this subject, concludes that we have not sufficient evidence of the intertransmission of bovine and human tuberculosis, yet we must admit that there may be danger in tuberculous milk. The danger is sufficient to call for laws insuring pure milk and food products on general principles, but until the exact danger attending the use of tuberculous milk can be proven, it is better to turn the attention of the public to other, and better proven, exciting causes of the disease.

An Intestinal Suture.—Raymond Custer Turck presents diagrams of a modified form of the Halsted suture. The writer says that this new suture might properly be called a "lock stitch," because each loop is locked through the adjacent ones, and stitch leakage is rendered impossible. An exhaustive series of experiments with this stitch are being conducted at the Post-Graduate Laboratory of Anatomy and Operative Surgery, the results of which will be given later and at length.

Contagion in Leprosy as Observed in San Francisco.—Douglas W. Montgomery says that from his observations the Pacific coast is not merely a temporary abiding-place for a few lepers who have come by accident, but that the disease may be contracted there, thus rendering this part of the United States a veritable leper focus. The writer draws these deductions from cases of leprosy in aliens occurring in his own experience, and adds that the remedy must be in the segregation or deportation of the lepers already there and the more stringent examination of immigrants from leper countries.

Probable Brain Tumor with Recovery.—In this case, reported by W. A. Jones, although the diagnosis was a matter of extreme difficulty, the general symptoms of headache, vertigo, vomiting, ocular palsy, left-sided paralysis, with ankle-clonus and increased knee-jerk, subnormal temperature and pulse, together with extreme irritability, all pointed to a tumor as the probable explanation. The treatment was mainly experimental, consisting in calomel and saline for the bowels, morphine for the pain, hypodermics of strychnine for the slow and irregular pulse, and iodides by inunction. After a slow convalescence recovery was complete.

Influenza.—G. E. Crawford, discussing influenza, says that every case should be regarded as serious and the patient put to bed until active symptoms disappear. The following prescription has been of service to the writer:

℞ Acetanilid	gr. ij.
Caffeine	gr. ss.
Camphor monobromide	gr. i.
Capsicum	gr. ss.

Some Questions Relative to the Diagnosis of Anæsthetic Leprosy.—J. G. McDougal discusses the case of two sisters, natives of Ohio, who manifested appearances of anæsthetic leprosy. Although the true nature of these cases has been questioned, the author does not think that any other diagnosis thus far advanced, can be considered tenable.

Syphilis from Dental Instruments.—William L. Baum quotes several cases, and says that the dentist should personally supervise the disinfection of instruments by boiling, and immersion in formalin or creolin solutions.

May We Not Frequently do Great Harm, Rather than Any Good, by Office Treatment of Female Generative Organs?—Milo Buel Ward thinks that this question may be answered affirmatively in a great majority of cases.

Syphilis of the Nervous System and the Use and Abuse of Mercury and Iodine in its Treatment.—By William M. Leszynsky. See MEDICAL RECORD, vol. lvii., p. 38.

Physical Standard of National Guardsmen.—By Gen. J. Francis Calef.

New York Medical Journal, January 27, 1900.

Flexion or Bent-Knee Marching.—E. H. Bradford analyzes and illustrates by diagrams the ordinary straight-leg gait of the civilian and of the conventional military parade, and shows its inferiority to the bent-knee gait when it comes to the matter of getting soldiers or pedestrians rapidly over uneven ground. This latter resembles a run except that both feet are never off the ground at the same time. It is described as follows: "The knees must be always bent; the feet lifted no higher than necessary to clear the inequalities of the ground; the advancing foot must be placed flat on the ground, the step being made neither by the toe nor by the heel. The footfall should be noiseless, and the steps at first short and frequent. The body must lean well forward, the back must be straight and the head erect, the chest open and shoulders low."

Staphylitis and Elongated Uvula.—T. W. Kilmer describes acute and chronic inflammation and elongation of the uvula together with the technics of uvulotomy. Special stress is laid upon the necessity of severing the offending portion with one cut of the scissors, as a smooth surface is the ideal one in surgery of the nose and throat.

Remarks on Intranasal Operations.—For the removal of spurs when small and anterior, the use of the annular knife is recommended. For intranasal splints the Barnays sponge is preferred. For splints embracing the full width of the septum a special form is devised, consisting of two hollow plates, one for each side, connected by a spring. The hollow plates carry an additional plate so arranged that after introduction the posterior end is elevated after the shape of a fan.

The Study of Inhibition.—The following theory of inhibition is proposed by J. Y. Gonzales: Every vital organ exhibiting inhibitory phenomena constantly receives two currents of nervous vibrations in opposite directions, and as these are partly neutralized there remains a resultant working in the direction of functional activity as ordinarily manifested by the organs.

A Treatment for Acute Serous Synovitis Permitting of Joint Functions.—P. Hoffmann extols the compression treatment, which consists of filling all the depressions about the joint with cotton and the subsequent application of strips of rubber plaster in such a way as completely to encircle the joint and several inches of the limb above and below it so as to make firm and equable compression.

Pony, Montana, as a Resort for Cases of Pulmonary Tuberculosis.—The advantages of the locality are set forth by J. C. Schapps. Patients often do better here, he says, than in Colorado. The winters are cold and dry, the altitude is sufficient, and sunshine is prevalent.

Antitoxin Results and Definitions.—A. Rupp does not believe that all the problems of diphtheria have been solved, and again expresses his doubts regarding the value of antitoxin in this disease.

Clinical Memoranda on Otitis Media Chronica Suppurativa.—J. F. Oaks summarizes the usual therapeutic measures in the different stages of this affection.

Medical News, January 27, 1900.

Experimental Researches on the Effects of Increased Barometric Pressure and of Foreign Bodies in the Pharynx, Œsophagus, Trachea, and Larynx.—George W. Crile gives a description of his experiments, with tracings showing the changes in blood pressure. He says that experiments with increased barometric pressure, as well as those on drowning, show that a sufficient increase in the intrapulmonary pressure may produce a collapse of the circulation. It robs the left heart directly of blood, and therefore causes a greater collapse than can be produced by severing either the superior or the inferior vena cava alone. The symptoms produced by foreign bodies of considerable size lodged in the pharynx and certain portions of the œsophagus closely resemble those caused by foreign bodies in certain parts of the respiratory tract. Choking produces symptoms of reflex inhibition, partly through the superior laryngeal and partly through the trunk of the vagus. In a given case of threatened asphyxia, if operation is to be undertaken for dislodgment of a foreign body, it would be well to give a preliminary dose of atropine to prevent a great collapse or possible death.

Hernia in Pregnancy and Pregnancy in Hernia, with Note on Umbilical Hernia.—Thomas H. Manley's experience has been that groin ruptures, generally, are neither produced nor aggravated by child-bearing, but navel ruptures often greatly augment in volume during pregnancy, if they are not sometimes produced by it, and with repeated confinements may attain enormous proportions. Cases are reported of the impregnation of the uterus lodged in the sac of an umbilical, ventral, femoral, or inguinal hernia. Umbilical herniæ of large size are rarely seen except in child-bearing women. There is no evidence that the gravid uterus is ever a cause of strangulation.

Pruritus Ani.—By J. P. Tuttle. See MEDICAL RECORD, vol. lvi., p. 66.

The Great Drainage Canal at Chicago.—J. A. Stewart describes this canal, which is an open channel one hundred and sixty feet wide at the bottom and thirty-eight feet deep. Its purpose is to unite the south branch of the Chicago River to the Desplaines at Lockport, Ill., whence it will flow to the Mississippi River.

Boston Medical and Surgical Journal, January 25, 1900.

The Value of X-Ray Examinations in the Less Frequent Diseases of the Chest, Illustrated by their Use in Those Cases in which Aneurism is Present or Suspected.—Francis H. Williams concludes that *x*-ray examinations should be made with both fluorescent screen and *x*-ray photograph. Normal outlines in the upper part of the chest give us the best assurance that an aneurism of the aorta is not present. *X*-ray examinations enable us to determine the extent of an existing aneurism, whether or not it is increasing, and in some cases to make a diagnosis before there are physical signs.

Sixteen Years' Experience in Food and Drug Inspection.—Samuel W. Abbott reports the work of the State board of health of Massachusetts in this line, and urges the general establishment of such work. States that have no such system of inspection, he says, have an inferior food supply, so far as relates to articles liable to adulteration. The system is now in force in almost every large city on the continent of Europe as well as in Great Britain.

A Sterilizer and Equipment for Confinement Cases.—Frank A. Higgins describes a convenient outfit of his devising to be carried in the physician's obstetric bag.

On the High Operation for Diseases within the Scrotum.—J. G. Mumford believes that this useful procedure may be employed in most cases of disease in this region.

Ptomain Poisoning.—W. P. Coues reports a severe case, in which treatment by heat, strychnine gr. $\frac{1}{15}$, tincture of digitalis ♏ xv., and morphine gr. $\frac{1}{8}$ was followed by recovery.

A Rhode Island Philosopher (Elisha Bartlett).—By William Osler. Concluded from a previous number.

Philadelphia Medical Journal, January 27, 1900.

A Case of Multilocular Pseudo-Mucinous Cystadenoma of the Right Ovary Associated with Pronounced Symptoms of Diabetes.—Henry D. Beyea reports a case of this description occurring in a woman fifty-three years of age. The tumor was removed by operation; the patient recovered, and the glycosuria and other diabetic symptoms disappeared.

Athetosis and Kindred Affections.—Frank Fischer reports a case of athetosis in a boy, aged twelve years, following an attack of rheumatism. He discusses the nature of athetosis, chorea, and epilepsy, and suggests that in these affections the lesion is frequently located in the sensory tract, and that the disorders are therefore largely reflex.

Diet as a Method of Diagnosis.—C. D. Spivak advocates putting patients with gastro-enteric troubles on special diets for a day or two at a time, noting the symptoms felt while on each.

New Staining-Forceps.—F. J. Kalteyer describes and pictures an ingenious forceps devised by himself. It is made of nickel-plated steel wire, and by means of it a cover glass can be held immersed in staining fluid in a Stender dish, the forceps supporting itself on the table.

Medical Societies in this Country Founded Prior to the Year 1787.—Francis R. Packard presents an historical sketch of nine medical societies founded before the College of Physicians of Philadelphia. Of these, three—the New Jersey, the Massachusetts, and the New Haven medical societies—still exist.

Selections from the Lane Lectures.—Clifford Allbutt describes in this lecture, delivered in San Francisco in 1898, the physics of the heart.

Medical Press and Circular, January 17, 1900.

Excision of the Vesiculæ Seminales for Tuberculous Disease.—Mansell Moullin gives two cases in which he has removed the vesicles, dividing the vas deferens as high up as possible. He had previously removed one seminal vesicle in another patient for chronic inflammation following gonorrhœa. He employs the Zuckerkandl incision, slightly modified. The vesicles were found filled with caseous masses. Few instances are recorded in literature and none in that of England. The patient is placed in the lithotomy position, but lying upon the side. The operation is useless when the disease has extended beyond the vesiculæ.

Notes on Recent Cases of Enteroptosis.—A. A. Symons Eccles relates four out of the twenty-two histories recorded in 1899. In all there were neurasthenic symptoms and failing health, in some depression, gloom, and prostration. One was a typical instance of Glénard's disease with gastritis, dyspepsia, enterostenosis, nervous and muscular prostration. In all there was eructation upon taking food and generally constipation with flatulent distention. Two were treated by rest, uplifting diet, and manipulation with subsequent wearing of the belt. In the others a belt was ordered which gave relief from the local discomfort. Diagrams are given of the stomach's position.

Tabetic Ophthalmoplegia.—Leonard Guthrie records the clinical features of a case and draws attention to the frequent occurrence of paralysis of ocular muscles as a pre-ataxic symptom. The paralysis is frequently cured by the ophthalmic surgeon or spontaneously subsides, and perhaps years afterward other signs of tabes appear.

Diphtheria.—By William R. Smith, the second of the Harben lectures.

The Lancet, January 20, 1900.

On the Feasibility of Carrying Out the Open-Air Treatment of Consumption at the Patient's Home.—T. A. Somerville and E. S. Yonge report the case of a man aged thirty years with acute tuberculous broncho-pneumonia, who was unable to leave home and so was put on creosote, maltine, and an inhalant, and advised to spend as much time as possible in the open air near his own house. Subsequently, over-feeding and graduated exercise were added to the régime. On one day in a week he was allowed to go to his office for a few hours. On other days he spent seven hours out-doors or in wet weather sat in a sheltered summer-house facing the south. The windows of his sitting-room and bed-room were kept widely open. Under this mode of living he gradually improved, and in two months appeared perfectly well. The writers believe that this plan of treatment is worthy of a much wider application than it has yet received.

On Some Points in the Natural History of Uterine Fibroids.—F. H. Champneys answers four questions: 1. Frequency. Of 40,615 gynæcological out-patients, fibroids were diagnosed and treated in two and one-half per cent.; of 5,875 in-patients, in nine and four-tenths per cent. 2. Their symptoms are due to pressure and weight, bleeding, pain, and uterine catarrh. 3. The mortality from operation is seventeen per cent., while that apart from operation is represented by the figures 0.000138 per cent.; in other words, deaths from fibroids apart from operation are excessively rare. 4. He discusses the ethics of operations, basing his statistics in this and other respects on the records of St. Bartholomew's Hospital.

Tubercle Bacilli in Milk, Butter, and Margarin.—H. E. Annett's experiments show that bacilli are found in samples of milk in English cities in from three to thirty per cent., the test being inoculability in animals. They have been found in butter by other observers in from ten to forty-seven per cent., but there is some doubt whether the germs described by these other observers have been the true bacilli of Koch. Tubercle bacilli keep their virulence in butter for twelve days. Out of twenty-eight samples of margarin, only one proved to contain the germ of true tuberculosis.

Case of Perforated Gastric Ulcer on the Posterior Surface of the Stomach; Operation, Recovery.—The patient, a woman aged thirty years, was seen by S. Davy and operated upon by F. Eve. Symptoms which had occurred suddenly were those of collapse. In six or seven hours she had rallied sufficiently to justify operation. The perforation was on the posterior surface close to the lesser curvature and attachment of the lesser omentum.

A Note on Some Further Experience of Operations under Local Analgesia Produced by Eucaine B.—A. E. Barker enumerates fifty-three various operations done under the conditions specified. He says that at first the surgeon suffers from the feeling that he may be causing the patient pain, and that makes him hesitate. Practice in the method, however, soon removes this.

Tetanus following Nephropexy.—H. Thompson operated on a woman aged forty-seven years with a loose right kidney. On the eighth day initial symptoms of tetanus set in, gradually increased, and caused death on the fourteenth day. No antitoxin was used. The author discusses the possible relation of mental shock to the affection.

Some Facts Gathered from Experience Respecting Miscible Black Carbolic Disinfecting Fluid and Carbolic Disinfecting Powder.—F. W. Alexander calls attention to the varying results of analyses of these compounds and the confusion caused thereby. He advocates the necessity of adopting uniform standards of testing.

Plague in Relation to Singapore.—M. F. Simon gives some statistics from the official health records of that city. Details are given in brief of some ten individual cases.

Results which Have Been Obtained by Antityphoid Inoculations.—By A. E. Wright. See MEDICAL RECORD, vol. lvii., p. 199.

British Medical Journal, January 20, 1900.

Results which Have Been Obtained by the Antityphoid Inoculations.—A. E. Wright and W. B. Leishman summarize the more important results which have been obtained up to date by the application of the antityphoid inoculations which were inaugurated at Netley in July, 1896, among the troops in the Indian service. The men under observation numbered 11,295, of whom 2,835 had been inoculated. The number of cases among the inoculated was 27, or 0.95 per cent., and among the uninoculated 213, or 2.5 per cent. The number of deaths was 5, or 0.2 per cent., among the inoculated, and 23, or 0.34 per cent., among the unprotected. Assuming that these figures would be the same relatively if applied to the entire army, the authors estimate that general inoculation would effect a saving of one thousand cases of typhoid fever and nearly two hundred lives. A detailed account is given of the methods which had been employed in the preparation of the vaccine.

The Bromide Sleep; A New Departure in the Treatment of Acute Mania.—Neil Macleod presents notes of cases he has treated by means of "the bromide sleep," which he explains to mean a condition induced by large doses of bromide lasting from five to nine days, in which the subject sleeps day and night and from which he cannot be roused. The writer claims that during this period the higher nerve centres are rested to an extent that cannot be reached in any other way. In his experiment with nine cases the results were satisfactory with one exception, a case of morphine and cocaine habit, in which a double pneumonia supervened with fatal result.

The Insane and their Treatment.—J. B. Spence contrasts the present humane and scientific treatment of the insane with older methods. He also touches upon the duty which the general practitioner owes to the insane in the early identification of functional and curable phases of mental disease. In this connection the writer deprecates the consignment to asylums of those cases of drink madness which in many instances might just as well be cared for elsewhere, thus avoiding the stigma which is incurred, in the eyes of the public, by residence in an insane asylum of however short duration.

A Case in which Three Hundred Grains of Sulphonal Were Taken in Two Doses.—R. Percy Smith reports this case. The patient was promptly treated by apomorphine hypodermically and a purgative by the mouth, and no toxic effects of the sulphonal followed except drowsiness. This case illustrates the ease with which the laity can obtain large doses of drugs which are toxic if taken in sufficient quantities.

Case of Brain Tumor Simulating Myxœdema.—David Sommerville reports this case, in which all the symptoms pointed to myxœdema. There was no evidence of syphilis, and the patient improved somewhat under thyroid treatment. The necropsy revealed a large glioma in the right occipital lobe. The thyroid gland was normal. The author points out the uselessness of the thyroid extract as a therapeutic test.

A Criticism of the Mechanical Hypothesis of the Origin of Carcinoma.—Samuel G. Shattock exhibits a specimen of "spontaneous" carcinoma of the uterus in a rabbit, which he thinks argues against the experiment upon which Lambert Lack bases his theory of the mechanical origin of cancer.

Spasmodic Closure of the Larynx during the Administration of Ether.—W. J. McCardie reports a case illustrating the fact that some patients with compensated mitral stenosis are unable to take ether as an anæsthetic.

Formic Acid and the Inhalation of Formalin.—J. Lardner Green reports good results from this treatment as a preparation for and aid to the open-air treatment of phthisis.

A Case of Jacksonian Epilepsy Cured by Operation.—This case is reported by H. Drinkwater as being of interest because the patient is now, more than four and a half years since operation, in perfect health and working regularly.

A Case of Imperforate Vagina. — Stephen M. Laurence reports this case, in which, with an apparently complete absence of uterus and vagina, there is yet a perfectly normal development of vulva, mons veneris, and mammæ, leading to the supposition that a light thickening felt at the sides may possibly be ovaries.

Twin Pregnancy with Central Placenta Prævia.—Collingwood Fenwick reports a case of this condition occurring in a twin pregnancy. There were two placentæ, one lying across the outlet and the other attached to the lower segment of the uterus.

Imperforate Anus.—F. Ormrod reports a case of imperforate anus in a male child. Fecal matter was passed through the urethra. The bowel was cut into with some difficulty, and the child made a good recovery.

Ulcer of the Stomach.—A clinical lecture by Robert Saundby.

Berliner klinische Wochenschrift, January 8, 1900.

Contribution to the Pathology of Lead Paralysis.—M. Bernhardt describes the various types of this affection as set forth by different observers since the time of Duchenne, and then records two interesting cases of isolated paralysis of the small muscles of the hand occurring in two painters of the ages of nineteen and forty-one years respectively. In both instances the extensors of the hand and finger, which generally are most constantly and the earliest affected, remained intact throughout. M. Bernhardt regards this grouping of symptoms as very unusual.

Psoriasis and Glycosuria.—F. Nagelschmidt alludes to the rare association of these two affections and gives an account of some experiments made to determine whether psoriasis patients are more disposed to alimentary glycosuria than are healthy persons. Out of twenty-five persons with the skin affection, eight showed evidences of alimentary glycosuria when fed on grape sugar, a certain quantity being given each morning. But the author admits that persons with other cutaneous affections are also liable to this form of glycosuria, and is not willing to admit that there is any special predilection thereto among patients with psoriasis.

A New Method of Treating Syphilis by Inhalation.—R. Kutner has used with success the following procedure: Mercurial ointment is carefully rubbed over the inside of a box by means of a special device which the patient can use himself. The latter breathes the vapor of mercury given off from the rubbed surface, by means of a mask attached to a tube leading from the box. A heating device can be employed to keep the interior of the box at the proper temperature for the volatilization of the mercury.

Leprosy Hospitals Past and Present.—M. Kirchner alludes to the various institutions throughout the world, and describes a model house for the care of this disease, situated at Memel in Germany.

Munchener medicinische Wochenschrift, Jan. 2, 1900.

Clinical Experiments in Regard to the Influence of Irrigation of the Vagina during Labor on the Puerperium.—Krönig submits the following statistics which are based upon the results of his experiments. Of 515 patients in whom irrigation was performed the rectal temperature was above 38° C. in the puerperium in 235, or 45.6 per cent.; above 38.5° in 121, or 23.5 per cent.; 39° in 75, or 14.5 per cent.; 39.5° in 41, or 7.96 per cent.; and 40° in 17, or 3.3 per cent. One patient died of sepsis, giving a mortality of 0.19 per cent. Of 465 patients in whom irrigation was not carried out the rectal temperature was above 38° C. in the puerperium in 177, or 38 per cent.; 38.5° in 86, or 18 per cent.; 39° in 45, or 9.6 per cent.; 39.5° in 25, or 5.1 per cent.; and 40° in 12, or 2.5 per cent. One patient died of sepsis—a mortality of 0.21 per cent.

A Peculiar Influenzal Eruption on the Skin.—Rieger describes a skin eruption which was followed by marked swelling of the head and face, and which he attributed to the retained poison of influenza. The ordinary symptoms of influenza were present in the patients, and Rieger, suffering from the malady himself, concludes that the organism though an energetic reaction sought to destroy the stored-up poison, and through a kind of scalding drowned the poison in the heated exudate, for after subsidence of the swelling perfect health was restored. Other analogous cases have been noted, but according to Rieger have been incorrectly diagnosed as erysipelas.

The Influence of Fluorescent Material on Infusoria.—H. v. Tappeiner states that light causes acridin, phenylacridin, eosin, and quinine in solution to have a very baneful influence on paramecia, while in the dark these substances are not at all, or at least very slightly, poisonous. This injurious effect is dependent on the excitation of fluorescence.

Diagnosis and Therapy of Suppuration of the Eyes in the New-Born.—Von Ammon gives the results of the bacterial examination of many affected eyes, and finds that gonorrhœal infection at birth is relatively infrequent compared to the later infection. Therapy in the beginning of eye suppuration must not be of an irritating nature.

A New Guaiacol Preparation.—Alfred Einhorn calls this new preparation the hydrochlorate of diethyl-glycocol-guaiacol. It is easily soluble, and is split up into guaiacol in the organism. It is entirely non-poisonous, is non-corrosive, is easily absorbed, is anæsthetic, antiseptic, and deodorant.

Blue-Blindness in Contracted Kidney.—C. Gerhardt gives some interesting observations on this subject. In the cases he has noted all blue objects appeared black.

Wiener klinische Rundschau, January 6, 1900.

Contribution to the Knowledge of Pemphigus Vegetans.—Neumann states that this affection used to be regarded as syphilis. The prognosis is always gloomy. In Neumann's first cases the average duration of the disease before death was three-quarters of a year. Kaposi and Hebra have reported cases of ten years' duration. As to treatment, tincture of iodine and trichloride of iodine have given temporary relief. The best results are obtained from surgical treatment because by excision of the growths the exuding surface is diminished and the loss of the body juices decreased.

A Rare Combination of a Bullous Eruption of the Skin (Epidermolysis Bullosa) with Hydrops Hypostrophos.—Max Wilheim gives Schlesinger's characterization of this affection as a recurrent, œdematous, often extensive swelling of the skin, mucous membranes, and other parts. It is not inflammatory, neither is it painful. The etiology is not settled. Quincke thinks it depends upon an angioneurosis. It may be that auto-intoxication plays an important rôle in this disease. An interesting feature in a case quoted is that an acute nervous œdema is established by the influence of a local injury.

Mathematical Talent.—P. J. Möbius divides mathematical talent into four grades. In the lowest he places most women and not a few men. The second he designates as normal and includes in that those who can understand what is taught in high schools. In the third belong engineers, seafaring men, and physicists. The fourth comprises those who can grasp the whole subject of mathematics. He also adds that a fifth class might be made for mathematical geniuses—those who contribute original work to the subject. In examination of the brains of mathematicians an excessive development of the convolutions has been found, but the skull has never been described.

Wiener klinische Wochenschrift, January 4, 1900.

The Clinical Significance of a Displaced Kidney.—J. Hochenegg reports a case operated on by him of a kidney which was found in the pelvic cavity. The patient, a woman fifty-two years of age, had for years suffered from constipation with its well-known train of evils. The nervous expression of her trouble had grown so severe that the symptoms were hysterical. It was found necessary to extirpate the kidney, which was abnormally formed, being round in shape like a cake, still retaining the embryological lobes, and having a hilus which looked forward. Otherwise it was normal. This was undoubtedly a congenital malposition having no connection with the wandering kidney. Although, as a rule, there are no special clinical symptoms in this affection, when they do occur it is from pressure on neighboring organs, as in this case on the intestine. Anuria from compression of the ureter has been reported, also different forms of nephritis. The progress of labor has been affected—one case of rupture of the uterus being recorded.

Some Unusual Concretions in the Human Urinary System.—O. Zuckerkandl states that urethral stones are infrequent as compared with bladder concretions. He describes three of the former, giving illustrations. The first was almost as large as a cherry and ovoid. The second, walnut-shaped, measured 28 mm. by 12 mm. The third was like a bean. He next presents three preputial stones. Two were flat ovoid and the third was fashioned with two facets. They were the size of grape-seeds. Three more concretions were ureteral and were each composed of two parts united by a very narrow neck.

Contribution to the Knowledge of the Origin of Urinary Casts.—Ernst v. Czyhlarz believes that many hyaline casts are found in urine with no albumin; that granular casts are composed chiefly of detritus, and that desquamation of epithelium occurs mostly in the collecting tubules.

A New Cystoscope for Catheterization of the Ureters.—M. Schlifka describes, with an illustration, a new cystoscope which he thinks will prove more convenient than earlier instruments.

French Journals.

Bilateral Intermittent Ranula.—André says the exact anatomical origin of ranula has not been definitely established in spite of the great amount of attention given the subject. He relates an observation on a woman, twenty-two years of age, in which a double or bilateral ranula of intermittent character took its origin in the dilated canal of Wharton. This is a rare condition which has not been mentioned in books. The permeable orifices on both sides made it possible to enter into a fairly large pouch, but in spite of the permeability of the duct the fluid contents reached a point interfering with deglutition and phonation. To effect a cure the tumor is to be emptied every morning by dilating the canal with a lead probe of gradually increasing size.—*Le Bulletin Médical*, January 10, 1900.

Pott's Disease of the Cervical Region with Brachial Paraplegia.—Broca observed, for several months, a boy, six years old, with cervical Pott's disease and Goll's paraplegia. After a few months he had difficulty in the use of the left arm, and paralysis quickly followed. Continuous extension was carried out, both to the hip and lower extremities, and marked amelioration followed. Pain came on early, extending to the arm even before there was stiffness of the neck. It was pointed out that, contrary to the rule, there were no subsequent motor disturbances in the lower limbs.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, January 11, 1900.

Cinnamate of Sodium in Pulmonary Tuberculosis.—A. Mann treats tuberculosis by the intravenous injection of an aqueous solution of cinnamate of sodium which, he says, can be used without the least danger. An increase of leucocytes is to be made out shortly after the injection; granulations begin to form and the necrosed tuberculous masses are absorbed. A solution of one to five per cent. of an active substance is used. One or two minims of the weaker solution is injected and gradually increased in strength, being repeated every forty-eight hours. The median basilic or cephalic vein is chosen for the injection, and an antiseptic bandage is applied.—*Journal de Médecine de Paris*, January 14, 1900.

Expression of the Fœtus by the Abdominal Method.—G. Keim describes his method of aiding the expulsion of the child by manual pressure causing uterine contraction and expression. He confines himself to the delivery of the fœtus at or near term. He finds that these manipulations are without danger for the fœtus, and that they do not cause the phenomena of asphyxia or fatal compression. There is, however, a possibility of meningeal or medullary hemorrhage in certain cases. These facts, added to the harmlessness to the mother and the possibility of its application without asepsis, make it valuable, but it is not intended to exclude entirely the use of forceps and other operative measures.—*La Presse Médicale*, January 13, 1900.

The Cardiac Complications during Convalescence from Typhoid Fever.—J. Mollard has made fifty-two observations bearing on this question, and concludes that in four-fifths of the cases cardiac troubles are found, in about one-half of which there is a true syndrome having the following features: (1) Effacement or attenuation of the precordial impulse, slight displacement of the apex in cases in which it can be localized; (2) disturbances of rhythm; tachycardia, embryocardia, arrhythmia; (3) change in the sounds of the heart, medio-cardiac systolic souffle, *bruit de galop*, enfeeblement of the first sound or both sounds together.—*La Presse Médicale*, January 10, 1900.

Periodical Vomiting in Infancy and its Treatment.—R. Romme says that periodical vomiting is observed almost exclusively in large children in whose history, either hereditary or personal, a neuro-arthritic source is found. This gives us a therapeutical indication of the first order and our efforts must be directed toward the diathesis itself. The child's temperament must be changed by hygiene, proper alimentation, etc. Constipation must be obviated, and an occasional purgative be given containing jalap and scammony. In the attack itself there should be freedom from all excitement, and a very rigid diet.—*La Presse Médicale*, January 10, 1900.

The Treatment of Psoriasis.—Hallopeau and Leredde review the internal and external treatment of psoriasis. The external is considered the most important and quickest way of ridding the surface of scaly lesions. After this come chrysarobic acid, pyrogallic acid, eugallol, anthrarobin, oil of cade, tar, calomel, and beta-naphthol. Among the water cures Lonesche, Uriage, and Bourboule are recommended. Sulphur baths are given as an after-treatment.—*Bulletin Général de Thérapeutique*, January 8, 1900.

The Technique of Total Abdominal Hysterectomy in Suppuration of the Adnexa.—J. L. Faure says it is better to take away the uterus at the same time that the adnexa are removed, because it is always infected and can serve only to keep up pain and various troubles. The abdominal route is preferred for every case attended with severe suppuration and those that are acute and virulent. He goes on to describe his technique.—*Journal des Praticiens*, January 13, 1900.

The Mechanical Treatment of Sciatica.—Paul Frétin gives, with illustrative drawings, the technique he employs, including frictions, massage, vibrations of the nerve trunk itself, passive extension of the sciatic nerve, and gymnastic movements of the lower extremities and trunk.—*Journal de Médecine de Paris*, January 14, 1900.

The Reduction of Fractures by the Aid of the Radiograph.—Th. Tuffier gives, with numerous drawings, the employment of the *x*-rays before, during, and after the treatment of various fractures, especially of the arm and about the shoulder.—*La Presse Médicale*, January 10, 1900.

Revue de Chirurgie, January 10, 1900.

Endothelioma of the Bones.—Paul Berger reports a case of tumor of the humerus with spontaneous fracture; and disarticulation of the shoulder, performed by the author to remove the growth, was shortly followed by the appearance of tumors in the orbital and frontal region, on the thigh with fracture of the femur, and in the spine. A histological examination of the tumor showed that it could not be classed with the epitheliomata. The form of the cells and the arrangement of the capillaries excluded sarcomata. It was evidently of a class of neoplasms which have been called endotheliomata or peritheliomata.

The Surgical Treatment of Genital Tuberculosis in Men.—L. Longuet considers that castration as an operation of predilection is a mistake, as is preservation of the organ by abstention. The truth lies between these two extremes, and the proper treatment consists in a variety of operations, adapted to individual cases. In some instances a portion of the organ must be removed, in others the whole, but there must be conservatism in the surgical procedures.

Accidents due to Epileptic Attacks.—Charles Féré writes of the disastrous results of the tonic contractions of muscles during an epileptic attack which are liable to occur. Such are asphyxia from spasm of the neck and chest muscles, rupture of heart, liver, or diaphragm, section of the tongue and wounds of the cheek from contraction of the masseters, luxation of the jaw, fracture of bones, abdominal hernia, and even muscular hernia of the leg. The author reports a case of the last-named lesion.

Appendicitis.—F. Terrier gives it as his opinion that there is no such thing as medical treatment of appendicitis. The diagnosis once made, prompt surgical intervention is the only logical sequel.

Anæsthesia.—Oscar Bloch urges the more frequent use of chloride of ethyl even in major operations. "Psychic pain" can be dispelled by a few preliminary whiffs of chloroform.

Revue Hebd. de Laryngologie, etc., Dec. 9 and 16, 1899.

A Case of Complete Anosmia occurred in the practice of P. Jaques in the person of a man aged forty-five years when first seen. He had not the slightest recollection whatever of ever having had an olfactory sensation. The superposition of sensorial anæsthesia and a notable diminution of tactile sensibility led Jacques to conclude that the condition was due to a previous alteration of the mucosa by a suppurative inflammation rather than to a paralysis by either destruction or compression of the olfactory nerves.

Diagnosis and Treatment of Sinus Affections.—O. Seifert has adopted for the diagnosis of this class of nasal troubles a procedure which he styles "negative politerization." After cleansing and cocainizing the nasal fossæ, he introduces into one naris a compressed air-bag and then as the patient swallows a mouthful of water he slowly allows the bag to distend. This negative suction draws the sinus contents out into the nostril. He claims that this procedure will cure even chronic cases.

Giornale Internazionale delle Scienze Med., Dec. 15, 1899.

The Prophylaxis of Tuberculosis in Children.—Olimpio Cozzolino says that it is easier to treat children than adults, because, being subject to parental guidance, they are more tractable. Infectious diseases often lead to pulmonary tuberculosis, and children predisposed to phthisis should be especially guarded from infection. Every hygienic precaution should be observed, and an open-air life insisted upon, with due regard to cold, rain, and wind. A carefully graded course of cold bathing is excellent. Antisepsis of the air passages and care of the teeth are of especial importance. Milk, fats, honey, cocoa, are valuable foods.

The Curve of Fatigue with the Natural Rhythm.—Luigi Simonelli gives the graphic results of studies upon healthy individuals, whose muscles were contracted rapidly and without artificial periods of rest between the contractions.

International Medical Magazine, January, 1900.

On the Treatment of Acute and Curable Forms of Melancholia.—Warren L. Babcock classifies, for the purposes of treatment, curable forms of melancholia as acute, agitated, and stuporous cases. In acute cases, the first indication is to combat sleeplessness. The second is to keep the patient well nourished. When auto-intoxication is present, the use of saline laxatives, mineral water, and intestinal antiseptics is indicated. Suicidal tendencies should be carefully guarded against. In agitated melancholia, forced feeding and hypnotics are generally necessary. In stuporous cases, Weir Mitchell's rest cure has met with excellent results, as has also the administration of thyroid extract.

Nervous Manifestations in the Diseases of Children.—John Madison Taylor declares that two influences stand prominent in forming the lessened resistance in infancy and childhood—cellular instability and the incomplete development of the nervous system. Hereditary transmutations, inheritance peculiarities, and the degenerative neuroses should be considered. The subject of nutrition neuroses would have here a practical bearing. Fatigue states merging into exhaustion neuroses deserve attention. The child should be observed while entirely naked. Spasmodic states are often of the gravest significance. The existence of paralyses is frequently difficult to determine in early life. The pupils and fundus of the eye should be studied. Disturbances of speech should be noted. The knee-jerk is a variable phenomenon in children.

What Are the Doctor's Duties to Pregnant Women Before Labor?—Edward A. Ayers gives the cardinal rules of gestation as follows: frequent but never prolonged out-door exercise, alternating with brief rests recumbent, with low-heeled shoes and shoulder-strap support to the skirts, the corsets being laid aside; a sensible diet that avoids an excess of meat; regulation of the bowels. Careful pelvic and abdominal examinations should be made. At least one vaginal examination should be made a few weeks before labor time. The urine should be carefully watched. The nipples should be examined a month before labor; milk scabs, abrasions, and fissures should be treated, and depressed nipples elongated by traction daily.

Nervous Dyspepsia (Gastric Neurasthenia).—Boardman Reed thinks that in more than half of the cases of so-called nervous dyspepsia the trouble is dependent upon actual disease somewhere in the gastro-intestinal tract, and he prefers to limit the term strictly to forms of indigestion or gastric symptoms which cannot be traced to any organic lesion, and are not the manifest results of even any well-known functional affection.

Some Ocular Inflammations of the Newly Born and their Treatment.—Frederick Krauss states that the two diseases which are most frequent in the new-born are a simple catarrh of the conjunctiva, and ophthalmia neonatorum or purulent conjunctivitis.

Clinical Report of a Case of Myxœdema.—Henry Beates, Jr., reports a case of myxœdema in a child brought to him at the age of two years, which has apparently been cured by the administration of the exsiccated thyroid gland.

The Medical Chronicle, January, 1900.

Typhoid Affections of the Larynx.—R. W. Marsden reports four cases, three of which required tracheotomy. In one case the laryngeal affection came on at the end of the seventh week, and the inflammatory process left such thickening that the patient has to wear a permanent tracheotomy tube. In the second case the inflammation began at the end of the fourth week; in the third there were hoarseness and laryngeal obstruction in the fourth week. The fourth case was really one of superimposed diphtheritic inflammation, to which typhoid patients are specially predisposed.

The Treatment of Nephrolithiasis with Glycerin.—A. Hermann has given this remedy in one hundred and fifteen cases. In sixty per cent. it was efficacious either by removing concretions or by removing the pains accompanying the disease. He gives the glycerin in accordance with the weight and age of the patient, keeping within the limit of from one to four ounces (by weight.) The remedy was dissolved in an equal amount of water and always taken at one dose between two meals, and repeated two or three times in an interval of several days. Larger doses sometimes caused headache in nervous people or diarrhœa in dyspeptics.

Administrations of a Mixture of Ether and Chloroform in Gynæcological Operations.—F. McFarlane Fellows considers that a mixture of two parts pure ether to one of freshly prepared chloroform possesses the advantages of safety and convenience.

A Case where Torsion of the Pedicle of an Ovarian Cyst Gave Rise to Attacks Simulating those of Recurrent Appendicitis.—F. A. Southam reports such a case.

The Present Aspect of the Antitoxin Treatment of Diphtheria.—F. Villy reviews the statistics of the subject, which are all in favor of the remedy.

Journ. of Laryngology, December, 1899, and Jan., 1900.

A Case of Nasal Hydrorrhœa.—U. Melzi reports a case of this kind occurring in a woman aged forty years and having lasted six years. Chemical analysis of the fluid seemed to exclude the possibility of a cerebrospinal source. It seemed more nearly to approach the lacrymal fluid, but no affection of the lacrymal apparatus could be found. Sense of smell was apparently unchanged. Translumination of sinuses gave negative results. All therapeutic measures, including vibratory massage, atropine, and protargol, were without effect.

The Contagiousness of Acute Suppurative Inflammation of the Middle Ear.—M. Lermoyez, while not asserting that all suppurations of the middle ear are contagious, firmly believes that such inflammation often has no other cause. A series of cases is narrated in which the element of direct contagion seems to have been present. He therefore lays down the rule that we should isolate patients, especially children, with acute median otitis.

A Case of Retropharyngeal Abscess of Auricular Origin.—Dr. Urbano Melzi has been able to find recorded only twenty-two cases of retropharyngeal abscess due to chronic suppuration of the middle ear. He adds a third case occurring in a child aged two years. Pus from the ear and the abscess contained the same bacteria.

Bulletin of the Johns Hopkins Hospital, December, 1899.

The Recognition of the Poisonous Serpents of North America.—Howard A. Kelly states that the poisonous species of snakes are few in number. Those indigenous to this country, with the exception of the little harlequin snake (Elaps) of Florida and the South, belong to the "pit viper" group, *i.e.*, they have a conspicuous blind depression over the upper lip between the eye and the nostril in the loral region. Another differential point is the triangular head with massive maxillary development. They have fewer large scales on the head and a greatly increased number of small scales giving the head a warty appearance. The snake is thicker in proportion to its length and has a shorter tail. The dorsal surface is rough. The pupil is elliptical. There are two sets of teeth, upper and lower. Just outside of the upper teeth, under the lip, are two long mucous folds hanging over the principal fangs, while a number of smaller reserve fangs are found behind. Kelly describes the copperhead, the water moccasin, and the rattlesnake, and then speaks of the harmless snakes, the Colubers.

On the Chemistry, Toxicology, and Therapy of Snake Poisoning.—Thomas R. Brown declares that the whole question of the exact position of the various constituents of venom in the proteid family must be left *in statu quo* until a more definite and scientific means of differentiation of the various members is possible. In treating snake bite, a tight ligature should be applied above the wound if it is on an extremity. The poison should be removed by scarification, cauterization, excision, cupping, or sucking. About the wound should be injected some substance destructive to the venom. The internal remedies most used have been alcohol, ammonia, and strychnine. Brown then speaks of experiments with antivenomous serum, reports of which make it probable that a real antidote to snake poison has at last been found.

The Mensuration and Capacity of the Female Bladder.—Guy L. Hunner and Irving P. Lyon review their experiments on this subject. All measurements were made on living women, generally with healthy bladders. The women were all in the knee-breast posture, with the rectum, vagina, and bladder all (with few exceptions), dilated with air. The following results were obtained:

Atmospheric capacity: With anæsthesia, 306.7 c.c. (average 17 cases); without anæsthesia, 295 c.c. (average 8 cases); total, 303 c.c. (average 25 cases). Fluid capacity: With anæsthesia, 449.6 cc. (average 15 cases); without anæsthesia, 387.1 c.c. (average 7 cases); total, 429.7 c.c. (average 22 cases).

The average measurements obtained for the four following points were: To vertex, 7.14 cm.; posterior wall, 5.77 cm.; left lateral wall, 6.70 cm.; right lateral wall, 5.92 cm.

Treatment, January 11, 1900.

Acute Rheumatism.—H. W. Syers writes of the connection between rheumatism, pneumonia, and pleurisy. It would seem that subjects showing rheumatic tendencies but not necessarily sufferers from acute rheumatism may, after sufficient exposure, manifest symptoms of ordinary pneumonia and pleurisy, and these maladies may run their course with but little indication of the rheumatic tendency which has certainly had much to do with their causation. Often there is no rheumatic history, no heart affection, and the rheumatic alliance is shown only by the presence of profuse acid sweating, by pain and swelling of joints, or by both these signs in association.

On the Biliousness Sometimes Induced by Sea Air.—F. Parkes Weber says that gouty patients, fat and plethoric persons, and those who have recently led very sedentary lives, in fact those in whom the special metabolic functions of the liver and the functions of the excretory viscera are carried out only sufficiently to satisfy the ordinary demands made upon them, are specially liable to be affected with biliousness at the seaside. Tissue catabolism is more rapid than in inland towns, and this throws extra work on the excretory organs. When these are relatively inactive, biliousness ensues.

The Treatment of Leprosy by Injection of Calmette's Serum Antivenomieux.—R. S. Woodson reports a case in which improvement was wonderful, with a prospect of future recovery.

Revue de Médecine, January 10, 1900.

Intermittent Hysterical Ptosis.—Jean Abadie reports two cases of neuropathic patients, who as a result of emotional shock were affected by visual disorder, characterized by attacks of bilateral occlusion of the eyelids. The attacks were usually of short duration and induced by some psychical disturbance. Bilateral compression of the pre-auricular region, whenever applied, was able to overcome the trouble in one case, and gave partial success in the other. During the attacks there was no physical or mental disturbance, absolutely the only phenomena present being inertia and complete flaccidity of the upper lids.

Direct Communication between the Portal Veins and the Supra-Hepatic Veins in the Human Liver.—Charles Sabourin, judging from this anatomical condition found in the course of many researches, thinks it possible that there may be two portal circulations, one for the state of rest in especial, and the other for the period of activity. This he thinks would account for the rapidity of elimination by the kidneys of liquids taken between meals, and for the prompt and energetic action of the medicines, poisons, or alcohol taken at that time, and for the remarkable rapidity with which the supra-hepatic veins become filled with coloring-matter when this is injected through the portal vein.

Tolerance of the Bromides in Epileptics of Advanced Age.—Ch. Féré reports a number of cases to show that the bromides are sometimes very well borne by epileptics over sixty years of age. He says that renal insufficiency offers a contraindication to the use of this remedy, but this condition is not peculiar to advanced age. In many cases of seeming intolerance success may be obtained by beginning with very moderate doses and increasing gradually.

Lesions and Rôle of the Lymph Glands in Epithelioma.—By Maurice Soupault and Marcel Labbé. A continued article.

Functions of the Thyroid Gland.—By Gabriel Gauthier. A continued article.

Finska Läkaresällskapets Handlingar, December, 1899.

Syphilis and Life Insurance.—J. V. Runeberg presents a statistical study of mortality among the policy holders of the Kaleva Life Insurance Company of Helsingfors. The total number of deaths among the insured from 1875 to 1897 was seven hundred and thirty-four, and of this number eighty-four, or 11.4 per cent., were due to affections of syphilitic origin. But the influence of syphilis is greater than these figures would indicate, the author believes, for there were many deaths from other causes which were undoubtedly hastened by the fact that syphilis had lowered the resisting-powers of the organism.

Uterine Fibroids in Members of the Same Family.—Otto Engström has observed five hundred and thirty cases of fibroid tumors of the uterus, and among them has seen the affection in two or three sisters in thirteen families. He thinks this coincidence is not an accidental one.

Fibro-Sarcoma of the Broad Ligament.—Axel R. Limnell reports two cases of fibro-sarcoma of the broad ligament occurring in women aged thirty-five and fifty-one years respectively. The patients were alive and in good health four and three years after the removal of the growths. In both cases the neighboring organs were healthy.

Vesico-Vaginal Fistula with Atresia of the Urethra.—L. Gratschoff reports a case in which a vesico-vaginal fistula was situated 3 cm. above the external orifice of the urethra, and this canal was occluded by a thick membrane. The author pierced this membrane and inserted a catheter, and then repaired the fistula. The operation was successful.

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Ninety-Fourth Annual Meeting, Held in the City Hall, Albany, January 30 and 31 and February 1, 1900.

WILLIS G. MACDONALD, M.D., OF ALBANY,
PRESIDENT.

First Day—Tuesday, January 30th.

President's Inaugural Address.—The session was opened by the delivery of the presidential inaugural address by Dr. Willis G. Macdonald, of Albany. He alluded to the present popularity of Christian Science, osteopathy, and similar sects in medicine, and expressed the belief that the cause was to be found in an inadequate legal definition of the term "practice of medicine." The efforts of the society's committee and of the New York Bar Association to improve the status of medical expert testimony had unfortunately resulted in nothing more than a better general understanding of the intricate problems involved. In the opinion of the speaker the legal profession is responsible for the present order of things. Presiding judges could readily remedy existing abuses by excluding medical advocates from the witness box. A voluntary society of men doing expert work could do much to regulate the condition. On the topic of State control of such chronic diseases as tuberculosis and syphilis, the speaker stated that the tendency at present was toward such State control and isolation in sanatoria. The plan had been put in operation in Germany and in Massachusetts, but was still in the experimental stage. This society had endeavored to secure legislation in favor of the organization of State hospitals for tuberculous persons. But, while working in this direction, one should carefully consider whether all our resources for the local control of this malady had been exhausted. What had been done to prevent the herding of people in crowded tenements, and to improve the food supply of these people? The address then dealt with the subject of the long-standing schism between the Medical Society of New York and the American Medical Association. The speaker stated that after a critical personal examination of the subject he could find no difference in the ethical behavior of the members of the two societies, and it seemed to many that honesty and good manners were not matters for legislation or codes, but rather the results of home training. The present medical law of the State of New York, possibly somewhat modified and with some additional safeguards, constituted what might be called the code of ethics of the Medical Society of the State of New York, and practically unified the profession in this State. The address concluded with a reference to the odious and mischievous antivivisection bill for the District of Columbia, and to the necessity for the medical profession going to the assistance of the medical corps of the army, and making Congress feel the need for prompt and favorable action on the reorganization and expansion of that body.

Report of the Committee on Hygiene.—The report was presented by Dr. Henry R. Hopkins, of Buffalo, and, after tracing the movement of public opinion regarding tuberculosis since the time of the announcement of Koch's discovery, the committee unreservedly recommended State care of consumptives.

Report of the Committee on Legislation.—DR. FRANK VAN FLEET presented this report. He said that two hundred and sixty-five bills of a medical nature had claimed the attention of the committee during the four months' session of the last legislature.

Committee on State Board of Medical Examiners.—Dr. M. J. Lewi, the secretary, presented this report. He stated that in the coming year four licensing examinations only would be held instead of five as heretofore. The total number of rejections in the past year had been one hundred and sixty-five, or 19.73 per cent. Before the committee of the State society seven hundred and thirty-eight candidates had appeared for examination, and of this number 18.69 per cent. had been rejected.

Committee on the United States Pharmacopœia.—Dr. Reynold W. Wilcox presented this report, which favored the establishment of a bureau of materia medica for the disinterested investigation into the character and value of new drugs, the bureau to be under the authority of the dicennial convention of 1900, subject to the provision that this bureau should report annually. The society formally indorsed this recommendation.

Appropriation for Pathological Laboratory of State Insane Asylums.—Dr. A. Jacobi, of New York, moved, and Dr. D. B. St. John Roosa heartily seconded the adoption of a resolution, instructing the committee on legislation to take immediate steps to secure from the legislature a continuance of the appropriation for the support of this laboratory. Both gentlemen, however, made clear their disapproval of the fact that this laboratory had deviated in its work from that originally intended, and did not hesitate to state that the resulting absence of immediate and practical results explained the disinclination of the State to continue its appropriation.

The resolution was adopted.

Carcinoma of the Stomach, with Report of Cases Showing Increased Hydrochloric Acid. — Dr. A. MacFarlane, of Albany, read this paper. He stated that the symptomatology of carcinoma of the stomach varied with the diffuseness of the growth, the presence of ulceration, and whether or not the growth was primary in the stomach. Special attention was directed to a series of sixteen cases in which the symptom generally thought to be most characteristic—*i.e.*, the absence of hydrochloric acid in the gastric juice—had not been present. Undoubtedly the absence of hydrochloric acid was of the highest diagnostic significance, yet many excellent observers had reported cases showing that the presence of hydrochloric acid was not inconsistent with the diagnosis of gastric cancer. In twelve of the sixteen cases reported in the paper the diagnosis had been confirmed by operation or by autopsy. In six the history had been suggestive of a preceding ulcer. Hydrochloric acid had been continuously present in thirteen of the cases, while in three it had been present for a time, and was afterward replaced by lactic acid. The latter acid had appeared late in the disease in four cases, and in one it had been associated with the presence of hydrochloric acid. All of the patients had suffered greatly from vomiting. Retention of food, emaciation, and prostration had been marked in every instance. In nine cases the gastric symptoms had been present for less than one year; in seven they had existed for a number of years. In seven cases pain had been the prominent symptom. Eleven of the patients had been men and five women. Their ages had varied from thirty to seventy-two years.

Dr. Samuel Lloyd, of New York, remarked that in several cases of carcinoma of the stomach that had come under his observation, in which the new growth had been in the posterior wall, and the gastric mucous membrane had not been involved, hydrochloric acid had been found present after each test meal.

Age, Sex, and Season as Factors in Nervous Disorders.—Dr. William C. Krauss, of Buffalo, read a paper with this title. He divided the life history of the individual into six epochs, viz.: (1) infancy, or up to the second year; (2) childhood or from the beginning of the third year to the seventh or eighth year; (3) boyhood and girlhood, from the seventh year to the fifteenth or eighteenth; (4) adolescence, from puberty to the twenty-fourth year in the male and the twentieth in the female; (5) manhood and womanhood, reaching to the fiftieth year in the man, and the forty-fifth or fiftieth in the woman; (6) old age, embracing the years of decline and senility. Each period of life had its own disturbances, dependent upon nerve-cell perturbations occurring during the evolution of the nerve centres. Many acute infectious processes seemed to have a predilection for the early years of life. During childhood the nervous system underwent a transformation. The period of adolescence was one of increased reflex irritability—a time when the passions and appetites were at their zenith. It might well be called the emotional period of life. Of course, there were diseases peculiar to no period of life, but affecting all alike.

Strabismus.—Dr. D. B. St. John Roosa, of New York, read a brief summary of his paper on this subject. He stated that at the time of presenting his communication on this subject last year he had done only six operations by Panas' method, but now he had performed it twenty-four times, and his colleagues in the hospital had done it twenty-two times. This gave a total of forty-six operations, but of this number only two still required further operation. This operation made it possible, in almost every instance, to cure completely strabismus at one operation. The operation consisted essentially in stretching the muscles to be divided, before dividing them. The other important features consisted in doing the operation at one sitting, and in insisting that the operation should not be done on ambulant cases, but only at the hospital or at the patient's home. He now felt that he could confidently recommend this operation of Panas in both convergent and divergent squint with the assurance that in ninety-five per cent. of the cases the correction of the strabismus could be secured at one operation.

Non-Operative Treatment of Strabismus; its Possibilities.—Dr. A. Edward Davis read this paper. The author's principal points were: (1) Hypermetropia and hypermetropic astigmatism were the causes of convergent strabismus in the majority of cases; (2) as contributory causes might be mentioned, (*a*) difference in acuteness of vision, either congenital or acquired, but usually the latter, and due to an unequal state of refraction in the two eyes, and (*b*) anything that interfered with the acuteness of vision, such as opacities on the cornea and in the vitreous or lens; (3) faulty structure, insertion, or innervation of the extrinsic muscles of the eye may cause convergent strabismus; (4) the amblyopia present in most cases of convergent strabismus he believed to be functional and acquired, and not congenital except rarely; (5) the non-operative treatment of strabismus (the use of atropine, the exclusion pad, and, in patients old enough, glasses and the use of the stereoscope) should be begun as soon as the squint is observed. Just as soon as the non-operative treatment ceased to improve the condition of the squint, it was time to operate. Delay in operating after this time was not only useless but harmful, because the habit of suppressing the image in the squinting eye became fixed, and the amblyopia was made worse. After the eyes had been operated on, the use of the stereoscope, bar reading, the pad and glasses were of the utmost value in completing the treatment by maintaining parallelism and establishing single binocular vision. The rational treatment of strabismus meant its early treatment.

The Differentiation and Treatment of Ocular Affections Commonly Met with in Family Practice.—Dr. Frank Van Fleet, of New York, read a paper with this title. He divided cases of conjunctivitis into four classes, viz.: (1) Simple; (2) gonorrhœal; (3) trachomatous; (4) traumatic. All of these varieties were purulent and contagious unless it might be the traumatic form, in which the conjunctivitis was mild, and in which only a soothing eye lotion would be required; in the more severe ones a solution of nitrate of silver would be needed, and possibly also the application of iced cloths. Nitrate-of-silver solution was best applied on a cotton-wrapped applicator, and, if the conjunctivitis was mild, it was better not to exceed a strength of five grains to the ounce. In gonorrhœal conjunctivitis Dr. Van Fleet said he made use of a solution of the strength of twenty to forty grains to the ounce, applied as early as possible and followed by the use of iced cloths. In trachomatous and follicular conjunctivitis expression shortened the duration of the disease. After the acute stage sulphate of copper should be applied. Nitrate of silver, alum, and sulphate of copper all gave good results, but should not be used continuously for too long a time, as they then aggravated the trouble. In chronic cases he recommended the alternate use of alum and sulphate of copper. As to the diagnosis, the speaker said that conjunctivitis was most likely to be confounded with keratitis, iritis, scleritis, and glaucoma. In conjunctivitis the discharge of pus was characteristic, and, as distinguished from keratitis, there were, in addition, swelling and redness. In keratitis there was a loss of brilliancy of the cornea which was not observed in conjunctivitis, and in the majority of cases of keratitis there was an opacity of the cornea. In differentiating from glaucoma the size of the pupil was an important guide; in keratitis the pupil was contracted, while in glaucoma it was dilated. In keratitis the irritation temporarily disappeared under cocaine, whereas in iritis cocaine had little or no effect. The pain was generally more pronounced in iritis and glaucoma than in keratitis. The increased tension of the eyeball in glaucoma was also a characteristic sign. In conjunctivitis ice applications gave relief, in keratitis and iritis hot applications were generally more grateful to the patient. Episcleritis and scleritis were often met with in private practice as accompaniments of rheumatism and gout, and they were best treated by the use of atropine and hot water locally, and by the internal administration of salicylate of sodium, cathartics, and alkaline waters.

Teaching of Therapeutics to Undergraduates.—DR. ELI H. LONG, of Buffalo, presented a brief abstract of his communication on this subject. He advocated teaching therapeutics by beginning with a description of the physiological action of drugs, and adopting what is knowns as "the conference method" of teaching. It was possible to do this in a most interesting way.

Teaching of Therapeutics to Post-Graduates.—DR. REYNOLD W. WILCOX, of New York, read this paper. He expressed the belief that post-graduate instruction, to be effective, must be intensely practical.

The Significance of Earache in Children.—DR. T. H. HALSTED, of Syracuse, presented this communication. He said that there were two principal varieties of earache in children, viz., (1) the neuralgic; (2) the pain accompanying inflammation. The former was usually caused by disease external to, and perhaps quite remote from, the ear. If with the acute pain in the ear there were no tinnitus, no deafness, and no redness or swelling of the drum, it was probable that the pain was neuralgic. Earache in children was usually caused by inflammation of the middle ear. When an infant was in pain, without evident cause, the physician should at once think of otitis media. Purulent otitis media was nearly always present in acute infectious diseases of the gastro-intestinal and respiratory tracts of young children, especially in gastro-enteritis and broncho-pneumonia. In many of the acute infectious diseases and in gastro-enteric disorders death was the result of an unrecognized abscess of the middle ear. When children had recurrent attacks of deafness, it was almost certain that the cause was the presence of adenoids in the pharynx.

DR. WENDELL C. PHILLIPS, of New York, emphasized the importance of keeping the nasal passages clean in the acute infectious diseases. If properly treated acute suppuration of the middle ear should never become chronic. Pharyngeal adenoids were certainly responsible for many cases of chronic suppuration of the middle ear.

DR. A. JACOBI, of New York, said that as prevention was better than cure, he favored the daily washing out of the nasal passages in all children. It should not be done with a syringe, but by the use of the nasal cup.

DR. WILLIAM S. ELY, of Rochester, said that when an infant was suffering from pain of obscure origin, the mother should be directed to place her little finger first in one ear of the baby and then in the other. If either ear was painful and tender, it would be shown by the child shrinking when the finger was inserted into the affected ear. If the physician personally made this test he might be led astray by the child shrinking from fear rather than because of pain.

Weil's Disease, with a Pathological Study.—DR. HARLOW BROOKS, of New York, presented a paper with this title. He stated that acute infectious icterus, or Weil's disease, was characterlzed by a sudden onset, the prodromata being those usually observed in typhoid fever. Within eight or ten days the temperature usually fell by lysis, but relapses were common. The disease was often epidemic, though it did not seem to be contagious. It generally attacked young adults, most frequently healthy males. Nearly all the reported cases had been those of Germans, French, and Russians. He had been able to find only three cases reported in America. The disease was undoubtedly an infection, the source being almost certainly putrid animal flesh. For this reason butchers were specially subject to this disease, as were also those persons subsisting largely on sausage and other uncooked meats. This probably explained the comparative rarity of the disease in this country. Both clinically and pathologically there was a close resemblance between Weil's disease and acute yellow atrophy of the liver.

Treatment of Temperatures and Heart Failure.—DR. A. JACOBI, of New York, in this communication dwelt upon the possible value of Credé's colloid silver. His own experience with this method of dealing with temperature in disease was limited to a few cases of phlebitis, puerperal fever, and pyæmia.

Pathogenesis and Treatment of Acute Croupous Pneumonia in the Light of the Newer Pathology.—DR. JAMES K. CROOK, of New York, read a paper with this title. He stated that the pneumococci were not invariably present in pneumonia, nor did they invariably cause pneumonia. Fraenkel's microbe appeared to be present in all conditions, yet was not invariably present in one. On the other hand, it had been demonstrated that pulmonary hepatization might be produced by the colon bacillus, the Loeffler bacillus, and the bacilli of typhoid fever and of erysipelas. He was not disposed, therefore, to place much reliance on the pneumococcus either as the cause of acute lobar pneumonia or as a basis for treatment. It had been proved that the serum from the blood of animals suffering from pneumonia conferred temporary immunity upon animals into which it had been injected. Although various remedies had been recommended as effective in pneumonia, there was still no proof that any of these agents influenced the pneumococcus in the body in any way.

Dr. Andrew H. Smith, of New York, said that he wished he could sufficiently emphasize the importance, to a correct conception of pneumonia, of the double circulation in the lung. A fact well known to every first-year medical student had heretofore been entirely overlooked in its relation to the one disease in which it afforded the indispensable condition upon which the disease depended. Like all other organs the lung had a circulation by which its structure was nourished, and which derived its blood from the left side of the heart, but in addition it had an entirely independent circulation for functional purposes, which received its blood supply from the right side of the heart. This latter circulation was not interested in maintaining the structural integrity of the lung. This circulation might be entirely suppressed without structural damage, as when the lung was compressed by intrapleural effusion. It was his belief that the essence of a true lobar pneumonia was the infection of the air cells with the pneumococcus—the specific parasite. Other organisms might participate in the infection, but in proportion as they did so the case would not be typical. The one clinical feature that, in his opinion, always indicated the predominance of the pneumococcus as the causal factor was the defervescence by crisis. When this occurred, he believed one might always be sure that the infection was chiefly by the pneumococcus. When the defervescence was by lysis, one might suspect that other germs were taking a prominent part. It could, however, only be suspected, for lysis might occur with pneumococcic infection if the local process spread slowly, and one portion after the other of the lung kept up the supply of toxin. The pneumococcus was present in the upper air passages and, to some extent, in the large bronchial tubes of most persons in health. It did not grow rapidly in these localities, only individual bacilli being found ordinarily. It grew freely, however, on serous or synovial membranes. With the former might be classed the lining membrane of the air cells. If the pneumococcus penetrated this far, a colony was started, and the irritation so produced caused an exudation, in which the growth continued until the medium became too much contaminated to serve longer as such, and then the process was stayed. This organism was peculiarly sensitive to acid, and the pneumonic process seemed to increase the acidity of the lung. The speaker then contrasted pneumonia with diphtheritic infection, more particularly as regards the direct action of the pneumococcus and its toxin, and the fact that while in diphtheria the microbe grew in the tissue itself, in pneumonia it grew on an exudate that was poured into the air cells and was not a part of the pulmonary structure.

Dr. Henry R. Hopkins, of Buffalo, insisted most emphatically on the necessity of supplying an abundance of pure air to the pneumonia patient.

Classification of Infectious Diseases.—Dr. William H. Thomson, of New York, presented a communication on this subject, in which he dwelt upon the important, and often disastrous, results from the careless use or misuse of the terms "contagious" and "infectious." We had fortunately got rid of that nightmare "miasm," or a deadly gas. The following classification was recommended: All diseases due to the presence of their specific living micro-organisms in the body were "infectious"; hence, all infectious diseases were communicable from the sick to the well. They were divisible into three classes, *i.e.*, (1) the contagious; (2) the non-contagious; (3) the inoculable. The contagious communicable diseases were those in which simple proximity to the infected was sufficient to communicate the infection to those susceptible to it. The non-contagious communicable diseases were those in which the communication was not by simple proximity to the sick, but through intermediate means of communication. The inoculable diseases were those which gained entrance through wounds, as in hydrophobia. All infectious diseases could be prevented by measures of disinfection applicable to each. Dr. Thomson suggested that the foregoing facts be summarized and presented to the public.

Discussion on Prophylaxis in Gynæcology: the Etiology and Prevention of Uterine Disease Before Pregnancy.—Dr. W. Gill Wylie, of New York, opened this discussion, taking up the special topic indicated. He said that for a young girl to develop well into a healthy young woman she must have a surplus of strength; otherwise the generative organs were almost sure to suffer. Up to the age of about ten years girls and boys should be allowed the same freedom, and should be prevented from undue use of the brain and the excitement incident to frequent association with older ones. He believed that the large number of women of the better class, having poorly developed generative organs, owed their defective condition very largely to the pernicious custom in this country of encouraging education and precocious maturity in young girls. The disastrous effect of such unwise early training on parturition and on the subsequent life of these individuals was clearly pointed out. Next in importance was the avoidance of habitual constipation. The deleterious influence of the customary dress of women and the tendency to a sedentary life also received attention. He advised rest during the menstrual period only when pain and other symptoms indicated that this function was not strictly normal. An exception was made in the case of young girls in whom this function had not been thoroughly established. Dysmenorrhœa and profuse menstruation might be successfully treated in many instances solely by removing these young girls from school, and encouraging a free out-door life and association with those younger than themselves.

Prophylaxis After Marriage.—Dr. Ralph Waldo, of New York, discussed this topic, touching more especially on the results of early venereal infection, of prevention of conception, and on the Credé method of preventing ophthalmia neonatorum. The speaker stated that most of the cases of pyosalpinx coming under his observation were the result, not of gonorrhœa, but of septic endometritis following abortion, usually intentionally induced.

Dr. M. D. Mann, of Buffalo, said that in the first year of menstrual life girls should be kept away from school and quietly at home during the menstrual period. Some mothers applied a small corset to their girls when they were yet very young, and made them wear the same size for a number of years. In this way all of the evils of tight lacing were produced almost unconsciously to the wearer of the corset. All abortions should receive careful treatment, for nature had never intended that they should occur and had consequently made poor provision for them.

State Care of Tuberculous Patients.—The evening session was held in the assembly chamber of the State capitol, and members of the legislature and the general public were invited to be present. The topic for discussion was "The State Care of Tuberculous Patients."

The Attitude of the State and Municipality in the Care of Pulmonary Tuberculosis among the Poor.—Dr. Edward O. Otis, of Boston, Mass., opened the discussion with a paper on this subject. He said that pulmonary tuberculosis was the cause of about one-seventh of all deaths. It went almost everywhere that man went, and was worse where human beings were crowded together. Three-fourths of its victims were stricken at the most valuable period of life. The disease was curable in its early stages, but such treatment was expensive and beyond the means of the poor. The latter were a constant menace to those immediately about them, and also to the public, through their ignorance and carelessness regarding the proper care of their sputa. On the ground of economy, prophylaxis, humanity, treatment and care should be given the poor consumptive. The city and State had already assumed that it was their duty to provide treatment and care for the unfortunate poor suffering from other diseases and defects. For the defective class the State had established insane asylums and institutions for dipsomaniacs and for the feeble-minded. There was, however, an enormous mass of consumptives for which no provision had been made. The curable cases lost their chance for cure, and the more advanced ones must go to the poorhouse. The interval of time between the inception of the disease and the manifestation of symptoms was so long that the cause was often forgotten. Only recently had it been shown that the old theory of hereditary transmission was inadequate. When the public once awakened to a realization of these facts, it would rise and demand State and municipal care. To this end he suggested that the crusade against tuberculosis should be made a popular one; if need be, a fashionable one. In England the daily press had been a powerful factor in moulding public opinion. In the speaker's opinion, two sets of institutions would be required, viz., (1) hospitals for consumptives in or near the city, for the reception of poor consumptives in all stages of the disease, erected and maintained by the municipality; (2) several State sanatoria favorably situated climatically and not too far from the city, which would furnish the majority of its clientèle. These sanatoria should receive only the incipient cases. Undoubtedly other hospitals for consumptives would be erected and supported by private charity, but the initiative must come from the State. A portion of the expense could be collected in some cases from the patient or his friends, or from the city or town from which he came. Of course the entire maintenance could be provided for by a per-capita tax. As a matter of fact, the State and the municipality must ultimately provide for the poor consumptive if the early and more effective provision recommended should be withheld. By reducing the number of consumptives by this enlightened method there would result a yearly saving of lives, having a distinct money value to the community. Knowledge ever brought responsibility, and in this instance certainly we should not shrink from it. The probable expense per capita would be $300 or $450 annually. Undoubtedly favorable sites would be found in the central and western parts of the State. The great desideratum was pure air. Proper treatment could not often be obtained at home. The modern treatment of consumption was an exacting, long, and expensive one, and was entirely beyond the grasp of the poor. Hardly a single European country at the present time was without one or more sanatoria for consumptives. England had seventeen hospitals, homes, and sanatoria of this kind, and it was probable that before long such sanatoria would be scattered thickly all over Europe, just as at one time leper-houses were to be found all over that continent. The physician was the one who must properly mould public opinion on this important matter.

Remarks upon the Work Accomplished at the State Hospital for Consumptives at Rutland, Mass.—Dr. Vincent Y. Bowditch, of Boston, read this paper. The patients, he said, had been first admitted to this hospital in October, 1898, and at first the more advanced cases had not been excluded; hence, it was probable that still better results would be shown at the end of the second year. The number of patients coming upon his service there was 212. Of these, 126 had been discharged. Of this number, 35 had been "arrested"; 37 much improved; 17 moderately improved; and 24 not improved at all. One patient had died, and one had had only a bronchitis. Of the 35 "arrested" cases, 27 should be considered as incipient at the time of their admission, and 8 had presented evidences of rather advanced disease in both lungs. Founded upon this experience certain suggestions were offered. The ravenous appetites engendered by out-door life required a large supply of nourishing food, particularly an abundance of milk and eggs. The fact that in every such sanatorium amusement must be provided should be kept steadfastly in mind. It had been very properly suggested that an effort be made to give the patients light occupations consistent with their state of health. One very important result of the establishment of such sanatoria was the educational part which they played. It was, perhaps, well to caution against an excess of enthusiasm, for there was a strong temptation to exaggerate in connection with any subject which had caught the popular fancy.

Similar Results of the Climatic and Sanatorium Treatment of Tuberculosis in the Adirondacks.—Dr. Edwin R. Baldwin, of Saranac Lake, read this paper. Great efforts had been made to trace the patients, he said, who had been discharged in fifteen years. During this period 1,200 patients had been cared for, exactly three-fourths of whom were recorded as being "advanced." This left only one-fourth really "incipient." During the last two years, however, one-third of the new cases had been incipient. Of the whole number, 277, or twenty-three per cent., had been discharged apparently cured; 669, or fifty-six per cent., with the disease arrested; 230, or nineteen per cent., were in a stationary or improved condition; 24, or two per cent., had died at the institution. By "apparent cure" was meant cases in which the rational signs of phthisis and the bacilli in the expectoration had been absent for at least three months, or who had no expectoration at all, any abnormal physical signs being interpreted as indicative of a healed lesion. "Arrested cases" were those in which cough, expectoration, and bacilli were still present, but in whom active signs had been absent for about three months. One-fourth of the whole number, or four hundred cases, were perfectly well, or believed to be. Of the incipient class, sixty-eight per cent. had been discharged apparently cured, while only eleven per cent. of the advanced ones had recovered. It should also be noted that only two hundred are known or believed to be living, who still had cough or expectoration, who were otherwise well. All of the remainder were known to be or believed to be dead. Present experience showed that only one out of fifteen applicants to the institution was in the incipient stage, or was favorable for recovery. But these figures did not take cognizance of the large number of persons who had been saved from infection with tuberculosis. Out of two hundred and forty-eight perfect recoveries recorded up to 1898, two hundred and fifteen, or twenty-two per cent., of all those discharged up to that time were known to be, or believed to be, perfectly well at present. A period of two years had been, in their experience, a fair test of permanency, but it had been clearly shown to be dependent upon the habits, occupation, intelligence, and vicissitudes of life of the individual rather than an inherent tendency of the disease to relapse after having been healed for so long a time. Indeed, the results would be better if the patients could remain longer in the institution. The patients were drawn from a fairly intelligent class of people The cost to the patient per week was only $5. The administration expenses had been so slight that the cost of maintenance had been only $7 per week. Dr. Trudeau received no salary for his services.

Infectious Character of Tuberculosis, and the Prognosis of Incipient Pulmonary Consumption.—Dr. George Blumer, of Albany, read this paper. He stated that the disease now known as tuberculosis had existed as a separate clinical entity for a comparatively short time. It was not until after the middle of the nineteenth century that its infectious character had been clearly recognized. In 1865 had come the first announcement of the infectious nature of the disease, as proved by inoculation experiments on animals. In 1882 Koch had published his celebrated observations on the tubercle bacillus, in which he showed that this organism was always associated with tuberculosis, that it could be cultivated outside of the body, and that even after many generations of cultivation the bacilli were capable of reproducing the disease when inoculated into susceptible animals. The claim that the mortality from tuberculosis in the first year of life was twenty-three per ten thousand gave some color to the theory that at times the disease might have a prenatal origin. Experiments had shown that when the sputum was received into spit-cups and the room was absolutely clean, the air of the room was free from tubercle bacilli. Strauss had found tubercle bacilli in the nasal passages of nine out of twenty-nine healthy physicians and nurses in hospital. In confirmation of the belief in air infection were the relatively numerous cases in which previously healthy individuals had developed pulmonary tuberculosis after living in rooms formerly occupied by tuberculous individuals. The researches of Flick regarding infected houses were interesting as showing that only ten per cent. of the tuberculous houses in Philadelphia were isolated houses. It was also shown that the distribution of tuberculosis corresponded almost exactly to that of the other more acute infectious diseases. Other confirmatory evidence of air transmission was to be found in the sudden outbreak of many cases of tuberculosis in small towns following the introduction of one or two cases into the community. Experiment had shown that individuals in coughing and speaking threw off spray containing tubercle bacilli. The rarity of primary intestinal tuberculosis in adults was shown by the fact that in one thousand autopsies at Munich there had been but one of primary intestinal tuberculosis. Northrup, in one hundred and twenty-five post-mortem examinations on children, found only three of tuberculosis of the mesenteric glands alone. Cheese, whey, and particularly butter, had been found to contain tubercle bacilli in many instances. In Berlin, Robinowitch found fourteen per cent. of the butter examined to be infected with the tubercle bacilli. The weight of evidence was against the flesh of animals being a source of infection, largely, no doubt, because it was usually cooked before being eaten. Various methods of skin infection had been reported. Primary infection through the genito-urinary tract was probably exceedingly rare; both in men and women the deeper rather than the superficial portions were the first attacked. As to prognosis, the speaker said that no other chronic disease showed a greater tendency to heal. Clinically there was good evidence that, taken in its incipiency, pulmonary tuberculosis was very amenable to treatment. The report of the Loomis Sanatorium for 1898 showed about fourteen per cent. of cures, and the cures at the Falkenstein Sanatorium in Germany are said to be about fifteen per cent.

Legislation concerning Tuberculosis; Past, Present, and Future.—Senator Horace White, of Syracuse, spoke on this topic, reviewing the evidence that had been presented by the medical profession, and predicting enthusiastically and positively that the desired establishment of sanatoria could not fail of speedy accomplishment as soon as the public had grasped the problem, and appreciated the vital interests at stake.

The Policy of the State Relative to the Spread of Tuberculosis.—Dr. Enoch V. Stoddard, of Rochester, read this paper. He said that the sanitary welfare of the community had been for a long period a source of solicitous attention, and there had thus grown up a department of public health. One of the common causes of pauperism was the prevalence of disease. It was well known that the annual death rate from pulmonary tuberculosis in this State was about fourteen thousand, and that the incipient and advanced cases made a total of nearly sixty thousand. Comparatively few recalled the fact that the State was contributing in a greater or less extent to the maintenance of one in every two hundred and fifty-one of its population. It would seem, therefore, that the province of the State was not so much to assume the direct and total care of such patients as to establish such a system, by well-advised legislation, as would enable the several communities of the State to bear their part in this care. The great desideratum was to educate the patients and the public in general in the means of prevention as well as of cure. The province of the State should be, therefore, mainly educational, and only custodial so far as might be necessary to insure those object lessons in care that might be required by a few communities. It was well known that consumptives were exceedingly averse to being removed to any great distance from their homes, and hence the importance of what might be termed "home sanatoria." The State of New York presented suitable sites for such sanatoria within easy distance of almost every large centre of population within its borders. It had been found that the cure of pulmonary tuberculosis in a home sanatorium was less likely to be followed by relapse than in the more distant sanatoria. Moreover, such home sanatoria possessed a great educational value. The chronic cases should be cared for by the municipalities in which such cases occurred. The State already possessed a well-organized system of protecting the public health. The enactment of a law along the lines just indicated would lead to the establishment of a system of local sanatoria for both incipient and advanced cases.

Taxation with Relation to State Care of Consumptives.—Hon. Otto Kelsey, of Geneseo, spoke on this topic. He pointed out the enormous expense now borne by the State, and, as a member of the legislature, expressed his belief that it was unwise at the present time to make the large appropriation asked for. It was not only the sum asked for now, but the indefinite and probably very large appropriations that would be demanded for this work in the future.

Dr. John H. Pryor, of Buffalo, made a most vigorous and telling speech in advocacy of State care of consumptives. He showed the fallacy involved in the oft-repeated assertion that consumption was decreasing among us. Michigan had seen fit, six years ago, to adopt a plan of State care, and already it was evident that tuberculosis was decreasing in that State more rapidly than elsewhere. What was asked for was that the consumptives be taken care of at the right place and the right time until they were well, and not to take care of them at the wrong place and at the wrong time until they were dead. We had just been told that the State could not afford to make the appropriation asked for because of the large sum needed for the canal system, but it seemed to him that the saving of human life was more important than the canals.

Dr. Daniel Lewis, of New York, argued that the movement under discussion should be begun by providing for the advanced cases, as they were a great menace to public health.

Dr. Arthur G. Root, of Albany, spoke of the educational value of consumptive sanatoria, and the economic aspects as shown by the desire of organized charity to co-operate with the medical profession in this movement.

Dr. Samuel B. Ward, of Albany, pointed out that the legislature had not been asked to take care of the sixty thousand consumptives in the State, but only to make provision, as an object-lesson, for a few of these persons.

Dr. George R. Fowler, of New York, commented upon the encouraging change of opinion on this subject that had recently taken place in the medical profession.

Dr. Henry R. Hopkins, of Buffalo, urged immediate action on the ground that delay meant to thousands a cruel and unnecessary fate. When thousands were marching to the grave, and it was in our power to save them, how could an enlightened and humane profession withhold this succor?

Dr. Brush, of Brooklyn, discussed further the economic side of the problem, and pointed out the small beginning made last winter in the passage of the Henry law.

Dr. Nelson H. Henry, of New York, a member of the assembly, commented upon the general lack of information and wide differences of opinion among physicians on this subject. He advised being contented with a small appropriation, if more could not be obtained.

Dr. Z. Taylor Emory, of Brooklyn, deprecated the lack of enthusiasm and co-operation evinced by the medical members of the legislature.

Second Day—Wednesday, January 31st.

The greater part of the morning was given up to a personal inspection of the new Albany Hospital, and to an interesting clinic at that institution.

Human and Bovine Anthrax.—Dr. Frank W. Ross, of Elmira, in this paper detailed an interesting experience with this disease. Regarding the diagnosis, he said that the typical lesion could hardly be mistaken for anything else, although it was true that there was a somewhat striking resemblance to vaccination. Cattle dying in virulent epidemics sometimes showed no gross lesions at first. The advantages claimed from vaccination for this disease by the Pasteur method were certainly noteworthy. In the preparation of the serum the absolute destruction of the anthrax spores must be assured by experiment. The wonderful results secured from this serum certainly justified its use in man. Dogs, pigs, and rats were practically immune. Excision, curetting, and cauterization of the pustules were justifiable in any stage. The virulent systemic poisoning should be overcome by symptomatic treatment.

Bovine Tuberculosis.—Dr. James Law, of Ithaca, discussed this topic. He stated that experience with the tuberculin test showed that in most herds tuberculous generalization was not observed. The average bacillus of bovine origin habitually failed to produce a rapid extension and generalization of the disease. The tubercle bacilli of cattle were thicker and shorter than tubercle bacilli in man, but they often presented almost exactly the same morphological characteristics. Our neighboring States demanded that the tuberculin test be applied to cattle, and, as a result, the tuberculous animals, as determined by this test, were sorted out and sent into New York State, there being at present no law preventing ths.

The Preparation of Tuberculin; its Value as a Diagnostic Agent, and Remarks on the Human and Bovine Tubercle Bacilli.—Dr. V. A. Moore, of Ithaca, presented a résumé of his paper on this subject. He said that properly prepared tuberculin could not possibly contain living tubercle bacilli, because it was twice raised to a temperature which killed these germs. It was usually prepared from sputum bacilli. The tuberculin reaction consisted simply in a temporary rise of temperature on the part of the tuberculous animal; it produced absolutely no effect on the healthy animal, as shown by the thousands of tests already made. This presupposed that one was familiar with the normal variations of temperatures. This was especially important in cattle, because in them there was often a normal variation of three or more degrees. Excitement, food, variations in surroundings, and the application of cold water all produced marked changes in temperature which might last for three or four hours.

Dr. James K. Crook, of New York, spoke of his experience with the tuberculin in several cases of suspected tuberculosis, and expressed the opinion that it afforded but little aid to diagnosis in the human subject.

Dr. F. W. Ross, of Elmira, said that seventy-two cattle affected with tuberculosis all gave the tuberculin reaction, and in seventy of these the gross lesions were apparent at post-mortem examination. The old cattle were infected through the lungs, and the young cattle through the intestinal tract, showing that the latter had become infected secondarily from the sputum.

The Medical Examiner for Life Insurance and His Responsibilities.—Dr. S. Oakley Vander Poel, of New York, read a paper with this title. He said that formerly all life insurance companies were obliged to decline from twelve to fifteen per cent. of their applicants, in consequence of some impairment of family record or physical disability. Of late the most progressive American company had studied all its declined applications between the years 1875 and 1890, and had ascertained the outcome of each individual; if alive, the condition of health, and if dead, the cause of death. From the data thus obtained it had been able to differentiate and collect aggregated groups of persons suffering from the same disorder, which had supplied a basis by which to adjudicate upon a special case under consideration. Now, practically all of this fifteen per cent., who had been formerly declined, were accepted on a sub-standard basis, provided they were not acutely ill, or there was no moral hazard. This company now required its examiners to present all the facts in the case; or, in other words, to give a pen picture of the applicant, upon which the home office of the company based the insurance value of the risk. The examiners were relieved from the embarrassment of declining an individual, but their responsibility toward the company remained the same. The company was still as conservative as heretofore, as an applicant, to obtain a standard policy, must still possess the same degree of physical excellence as formerly; the standard was simply separated from the sub-standard with the same care as when insurance was denied the latter class. The medical examiner should remember the difference in the mental state of the patient and the applicant for insurance. The latter was nervous, fearing the development of some hidden ailment, and, if young, the examination might induce, as it were, a mild form of shock. The patient concealed nothing from his physician; his attitude was one of unreserved co-operation. The memory of the insurance candidate was less acute, and his state of mind was one of antagonism. The skilled examiner had learned this lesson. The company now insured under-average as well as selected lives, offering insurance to practically all who apply. In each case it adjusted the plan of insurance to the insurance value of the risk. The medical examiner's report served as a basis of valuation, and determined the plan upon which the insurance was offered.

Experience with the Angiotribe.—Dr. J. Riddle Goffe, of New York, read this paper. He used the latest and best modification of the instrument in sixteen cases, fifteen of which were hysterectomies. He had found that the use of this instrument shortened the operation, facilitated convalescence, and made the treatment more convenient.

Dr. W. S. Stone, of Washington, D. C., said that he had used the same angiotribe about twenty-five times, for the most part in abdominal hysterectomy, and in no instance had he experienced any trouble from hemorrhage. The use of the angiotribe, he believed, avoided both hemorrhage and suppuration in pelvic surgery.

The Importance of Early Recognition of Acute Inflammation of the Middle Ear by the General Practitioner.—Dr. Edward B. Dench, of New York, after calling attention to high temperature in young children, otherwise unaccounted for, as good ground for suspecting inflammation of the ear, described in detail the mode of examination. In the treatment, early and free incision of the drum was advised, and the use of such "ear drops" as oil and laudanum was characterized as worthy of being made a criminal offence.

Dr. James F. McKernon, of New York, took exception to this wholesale condemnation of "ear drops," claiming that the instillation of a warm four-per-cent. solution of cocaine in camphor water was often beneficial.

Uterine Fibroids Complicated by Pregnancy.—Dr. W. F. Ford, of Utica, presented a paper on this subject in connection with photographs and histories of several illustrative cases. The dangers from this complication were chiefly overdistention or rupture of the uterus, interference with a normal first stage of labor, and sepsis resulting from infection after delivery. When the lower third of the cervix and the entire uterus were free from neoplasm, nothing need be done. If, however, the neoplasm was large enough to block the birth canal, the obstetrician was called upon to decide between Cæsarean section and hysterectomy. If the tumor was in the anterior wall, Cæsarean section could not well be done.

Anniversary Address by the President: "The Relation of the Clinical Laboratory to Modern Surgery."—Dr. Willis G. Macdonald, of Albany, delivered this address. He recommended the practice of taking at irregular intervals, and without notice, specimens of surgical dressings, ligature and suture material, and from the skin of the patient. Each new lot of catgut or other similar material should be tested in the laboratory before being accepted and used. The speaker said that delayed shock and fat embolism had been a very acceptable refuge in many cases of overwhelming sepsis. The use of the antistreptococcus serum in cases of surgical sepsis, he declared, had proved sadly disappointing, but further study of the streptococci might quite possibly change these results. Tetanus serum certainly possessed antidotal properties. When given in suitable quantities he had seen improvement invariably follow. Modern surgery demanded that urinary examinations before operations should include an estimation of the total solids for twenty-four hours, together with examination for indol, peptone, and similar abnormal ingredients. Routine examination of the blood was also very important. The determination of the percentage of hæmoglobin often afforded the surgeon valuable information. Microscopical examination of the blood was a valuable aid in making a differential diagnosis between chills due to nervousness, to malaria, to sepsis, and to other causes

New Rectal Instruments.—Dr. Samuel G. Gant, of New York, exhibited several new rectal instruments, including a convenient rectal speculum, and a pile clamp having parallel blades, thus greatly diminishing the chance of hemorrhage.

A Unique Case in Obstetrics.—Dr. F. H. Parker, of Auburn, reported a case in which he had extracted a small macerated fœtus from a woman, and a few days later had delivered her of a fully developed and healthy child. The history of the case seemed to indicate that the dead fœtus had been carried for upward of two years. There was nothing unusual in the appearance of the secundines.

Further Investigations into the Cause of Cancer.—Dr. Roswell Parker, of Buffalo, presented a communication on this subject. He stated that the conclusions presented by him last year had been unexpectedly sustained and corroborated by other observers, both at home and abroad. The speaker reiterated his assertion that cancer was undoubtedly on the increase, and added that this could not be wholly explained by the improved methods of diagnosis. It should be remembered that just in proportion as methods of diagnosis were improved, the number of deaths would be reduced. It was probable that we must assume a certain predisposition of the tissues, either inherited or acquired, before cancer formation was possible. Cancer was virtually never seen on the back, save in points within easy reach of the hands. It appeared on the face chiefly in those who did not use soap. It did not occur, as a rule, on the lips of women because they did not smoke. Cancer of the ear usually began on the upper and outer border, *i.e.*, the least resisting part. Dr. Parker presented a list of cases collected by him, bearing upon the age at which cancer most frequently developed. In two of these cases, carcinoma of the uterus was present in infants of two years of age. In conclusion, the speaker asserted that he saw in the work of the State cancer laboratory constantly increasing evidence in support of his belief in the parasitic nature of cancer. The experience in the State laboratory showed that histology alone would not give the necessary information concerning certain bodies that had been found in the course of the study of carcinoma.

The Curability of Leprosy.—Dr. George H. Fox, of New York, presented this paper. He stated that in the large proportion of cases leprosy terminated fatally, but exceptionally all traces of the disease disappeared, and the patient probably became immune to it thereafter. A change in habitation, a cheerful prognosis, and a resort to certain drugs were characterized as important factors in securing a cure. The number of reported cures was certainly very small. When these individuals were removed from the locality in which the disease was contracted, and transferred to a region in which leprosy was not endemic, an improvement, often temporary, was very commonly noted. He had found chaulmoogra oil a valuable remedy. In some instances it caused a degree of nausea that was prohibitive; in others, large doses would be tolerated for a long time. Cases could be cited in which tubercular leprosy had subsided under treatment, and the individuals had been apparently cured completely. He attributed much of his success in this disease not only to the use of chaulmoogra oil but to the cheerful prognosis given.

Some Questions about the Care of the Hair.—Dr. George Thomas Jackson, of New York, read this paper. He said that in serious illness, especially in fevers, nothing could be done to prevent the fall of the hair, because this was the result of temporary interference with its nutrition. The physician should vigorously oppose cutting off the hair, particularly in women, as the advantages were slight and the risk of unpleasant consequences was great. The hair should be combed and brushed daily, unmindful of the amount of hair falling out, and once in a week or two the hair should be washed. The most convenient soap was the ordinary tincture of green soap. At short intervals it was well to rub into the scalp a pomade of precipitated sulphur of the strength of one drachm to the ounce. He now believed that the present custom of abandoning the use of pomades and wetting the hair was responsible for much of the prevalent baldness. If the head was rubbed night and morning, and a little pomade, not liable to become rancid, was rubbed in, he felt sure there would be less baldness. It was not wise to have the hair of a girl cut after the age of ten or twelve years, as this rendered it less silky. Of all the present customs of caring for the hair, perhaps the most ridiculous was that of hair-syringing, a procedure founded on antiquated and erroneous notions.

Some Remarks on Surgery of the Nasal Septum.—Dr. Robert C. Myles, of New York, said in this connection that Bosworth's operation was to be recommended for that very large class of cases in which large formations were present along the natural line of the bone. In properly selected cases brilliant results had followed resort to the modified Asch operation. The most marked relief had been afforded in those cases in which there had been pressure against the fossa of the superior maxillary bone.

Address: "Education and the Profession of Medicine."—A. V. V. Raymond, D.D., LL.D., president of Union University, delivered this address. He began by asking the question, "Was the great aim of education to give one an ability for a certain occupation or profession?" and answered it emphatically in the negative. The true theory of education, he declared, comprehended the development of all the powers belonging to the individual as a man; he was to be educated because he was a man, not because he was to be a merchant, or a machinist, or a lawyer. The speaker then discoursed upon the comparative value of such studies as mathematics and languages in the preparatory school. By a reorganization of our whole system of primary and secondary school instruction it was possible, he believed, to give a man a good school and collegiate training, a full course in the medical school and a service in hospital, and still allow him to enter upon the practice of medicine at about the age of twenty-five. The speaker predicted that this change was sure to come here, as it had already occurred in other countries.

Address: "Rational Therapeutics versus Christian Science and Similar Superstitions."—James M. Bulkley, D.D., LL.D., of New York, editor of the *Christian Advocate*, delivered this address. He stated that anti-medicine faith-healing was based on the proposition that disease was always the work of the devil, and that a special kind of faith was requisite, and that if that special faith was exercised the disease would disappear. The speaker declared that it was a sad fact that a large part of the medical profession firmly believed that there was no distinction between anti-medicine faith-healing and Christian Science, whereas, as a matter of fact, there was only one point of similarity, *i.e.*, they both refused to use medicine. Christian Science was more subtle. He had been familiar with the evolution of the high priestess of that so-called science. He possessed the only complete copies in existence of all that Mrs. Eddy had set forth. If the theory of the Christian Scientists was true, food would not be necessary to life, but, according to Mother Eddy, it would be foolish to stop eating until we were able to get a fuller comprehension of the living God! Mrs. Eddy claimed that she discovered the great truths of Christian Science by experiments made by her while she was practising homœopathy. The discovery of the effect of the mind over disease had been impressed upon her by the results obtained with medicine "attenuated until not a trace of the original remedy was left." In conclusion the speaker declared that Christian Science, as a system of therapeutics, would have died ere this if it had not been put forward as a religion; and it would have died as a religion if it had not been put forward as a system of therapeutics. He predicted that the forces which had raised this intellectual balloon would in time be the means of its final destruction.

A Contribution to the Surgery of the Stomach.—Dr. H. Beeckman Delatour, of Brooklyn, presented in this report the histories of several illustrative cases, and particularly reports of a case of gastrotomy, and one of gastrectomy for adeno-carcinoma. In the latter case, after recovery from operation, the woman became pregnant, and at full term was delivered of a healthy child. After delivery there had been uncontrollable nausea and vomiting, and an exploratory incision had revealed a recurrence—then twenty months after the gastrectomy. He raised the question as to whether this recurrence might have been prevented by terminating pregnancy some months earlier.

The Management of Puerperal Infection.—Dr. L. W. Seers, of Syracuse, presented this communication. He stated that Dr. Bacon, of Chicago, had shown that seventy per cent. of all the deaths from childbirth were due to sepsis, and that two hundred persons die annually in that city from that cause. He advised against delaying treatment for the results of a bacteriological examination, and against the use of the curette until it was evident that intra-uterine irrigations were impotent to control the affection. Curettage should then be done cautiously, and the cavity of the uterus be packed lightly with gauze. True septic infection he considered a contraindication to the use of the curette.

(To be concluded.)

THE PRACTITIONERS' SOCIETY.

One Hundred and Fifty-first Regular Meeting, Held on Friday, December 8, 1899.

A. Alexander Smith, M.D., President, in the Chair.

A Case of Acromegaly.—Dr. F. P. Kinnicutt reported in brief a case of acromegaly. The patient, a man, twenty-nine years old, was admitted to the Presbyterian Hospital in November, 1899. His family history was negative, his personal history unimportant previous to the onset of his present illness, six years ago. At about this date he began to suffer from headache of an intermittent character confined to the left supraorbital region and the left side of the head. The headache, which was very severe, continued to be intermittent in character until two years ago. Since this date it had been almost continuous during his waking hours, and had often prevented sleep. Three years ago his friends first noticed that his face was growing larger, and this enlargement had gradually increased up to the present time. The hands and feet had also gradually increased in size, the lips and tongue had become thicker, and the nose more prominent. Three years ago he wore a six and seven-eighths hat; the size he now required was seven and a half. Aside from his headache he had suffered from few if any subjective symptoms. On admission to hospital the patient presented a characteristic appearance.

The following notes were made by Dr. Kinnicutt: The face was without expression. The head was enlarged as a whole, the increased size being especially marked in the face. The malar prominences were much exaggerated. Both maxillæ were greatly enlarged, the inferior to a greater degree than the superior. The enlargement was next marked at the symphysis. There was only slight prognathism. The lips were thick; the mucous membrane was everted, that of the lower lip especially so. The tongue was greatly increased in volume. The alveolar processes were hypertrophied; the teeth of the lower jaw were separated. The nose was greatly enlarged, particularly toward its tip; the alæ were much thickened, and the anterior nasal passages dilated. The frontal eminences were enormously exaggerated and the orbital ridges enlarged. The forehead above the frontal eminences was retreating. The ears appeared to be normal in size. The hands were massive, the increase in size being in their width and thickness. The fingers apparently were not increased in length, but greatly in width and thickness. The enlargement appeared to be chiefly in the soft structures. The skin was moist. The distal ends of the radius and ulna were enlarged; the muscles of the arm and forearm were flabby and diminished in volume. Similar changes were present in the lower extremities. The increase in the volume of the soft structures of the feet was even more marked than in the hands. The increase in the size of the feet was in their width and thickness; the great toe was especially large; the heels were covered with enormous fleshy pads. The distal ends of the tibia and fibula were but slightly if at all enlarged. The clavicles were greatly increased in size and their curvature was exaggerated. The ribs were massive; their width was especially increased. An antero-posterior curvature of the cervical and dorsal regions was present. The heart was not enlarged and no murmurs were appreciable. The areas of liver and splenic dulness were not increased, and the edge of neither liver nor spleen was palpable below the costal arch. The lungs gave only negative signs. The abdomen was normal in appearance and on palpation. The thyroid gland was not increased in size. The superficial glands were everywhere slightly enlarged. The pulse did not show increased tension, and the vessel-walls were not appreciably thickened. The temperature was slightly subnormal. The daily quantity of urine was 2,850 c.c.; specific gravity, 1.011 (the patient's normal weight is about two hundred pounds). There was a faint trace of albumin and a trace of glucose by the phenyl-hydrazin test. There were a few granular, hyaline, and epithelial casts. The urea execretion was 23.05 gm.; the uric-acid excretion, 0.910 gm. The ophthalmoscopic examination by Dr. Stedman Bull showed the media to be clear. There were no hemorrhages in the fundus. The optic discs were slightly pale, and the arteries reduced in calibre. There was no pulsation. There was no disturbance of the motor apparatus. There was no sign of atrophy of discs. The examination of blood showed: Red cells, 5,109,000; white cells, 8,000; polymorphonuclear neutrophiles, fifty-eight per cent.; large mononucleated, thirty-six per cent.; small mononucleated, five per cent.; eosinophiles, one per cent.

The patient complained of intense and constant pain over the left supra-orbital region and over the left side of the head as far back as the ear. It was sufficiently acute to prevent sleep. During the two months of residence in the hospital many drugs had been used to control the pain. The pituitary and thyroid extracts had also been employed. No relief had been obtained except by the use of large doses of morphine. A typical reaction to the tuberculin test was obtained; a single milligram was used for the injection.

A Case of Acromegaly.—This case was reported by **Dr. M. Allen Starr.** The patient was a man who had been under his observation since 1892. The case was a typical one of acromegaly, and the chief symptom complained of, as in Dr. Kinnicutt's case, was headache, which was constant over the forehead and back of the eyes, and was very agonizing and distressing. It prevented his sleeping at times, and had given his face an expression of suffering that was really pathetic. In his case, Dr. Starr said, all the bones in the body, as well as the soft parts, were enlarged. The hands and feet were enormously enlarged, and the soft portions of the skin were thickened. In addition to the general features of acromegaly, the patient had a progressive diminution in his visual fields, with beginning atrophy of both optic nerves and gradually increasing blindness. His vision was now $\frac{20}{60}$, whereas when he first came under observation it was $\frac{20}{20}$. The treatment with thyroid extract had apparently proved beneficial in this case. The value of this method of treatment was shown by the following measurements, which were made on the middle phalanx of the middle finger: In October, 1894, when the patient was first put upon the thyroid extract, the circumference of this phalanx in the left hand was 7.2 cm., and in the right hand 7.6 cm.; under the influence of this remedy the fingers gradually decreased in size until the circumference of the phalanx in both hands was 6.5 cm., a corresponding reduction in size occurring in the other fingers and in the hands themselves. The size of the hands was decreased by 1.5 cm. In addition to this the thyroid extract had given him much relief from his headaches. If he intermitted the treatment for a month or two he felt worse and his headaches became more severe. Dr. Starr said that his experiments with thyroid extract in this case had convinced him that the various preparations on the market differed very much in strength.

Dr. W. Gilman Thompson said he had seen four cases of acromegaly. The one reported by Dr. Kinnicutt was remarkable because of the enormous increase in size of the soft parts, as well as the bones—especially of the lips and tongue. In a case which the speaker saw last summer the development of the disease was very slow, and the bones attained considerable size without giving rise to much inconvenience. The patient was a clergyman: he noticed that his bones were growing larger, and he found it necessary repeatedly to buy hats and gloves of larger size. He was able to continue his preaching, although he was far from being a well man. He suffered chiefly from dyspepsia and was easily fatigued. His jaws were very much increased in size, producing separation of the teeth. His family had long noticed his changed appearance, but they were desirous of keeping his true condition from him, and on this account a very thorough examination was impracticable. Acromegaly, Dr. Thompson said, should not be confounded with pulmonary hypertrophic osteo-arthritis; in the latter disease the longitudinal diameter of the bones was increased rather than the transverse, and the bones of the extremities were affected, not those of the face, head, and thorax as well.

Dr. J. W. Brannan asked Dr. Kinnicutt if he attached any significance to the reaction to the tuberculin test in the case he had reported.

Dr. Kinnicutt said he had regarded it merely as interesting and possibly suggestive. In thirty-four recorded cases of acromegaly, with full autopsy, a microscopic lesion of the pituitary body had been found in every instance, and in the majority of the cases it proved to be either a simple hyperplasia or a tumor growth of some kind.

Dr. Kinnicutt said that as a rule a typical tuberculin reaction was obtained only in persons who have some tuberculous focus in the body. Of course such a focus might be located anywhere, but in the present case it had been impossible to locate such a focus by physical examination.

Dr. Charles L. Dana said that Brooks, in his recent pathological work in connection with this subject, came to the conclusion that the trouble was probably due to a cellular hyperplasia of the granular elements of the pituitary body; that unless this existed we might have a tumor or a destructive lesion or even enlargement of the glands without the symptoms of acromegaly. It was, of course, possible that a tuberculous or other variety of growth might irritate the gland and produce this peculiar form of cellular hyperplasia.

Dr. T. Mitchell Prudden said that the hypothesis advocated by Brooks in his admirable paper on acromegaly, namely, that the disease was dependent upon a glandular hyperplasia or adenoma of the pituitary, while most plausible and ably set forth, might still wisely be held *sub judice* until more data were at hand for proof. The Brooks hypothesis was closely bound to the wider conception of the close dependence of connective-tissue growth upon the stimulus of an hypophysis secretion. Even should this be true, it might be wise to consider carefully whether we were justified from the analogy of other organs in assuming that glandular hyperplasia or adenoma was always, or was likely to be, coincident with hypersecretion.

Dr. Beverley Robinson referred to an article on the subject of acromegaly by Drs. Walton and Cheney in the current number (December 7, 1899) of the *Boston Medical and Surgical Journal*, which contained a summary of the more recent investigations in the pathology of this disease. He said that in the earlier years of his practice he could recall cases which were probably examples of acromegaly, but which he had failed to recognize as such. The speaker said he was not aware that tuberculous changes in the pituitary body had been found in any of the cases on record: at least he had seen no reference to it in recent works on the subject.

Dr. Kinnicutt said that he had employed the extract of the pituitary gland made by an English firm in the treatment of the case of acromegaly related by him, without producing any effect up to the present date. The two-grain tablets were given, the dose being gradually increased until gr. xx. were taken in twenty-four hours. In fifteen recorded cases of acromegaly which he had collected, in which the pituitary extract was used, it had produced some amelioration of the symptoms, particularly of the headache and neuralgic pains, in about half the cases.

Dr. Dana said he had used the pituitary extract in the treatment of many diseases, but he usually gave as much as gr. lx. daily before getting any effect. It gave no results in acromegaly.

Dr. Starr said he had given as much as gr. xx. daily for some time without effect.

Dr. Robinson referred to the obscure relationship which seemed to exist between acromegaly and myxœdema. He called attention to the fact that thyroid extract, the use of which was indicated in the latter disease, had also proved beneficial in the former.

The Significance of Intraocular Hemorrhage as to Prognosis of Life.—This paper was read by Dr. Charles Stedman Bull (see page 177).

Dr. E. G. Janeway said that in former years, when he met with a case of chronic nephritis with retinal hemorrhages, especially with neuro-retinitis, his prognosis was that the patient would not live over two years. Since then, however, he had met with several cases which had induced him to be less positive upon this point. He recalled one such case in which a distinguished oculist made that prognosis, and the patient was alive seven years later. Another similar case came under his observation more recently. Dr. Janeway also referred to the intraocular hemorrhages occurring in pernicious anæmia, which were formerly regarded as very significant. A case had been reported, however, in which all the symptoms of pernicious anæmia, including hemorrhages into the retina, promptly disappeared after the expulsion of a tapeworm: so-called pernicious anæmia from tapeworm.

Dr. Robinson said he was recently called to see a patient, who in addition to retinal hemorrhages complained of intense headache. The question arose whether the case was one of brain tumor or chronic nephritis. The urine contained neither albumin nor casts, but its specific gravity was low. The ophthalmoscopic examination seemed to be in favor of changes in the kidney, which later developed. The speaker called attention to the fact that retinal hemorrhages might occur without interfering to any extent with vision, and that they might escape detection unless the examiner was skilled in the use of the ophthalmoscope.

Dr. Janeway reported the case of a lady who lost the sight of one eye through a hemorrhage into the vitreous, with glaucoma. She was told that she had nephritis, but the speaker said he was able to find only evidences of a calculous pyelitis of one kidney. The urine contained pus and uric acid, but he had not found albumin or casts to such extent as to prove the implication of both kidneys, although previous to that time some one else had found albumin and casts and had in consequence considered the case as nephritis of both kidneys. There was a plentiful secretion of urea. This case was still under observation. We should not be too apt, Dr. Janeway said, to attribute these eye lesions to nephritis. In one case of neuro-retinitis which he recalled the patient's urine had been collected for twenty-four hours, and its sediment was found to contain a trace of albumin and a few hyaline casts. The neuro-retinitis was thereupon attributed to advanced nephritis, and a bad prognosis was given by the oculist. The oculist himself had been dead for ten years, while the patient was still alive. The true cause of these eye lesions could not always be made out. In another case which the speaker recalled the patient had a neuro-retinitis and was treated for nephritis. The true cause of the loss of sight proved to be a syphilitic meningitis, which disappeared under treatment.

Dr. A. Alexander Smith reported the following case: A lady, while visiting in Paris, was stricken with partial blindness while seated at dinner. She was immediately afterward seen by an oculist, who regarded the case as one of probable nephritis. A distinguished French physician later found a trace of albumin and some hyaline casts in her urine, and her husband was informed that she was likely to die at any moment. Her condition was regarded so serious that a physician was requested to accompany her to this country. Since her arrival her urine had been repeatedly examined; it at first contained a trace of albumin, which soon disappeared. No casts were found. She passed sufficient urea. Her loss of sight was due to a retinal hemorrhage, from which condition she gradually improved. Previous to her visit to Paris she had spent the summer in Mexico, at an elevation of eight thousand feet, where she became somewhat anæmic, and while she was there she had a very slight retinal hemorrhage. The second hemorrhage occurred in Paris, and a third one, also slight, during a second visit to Mexico. She had since returned to New York and was still under observation. Her health was steadily improving, and Dr. Smith said he was inclined to doubt that a sufficient degree of nephritis existed to justify the hopeless prognosis given by the oculists who saw her. He thought the retinal hemorrhages could perhaps be explained on the basis that there was a moderate amount of degeneration of the blood-vessels, and that the blood-pressure at a high elevation had caused them to rupture.

Correspondence.

THE MEDICAL ASPECTS OF THE WAR IN SOUTH AFRICA.

We publish a continuation of our special correspondent's summary of the medical events of the South African war, which will enable our readers to understand what has been done by the British up to the second week in January for their sick and wounded. Of the Boer's military medical service our correspondent says: "Little is known for certain, but enough to show that in hospital and ambulance matters, as in all their other arrangement for this war, the Boers have been underrated. They have a good ambulance service and competent medical men, chiefly German by birth. I shall send you information upon the matter when there is any that is reliable. At present certain English journals give one view and certain continental journals give another, but in neither case are the accounts founded upon facts."

(From our Own Correspondent.)

The Medical Arrangements of the Field Forces.—The general arrangements of the Medical Division of the War Office, made for the first army corps despatched to South Africa, were followed in subsequent reinforcements. The equipment is in accordance with a pattern which was drawn up as recently as 1898, and to its modernity must be attributed the highly pleasing fact to all medical men that it has been found completely satisfactory. It includes, along with all ordinary surgical paraphernalia, such extra articles as acetylene lamps, Japanese air cushions, anæsthetics, antiseptics, antiseptic cases, creolin, folding darkrooms for *x*-ray work; antiseptic dressings, various; inhalers for ether, and Clover's; Murphy's anastomosis buttons (in sets); platinum studs for *x*-ray coil; anti-streptococcic serum and syringes; anti-tetanic serum and syringes; aseptic absorbent sponges (three sizes); Schimmelbusch's sterilizers.

Ten sets of Roentgen-ray apparatus were provided, since which as many more sets through private generosity have been placed at the disposal of the Royal Army Medical Corps or its voluntary auxiliaries. Two portable disinfectors, of the pattern made and patented by Dr. J. C. Thresh, the medical officer of health for the county of Essex, were sent out, one to be stationed at Durban and one at Capetown, while there were added to the ordnance equipment a large number of approved apparatus for the filtering of water and the sterilizing of milk.

The two hospital ships, the *Spartan* and the *Trojan*, were supplied with, over and above the army rations, the following additional articles: Arrowroot, cornflour, oatmeal, pearl barley, ground rice, sago, cocoatina (tins), condensed milk (sweetened), condensed milk (unsweetened), calves' feet jelly, bovril (in four-ounce tins), Liebig's extract of meat (in four-ounce pots), Brand's essence of beef, Brand's essence of chicken, Brand's essence of mutton, mutton broth, chicken broth, solidified soup, Stower's Cordial lime juice, refined sugar, pickles (various), Hennessy's three-star brandy, Scotch and Irish whiskey, champagne (in pint bottles), port wine, sherry wine, claret, Burgundy, Australian, Emu, and Hermitage, Bass' or Allsopp's beer, lager beer, Guinness' stout. The *Spartan* was provided with a full *x*-ray plant by the Duke of Newcastle, an enthusiastic photographer, and an anonymous donor did the same for the *Trojan*.

The Central British Red Cross Committee.—The relations of the Red Cross Society to the medical service of the army in Great Britain are very intimate, and during the war the work of the society in behalf of the sick and wounded soldiers has relieved incalculable misery. The British army medical service makes but little provision for the after-care of the sick and wounded, but has always been wont to depend upon the efforts of volunteers for much of the nursing, when the invalids have been deported to the base. Immediately after war broke out the Central British Red Cross Committee—the British branch of the International Red Cross Society—was placed in the pleasing position of being able to announce that the application for employment from medical men and laymen, and the offers of contribution of ambulance material, were so varied and numerous that "for the present, ample provision has been made in the direction of supplementary aid to the army medical service in the field." Colonel J. S. Young was at once sent to South Africa, amply provided with funds and material, to co-operate with the principal medical officer of the British field force (Surgeon-General W. D. Wilson) as to the best way of providing for the sick and wounded, not only of the British army, but also of the two Boer republics. The equipment of a hospital train was despatched to Durban, where Sir George White's movements foreshadowed the earliest struggles; a hospital ship was placed in preparation; nurses, over a hundred in number and all highly trained, were obtained; while arrangements were made with the St. John Ambulance Brigade to meet any requirements in connection with a supply of ambulance officers and hospital orderlies. Besides all this, the Red Cross committee took over the work of organizing all the numerous private offers of assistance to make them effective. In this way they have the responsibility of the volunteer hospital ships—the *Princess of Wales*, directly equipped by the committee, H. R. H. the Princess of Wales providing £10,000 toward the cost, and the *Maine*, equipped by the generosity of American ladies in London; and the volunteer field hospitals, viz., the Portland Hospital, the Langman Hospital, the Sivewright Hospital, and the Imperial Yeomanry's Hospital. The *Princess of Wales* started from London at the beginning of December, and took a month to get to the Cape, as an unfortunate breakdown at the beginning of the voyage detained her some days in the Thames. Major A. Hickman-Morgan, D.S.O., a retired member of the Royal Army Medical Corps, went out on the *Princess of Wales* as senior medical officer, having under him one military and three civilian surgeons. The ship contained about one hundred beds all told, and was staffed in addition by four nursing sisters, seventeen privates of the Royal Army Medical Corps, and twenty-three members of the St. John Ambulance Brigade—to act as ward orderlies, compounders, storekeepers, etc. The *Maine*, which followed three weeks later, contained provision for two hundred and twenty patients, the Royal Army Medical Corps and the St. John Ambulance Brigade supplying the service. Colonel Hensman, R.A.M.C., sailed on the *Maine* to represent the War Office, while Surgeon-Major Cabell directs the medical services of Dr. George Eugene Dodge, Dr. Harry H. Hodman, and Dr. Charles H. Weber.

The Size of the British Medical Force at the War.—The size of the medical establishment sent out by Great Britain becomes of particular interest because it has been able to cope with disasters which were clearly not expected by the British War Office. Had the campaign proved the pleasant saunter to Pretoria which some amiable officials seem to have believed that it would, the number of medical men, bearers, and Army Service Corps sent would have appeared unnecessary, but, as circumstances fell out, all were wanted. With the original force there were sent, all told, two hundred and eighty-two medical officers of the Royal Army Medical Corps, sixty-eight civilian surgeons, fifty-six nursing sisters, twenty-eight quartermasters (R.A.M.C.), and twenty-eight hundred and fifty Army Service Corps for transports and nursing duty, making a total of thirty-two hundred and eighty-four. The very small number of female nurses is accounted for by the fact that the War Office will not allow women to assist in the field hospitals. This force was afterward increased by one hundred medical officers and about fifty civilians, while the private field hospitals have contributed some twenty more medical men with a due quantum of lay assistants. The complete total is now over thirty-five hundred, and more are going out.

The General Hospitals.—The first general hospital arranged at the base was at Wynberg. Wynberg is a beautiful suburb eight miles from Capetown, and the large permanent barracks were requisitioned as a hospital to accommodate five hundred persons. The building stands upon an ideal site overlooking a lovely country interspersed with fine residences. The medical officers, thirty-six in number, are put up in the vacant married men's quarters of the barracks, while the officers' quarters are occupied by the nursing staff. Lieutenant-Colonel Hodson, R.A.M.C., was placed in charge of the surgical side, and Major Barnes, R.A.M.C., of the medical side, the whole being under Surgeon-General Wilson. Completely equipped operating-rooms were soon in readiness, while Sir George White's early operations provided patients almost as quickly. The Wynberg Hospital is in communication with the Cape Town forces under Methuen, Gatacre, and French by the railway, upon which a hospital train service was immediately established; and with the Natal forces under White and Buller, by a service of transports from Durban. The first batch of wounded to arrive in the hospital were brought by the transport *Jelunga* from Durban, and consisted of ninety-five men who had been engaged in the battles of Glencoe and Dundee in the third week of October, and who reached Wynberg at the beginning of November. Almost immediately afterward the *Sumatra* arrived at Cape Town from Durban, bringing two hundred more wounded. Most of the first wounds were of a trivial nature, wounds of the forearm and thigh predominating; but had not the Royal Army Medical Corps, within the short space of four days from the arrival of the plant at Capetown, organized to its completest detail a general hospital, undoubtedly some of these cases, which under prompt treatment recovered immediately, would have gone to the bad. The *x*-ray apparatus proved invaluable for the detection of bullets, and only one amputation was necessary in the first lot of patients; and in a great number of cases the ordinary field dressing proved sufficient to bring about complete healing. By the first week in December No. 1 General Hospital was full, for Lord Methuen's advance northward to the relief of Kimberley was signalized by three battles in one week, all of them frontal attacks. In the first two the British were successful with considerable losses, though an insufficiency of cavalry (and some say, openly, an iniefficiency of tactics) prevented them from utilizing their victories. In the third, the fight at Modder River, the relieving force was checked with great slaughter. Certain Highland regiments lost thirteen per cent. of their strength, and hospital trains brought relays of terribly wounded soldiers down to Wynberg. The medical staff here were by this time reinforced by nine civilian surgeons, mostly fresh from the best class of hospital work; and the plant for No. 2 General Hospital having arrived, accommodation was quickly provided for twelve hundred sick and wounded. At the same time the *Spartan* brought more wounded round from Natal.

Modern Bullet Wounds.—The surgical lesson to be learned from the war became clear as soon as the general hospitals at Wynberg, as well as the stationary hospitals behind the fighting columns, became full of seriously wounded men. The lesson is that the modern bullet, with its small calibre and enormous velocity, does not leave behind it the after-effects of the old-fashioned French chassepôt, or the Martini-Henry. The wounds of both the Mauser bullet used by the Boers, and the Lee-Metford used by the British, have generally small entrances and exits, while their tendency is to heal like clean cuts by first intention. Truly wonderful stories, vouched for by Sir William MacCormac, president of the English Royal College of Surgeons, and serving in the Cape as chief surgical adviser to the army, as well as by the surgeons of the Royal Army Medical Corps, have already been published. Men shot through the brain have been only temporarily inconvenienced; the abdomen has been pierced from before backward and from side to side, and recoveries have ensued; the bladder and the stomach have been traversed and the men have continued to charge! It is abundantly clear that in a long campaign a man might be shot half a dozen times, and half a dozen times return to duty as good a man as ever.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE WAR—INCREASE OF INFLUENZA—THE REGISTRAR GENERAL'S OFFICE—EXCISION OF VESICULÆ SEMINALES—HYSTERECTOMY FOR FIBROIDS—RUPTURE OF THE UTERUS—SOME RECENT DEATHS.

LONDON, January 12, 1900.

THE war is naturally the most absorbing topic. Amid our many errors and shortcomings the one bright spot has been the medical department, which has done nobly at the front and at the base. Its devotion ought to go far to abolish the mischievous military jealousy which might have paralyzed it—did in one sense, for the War Office has been obliged to engage large numbers of "brave civilians" to take places rendered vacant by its own fault. It is the old story—unready in every department while the authorities were studying braid and buttons. The anger of the country is but feebly expressed in the newspapers, severe as are their criticisms. A clean sweep of the War Office is hoped for.

More consulting surgeons have gone out, and further surgical aid is being scratched together. Nothing could well be more condemnatory of the authorities, who ought to have been prepared with the full complement of army surgeons for the work, whereas they had numerous vacancies in the staff, which was known to be too small, and so were obliged to ask for civilians' help.

Among the numerous kindly efforts to succor the sufferers is the undertaking of doctors at home to attend gratuitously the families of soldiers on service. It is not likely any such would have had any difficulty in obtaining all they might need, but I cannot feel sure that it is wise for the British Medical Association to endeavor to organize such assistance, and at the time when so many complaints are made as to the encroachments of the public on medical service. The profession has always been too ready to extend its charity, and might have been trusted to act in such cases without any organized arrangement to do so.

The epidemic of influenza steadily increases and looks like lasting longer. From the royal household as from the most crowded slums the news is the same—the "flue" prevails. The deaths last week in London rose to three hundred and sixteen and the deaths from the class of respiratory diseases to twelve hundred and twenty-one. In the epidemic of 1892 the highest number in a week reached five hundred and six. In 1895 it was four hundred and seventy-three. The London total mortality for last week exceeded the average for ten years by more than eleven hundred. From the country come similar reports. Ireland, Scotland, and Wales are suffering too. Nottingham is very heavily stricken, eight thousand cases being said to be down in the town yesterday. At Northampton half the factory hands are absent, and the same tale comes from other places, showing that the epidemic is very widespread.

As the registrar-general's office will shortly become vacant, there is much speculation as to whether the government will have the courage to appoint the superintendent of statistics to succeed him. The latter is a medical man. Probably you may be under the impression that the chief is also. Not at all; his post has been the best paid, but with little to do except to indorse his subordinate's statements. I hope the sinecure will be abolished and the medical man promoted to continue his valuable work with the honor of the chief office.

On Monday, at the Medical Society, Mr. M. Moullin related two cases of young men with tuberculous disease of the epididymis extending upward, for which he had removed the vesiculæ seminales, and he advocated the operation in all cases in which the vesiculæ could be felt per rectum. Very little hemorrhage occurred in either case. In one a small urinary fistula remained for several months. Mr. Edwards and Mr. Wallis considered the operation less simple than had been represented, and a modification of Kraske's operation was suggested.

Dr. Gow then reported his results in hysterectomy for fibroids, showing a mortality of about two per cent. —one death in forty-seven cases. With so low a rate, Dr. Blacker said, many operations might be undertaken, but when adhesions existed the cases were more serious. He described a case in which he had been unable to remove the tumor on account of extensive adhesions. Mr. Wallis complimented Dr. Gow on his results, which he thought largely due to the simplicity of his procedure.

Rupture of the uterus was the subject of some discussion at the Obstetrical Society on the 3d inst. Dr. H. Spencer began it by relating four cases which he had successfully treated by packing the tear per vaginam with iodoform gauze. These four cases are the only ones he had thus treated, and the only cases he had known to result in recovery. He had seen about eight others, and they ended fatally, either from shock and hemorrhage or later from sepsis. In two cases he performed abdominal hysterectomy. By way of bringing out the views of others he formulated his views thus: (1) Abdominal section is rarely required, and that almost solely when the fœtus has passed partly or completely into the peritoneal cavity. (1) Abdominal hysterectomy is hardly ever necessary; when the broad ligaments are so much damaged as to endanger the vitality of the uterus, vaginal hysterectomy should be performed. (3) All incomplete tears implicating the broad ligament, also most complete tears, should be treated by packing the rupture per vaginam with iodoform gauze, after removing clots and fluid blood.

The president, Mr. A. Doran, remarked that absorption of iodoform might produce a very rapid pulse, leading to a suspicion of sepsis, a point to remember in these cases, as well as when the gauze drainage is used after ovariotomy.

Dr. Horrocks said that rupture confined to the cervix and broad ligament was much less serious than when the peritoneal cavity was opened. In one he put in two stitches and packed with sal-alembroth gauze, which was renewea under anæsthesia every twelve hours for three days, then once a day. In another case he opened the abdomen and stitched the tear. In aseptic cases he saw no objection to sewing up the wound. He did not think hysterectomy was ever advisable, and he thought sterilized gauze as good as the iodoformed.

Dr. Lewers had a case in which the rupture extended through the posterior wall into the peritoneum. He packed with iodoform gauze. The patient recovered after a very critical time. He had used the gauze often in abdominal sections and observed the rapid pulse from absorption. He attributed it to an extra percentage of iodoform in some samples. He found carbolic gauze as good.

Dr. Handfield-Jones said much depended on whether rupture was complete. In thirteen cases lately reported from Vienna packed with iodoform gauze eight were complete and all were fatal; five incomplete and all recovered. Lateral tears into the broad ligament generally recovered whether treated by packing or simple aseptic douching.

Dr. Herman advocated packing for most cases, but if the packing could not be passed right up to the top of the rent the uterus should be removed through the vagina. Dr. Spencer had given the useful suggestion to pass a large tube through the rent in order to evacuate the blood in the peritoneal cavity.

Dr. Drummond Robinson had packed two cases; one patient died; the other recovered and had since borne a child. In another case he intended to pack an incomplete rent, but on going next day to do so the patient was so much better that he did not, and she recovered.

Dr. Spencer, in his reply, said most of the cases were, he believed, incomplete. He did not approve of repacking every twelve hours—the gauze should be left for three or even six days. He did not think aseptic gauze would remain sweet, and he therefore considered it not so good as iodoform gauze.

Among recent deaths are the following:

Dr. Gardner Dudley, consulting physician to the Metropolitan Hospital and the North London Consumption Hospital, died on the 2d inst., aged seventy-two years. He was a Cambridge M.D. and M.A., a cultured gentleman, and it was a pleasure to meet him.

Mr. George Taylor, justice of the peace for Norfolk, who had for some years retired from active work, died on the 6th inst., aged eighty-two years.

Mr. Henry Thompson, surgeon to the Hull Infirmary, died on the 28th ult., aged only forty-nine years.

Dr. Gimson died suddenly at the bedside of a patient, from the rupture of an aneurism of the aorta.

Dr. George Elder, one of the younger teachers in the Edinburgh School, only thirty years of age, died on the 6th inst., from influenza. He was joint author with Dr. Fowler of a "Manual of Diseases of Children."

Surgeon-Major Alexander Grant, honorary surgeon to the Queen, died at the age of eighty-two years. He was retired since 1869, after an honorable Indian career.

Deputy Surgeon-General David Cullen, who also saw service in India, as well as in the Crimea, being present at the taking of Sebastopol and Lucknow, died on the 4th inst., aged sixty-seven years.

Dr. W. J. Belcher, of Bandon, died on the 29th ult., aged sixty-two years, from the effects of carbolic acid put in mistake into a draught he mixed for himself. Medical friends hastily summoned reached him only to find him dead.

Dr. Robert Robinson, physician to the City and Consumption Hospitals, died at Liverpool, aged fifty-eight years.

HOSPITAL AND DISPENSARY WORK IN KOREA.

To the Editor of the Medical Record.

Sir: The main difference in the practice of medicine and surgery out here in Asia, and in America or Europe as I have had to do with it in all these places, consists mainly in the very small financial outlay we are allowed to work on. I am writing of what is essentially charity work and carried on as an acknowledgment of the obligation, which is one of the general results of Christianity, to provide systematically for the sick, the sorrowing, and the very poor. This obligation, however, doesn't press very heavily when it comes to people in America or Europe providing for the natives of Africa or Asia, and so $500 a year is a big sum to expect, for my average for the past three years from the United States has been but $400. And with this, all expenses but my own salary, which is excepted, must be met, and of course we have to bring our little dispensaries and hospitals down to a standard of which this is the basis. But even with this, much can be done. One's surgical work is limited only by his ability, which the natives soon recognize, and by the appliances and facilities provided. This is my experience based on thirty thousand patients.

The lack of money drove me into eye surgery as a sort of specialty, for I found that the easiest, cheapest, happiest, and most effective branch I could turn to. During a cholera epidemic I turned specialist on that, but since then eye surgery has taken my best efforts, though the plague is threatening these shores, and, if it comes in, I'll have to neglect my eye work and see what there is to be learned clinically in that.

Taking a few notes, somewhat at random, from the past year's work, we find that in December, 1898, nine cataract operations were done. In one the lens became dislocated, and after several ineffectual attempts to get it out with the wire loop the eye was bandaged and the patient allowed to rest. Next day on removing the dressings we found that spontaneous expulsion had taken place, for there lay the lens in the dressing. In another of these cases the same thing happened, but we got the lens easily with the loop. In yet another very excessive bleeding, with gaping of the incision and loss of the aqueous, took place. Everything appeared normal and the operation seemed all right, but a few hours after severe pain and excessive hemorrhage took place. What made it more marked was that exactly the same result followed the operation in the other eye; thus showing a peculiarity in that patient. Notwithstanding all this, good results were obtained in all nine cases.

I amputated the forearm of a man aged sixty-three years, and very nearly lost him by the accident of the ligature slipping off the artery. It was discovered by feeling for the pulse in the remaining arm, and finding none. The patient had not been taken off the table, but the stump had been bandaged. The saturated dressings were hurriedly jerked off, the wound was opened, and the spouting artery secured. A pint of saline solution was injected into the abdominal tissues, and considerably more into the rectum. A prompt reaction followed, though three weeks afterward (the man had other diseases and was in the hospital a month) a cold abscess developed at the site of the injection into the abdominal wall. Very careful precautions had been taken, and this was the result. This hypodermoclysis was used recklessly in many cases of cholera, during an epidemic, and trouble followed in but one instance, and in that the injection was into the thigh instead of the abdominal tissues.

As to the number of patients, twelve thousand a year is about the average, which includes dispensary patients, medicine buyers, and in-patients, the latter numbering two hundred and fifty last year. The total expense last year, which includes salaries for natives, support for indigent patients, drugs, fuel, and everything else, was $539.03. During the three years just past, there have been sixty-four cataract operations, one hundred and twelve iridectomies, and corresponding numbers of other such work. A medical class of seven young men is under instruction, and this is one of my important duties. It is absurd to think of making modern doctors out of them, versed as we ought to be in all the allied medical sciences; so I aim simply, after three or four years, to make fairly good druggists, expecting them to prescribe and treat cases, as must necessarily be the case in the evolution of the natives into "doctors."

The main object of these little institutions, however, is not charity, but in the eyes of those who have much to do with the voting of funds, etc., they are "philanthropic institutions limited by the possibility of their evangelistic utilization and influence"—a sentiment expressed by the words, "A small development of such work contributing powerfully in the direction indicated is better than a large development of but feeble or indirect evangelistic influence."

This is the *sine qua non* which we work on, though there was nothing of that spirit shown by the Good Samaritan when he picked up the man who had fallen among thieves.

The economic value of the services rendered to the natives here, last year, which was made possible by the $539.03 from the United States of America, was, estimating on a minimum basis, over $100,000.

J. Hunter Wells, M.D.

Pyengyang, Korea.

Medical Items.

Quarantine Regulations to Insure Safe Scientific Passenger Traffic from an Infected Locality to a Non-Infected One.—The following rules are suggested by Dr. Edmond Souchon (*New Orleans Medical and Surgical Journal*) for the successful conducting of passenger traffic in epidemics, especially yellow fever: 1. Persons from an infected locality wishing to go to non-infected localities shall send to the railroad depot, eight hours previous to the departure of the train, a suit of clothes and their baggage, which shall be disinfected by the officers of the United States Marine Hospital Service. 2. They shall be present at the railroad depot one hour before the hour of departure, to change the clothes they have on for the suit disinfected under the supervision of the said officers. 3. They shall be given a certificate to that effect. 4. They shall then be admitted to a seat in a disinfected coach. 5. The baggage shall be checked and placed in a disinfected baggage-car. 6. The health officer of the locality to which they are going shall be informed of their coming by telegraph. 7. Upon their arrival at the point of destination they shall be met by the health officer or shall at once report to him. 8. They shall present themselves to him for inspection in the morning and in the evening for five consecutive days. 9. A bond may be required of them to insure their appearance, or they may be placed under the surveillance of a special officer. 10. If they have been well all that time they will then be free to go anywhere and everywhere. 11. Should they present any symptoms of fever they shall at once be isolated and be treated scientifically to prevent infection. 12. By thorough disinfection of all that comes from the patient as soon as it leaves him or has touched him, the disease will not affect any one else around him nor infect the household effects nor the premises. 13. As soon as the patient has recovered he must be disinfected, and also all his effects. 14. Also the nurse. 15. Also persons and things which have been in the room and the house. 16. Also the premises, yard, privies, and gutters. 17. All this must be done according to the instructions to the medical inspectors. 18. Non-immune persons who had been in the house or on the premises must also be kept under observation for five days after the disinfection of their clothing and effects.

The Sensory Capacity of the Female Genitals from a Forensic Point of View.—A midwife in Breslau some years ago was arrested charged with procuring an abortion by passing an "instrument" and causing the "waters" to come away; the fœtus being expelled two days later. Experts called were of the opinion that the patient could not be sure whether the instrument was passed into the vagina and uterus, or into the bladder. Dr. Calmann (*Archiv f. Gynäk.*, Bd. lv., Heft 2), who has recently investigated this subject of genital sensibility, concludes as follows: 1. The sense of localization is very defectively developed in the female urino-genital system; the local differentiation between the urethra, bladder, and the vagina is quite uncertain; and a similar sense of locality between the vagina, portio, and uterine cavity does not exist at all. 2. The sense of touch, especially of the portions of this region which lie above their respective entrances, is likewise defectively shown. All judgment is absent as to the length of an object introduced; the thickness is fairly well recognized, but no correct estimate of it is made with certainty. There is great obscurity as to the form and other characters of objects introduced. The number of objects introduced into the vagina is often falsely given. There is no sense of touch in the portio vaginalis and the uterus. 3. The sense of pressure is somewhat well developed in the urethra, in the vagina it is very feeble, and in the uterus and outer surface of the portio it cannot be demonstrated. 4. The sense of temperature is also fairly good in the urethra. In the vagina it is feebly developed, especially toward the hotter degrees of temperature. It fails entirely in the uterus and portio. 5. Sensation of pain is quick in the urethra and in the vagina; in the portio and cervical canal it is only moderate, in the uterine cavity it is often marked. This forms the only subjective difference between the uterus and vagina. 6. Vaginal douches and the customary disinfectants diminish the sensibility of the vagina.

The Cost of Sickness.—The records kept in Germany in regard to sick insurance, which is now compulsory upon workmen, are beginning to show how serious a strain sickness produces upon a country. It appears that nearly eight millions of persons in Germany subscribe to the Krankenkassen, that is to insure against sickness, and that in 1898 one-third of this number reported illnesses of one sort and another, the average duration of sickness being seventeen days. Now if we reckon wages at only fifty cents a day this comes to a loss of more than twenty-two and one-half millions of dollars a year in wages alone, besides what has somehow to be provided for food, physic, and maintenance. This, of course, is among working people during the working period, which is presumably the most healthy part of their lives.—*London Hospital.*

Nerve Suture and Sensation.—In the French supplement to *La Grèce Médicale*, Dr. Petridis relates a case of secondary suture of the radial nerve after eighteen months, in which restoration of sensibility was practically instantaneous. The patient had been wounded by a bullet in the forearm during the recent Greco-Turkish war so severely that the surgeons proposed to amputate, and would have done so "had not the Greek troops been obliged to retire." The wound left a painful cicatrix with atrophy and ankylosis of the arm and hand, especially the thumb, index, and middle finger. There was entire loss of sensation over the region supplied by the radial nerve. After operation, while the patient was still on the table and recovering from the anæsthetic, Dr. Petridis pricked with a needle the dorsal surface of the hand in a spot which had been totally anæsthetic for eighteen months, and the patient at once responded. Four hours later sensation over the affected part was almost normal. The writer gives a summary of other cases in surgical literature showing the capricious and still unexplained manner in which sensibility returns after suture of divided nerves. Perhaps the most interesting is an observation of M. Remy in two cases of division and suture of the median, in which touching the tip of the index finger gave rise to sensation in the thumb and middle finger respectively: "This transformation of sensibility is not transitory, for I have observed it more than a year after the commencement. Paget has published a case of the same kind."—*Medical Magazine.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended January 26, 1900:

		Cases.	Deaths.

REMARKS ON SUBPHRENIC ABSCESS; WITH A REPORT OF THREE CASES.[1]

By A. A. BERG, M.D.,
NEW YORK,
ADJUNCT SURGEON TO MT. SINAI HOSPITAL.

To Leyden belongs the credit for calling attention to suppuration in the subphrenic region, as distinct from purulent collections above the diaphragm. In his descriptions he had reference to large cavities filled with gas and pus, lying underneath the diaphragm, but pushing the latter upward, so as to occupy relatively the lower thoracic region and giving physical signs somewhat resembling pyo-pneumothorax. In contradistinction to the latter affection, he named this new one pyo-pneumothorax subphrenicus. From a number of cases that came under his observation he sought to establish a clinical basis upon which to rest the differentiation of the supra- from the infra-diaphragmatic suppuration. His observations made in 1880 have been added to from time to time, notably by Barlow and Pfuhl, but, although it is almost a decade since his classical descriptions of this affection appeared, our differential diagnosis is to-day by no means perfect.

The name which Leyden gave to this affection, viz., pyo-pneumothorax subphrenicus, would lead us to infer that all these abscess cavities are gas-containing. This condition does not, however, always obtain, for very many of these subphrenic abscess cavities are non-gaseous. This variance in the presence of gas, along with the pus, necessarily causes a variance in the physical signs that suppuration in this region would give. To arrive more easily at a basis upon which to rest our clinical diagnosis of these abscesses, we must therefore divide the subject into two main classes: (*a*) Those abscess cavities that contain gas and pus; (*b*) those that contain pus alone. Again, in either class we must consider whether or not there has been a secondary involvement of the pleural cavity.

I shall consider each class separately, pointing out the physical signs that are usually obtained from the presence of such an abscess, and attempt to show how to differentiate subdiaphragmatic suppuration from the other affections with which it is likely to be confounded.

First, as to those subphrenic abscesses that contain gas. The classical signs that such an abscess would give are as follows: An enlargement more or less marked of the lower thoracic region, with downward displacement of the liver and spleen, so that these viscera become distinctly palpable. Fremitus is diminished, or even absent, over the lower part of the chest on the affected side. Percussion of the chest from above downward gives a note, increased in pitch and intensity above, and merging below into a full tympanitic sound; splenic and hepatic dulness is more or less obliterated. On auscultation there is normal vesicular murmur at the apex, with increased or bronchial breathing just below it, and still further below amphoric breathing, or metallic tinkle, or both; succussion is present; the apex beat is but little, if at all, displaced. An abscess giving rise to such physical signs can be confounded only with pyo-pneumothorax, in which the physical conditions are of the same nature as obtain in subphrenic pyo-pneumothorax.

Leyden in his earliest papers indicated the lines on which our differential diagnosis can be made: (*a*) The previous history of the patient, which points to a primary trouble somewhere in the abdomen, and not in the chest. (*b*) The absence of cough and expectoration, or of any pulmonary lesion which could give rise to a pyo-pneumothorax. (*c*) The presence of normal vesicular murmur, with normal fremitus at the apex, with a sharp line of differentiation from the amphoric breathing below; furthermore with deep inspiration the line of normal breathing descends to where the amphoric breathing had been. (*d*) The very slight displacement of the apex beat. (*e*) The rather inconsiderate bulging outward of the intercostal spaces, and the absence of immobility of the chest wall. Neuser has added the observation that the basal line of thorax dulness is crescentic, with the convexity downward, instead of horizontal as in encapsulated pyo-pneumothorax.

When we come to consider those cases of gas-containing subphrenic abscess that have become complicated by the presence of a pleural effusion, we find that there have been added to the physical signs of the subphrenic abscess those of fluid above the diaphragm. This would seem to render the differentiation of these cases from simple pyo-pneumothorax much more difficult; but the acute observations made by Barlow in such a case that came under his observation have rendered the diagnosis very much simpler in those cases in which the pleural effusion is free, and especially if it is serous in character. For it must be remembered that the pleural effusion may be either serum or pus, that it may be free or encapsulated, and that the pus may or may not have the same characteristics as that in the subphrenic cavity.

I shall consider the simplest complication first, viz., the presence of free fluid, whether serum or pus, above the diaphragm. The physical signs by which Barlow has enabled us clearly to differentiate such a status from pyo-pneumothorax are as follows: (*a*) In addition to the physical signs I have detailed above, due to the subphrenic abscess, there were undoubtedly the signs of a pleural effusion lying above this gas-containing abscess cavity; (*b*) the maximum intensity of the amphoric resonance and breathing was underneath the false ribs. If these observations are added to those made by Leyden, and which I have just quoted, viz., the previous history of the patient and the absence of any pulmonary lesion that could have called forth a pyo-pneumothorax, the diagnosis is rendered comparatively simple; and it is rendered more certain, as was also pointed out by Barlow, by exploratory aspiration. For if on aspirating through one of the upper intercostal spaces we draw out clear serum, and on aspiration at a lower level pus, the probability is very strong that the diaphragm is separating these two cavities; for it is very unlikely that a membranous septum in the pleural cavity could be so complete as to separate the latter into two compartments, the one containing pus and gas and the other serum.

---

[1] Read before the Medical Association of Greater New York.

When the pleural exudate is encapsulated, the difficulty in reaching a diagnosis is considerably increased. Should the exudate happen to be serum, exploratory aspiration, with the result of finding serum at an upper intercostal space and pus at a lower level, would help us very much; but should pus be obtained from both punctures, we would have to depend for making our diagnosis upon the two points so strongly insisted upon by Barlow, and which I have already mentioned, viz., "the level of maximum intensity of the amphoric resonance and breathing," which, in a pyo-pneumothorax subphrenicus, is underneath the false ribs; and, secondly, that "the signs of fluid are distinctly above a cavity containing both gas and pus."

This brings me to consider the second class of subphrenic abscess, viz., those cases in which there is no gas within the abscess cavity, but only a focus of suppuration in the subphrenic spaces. Such abscesses may even be due to ulceration of the hollow viscera, in which the communication with the viscus has been shut off by an adhesive inflammation around the ulceration, before perforation has really occurred. In this class of cases it is not the differential diagnosis alone that presents the difficulty, but the actual diagnosis of the existence of the abscess itself. For it is very evident that there may even be quite a considerable collection of pus in the subphrenic region, without giving any physical signs whatsoever; and the frequency with which we fail to detect subphrenic abscess in obscure cases of suppuration should be a warning to us to have constantly in mind the possibility of the existence of pus in this region, without any distinct signs pointing thereto. Very often these cases of subphrenic abscess remain undetected until they have ruptured into the pleural cavity or caused a secondary empyema.

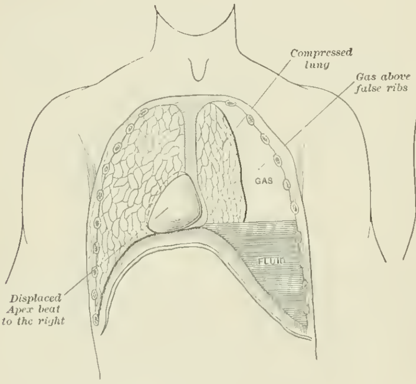

Fig. 1.—Left Pyo-Pneumothorax. (After Maydl.)

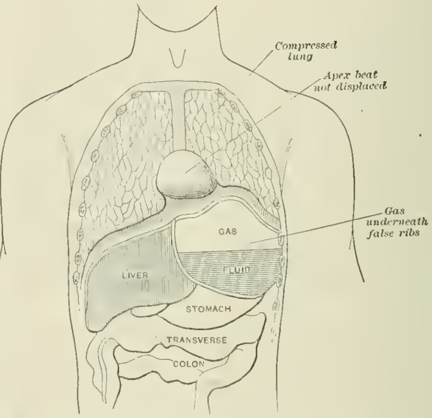

Fig. 2.—Left Pyo-Pneumothorax Subphrenicus. (After Maydl.)

When they have become large enough to give rise to physical signs, these must be sought in the chest rather in the abdominal cavity. Inspection of the affected side may reveal a slight bulging or œdema of the lower thoracic region. The liver or spleen is slightly displaced downward and can be palpated. There is very likely to be a distinct area of pain and tenderness underneath the false ribs. Percussion shows "dulness" over the lower thoracic region, which may be more or less marked. The breathing is not much changed in frequency, but the lung over the abscess shows the signs of compression, which diminish with a deep inspiration. These physical signs, with a pus temperature, and an absence of any preceding pulmonary history, or of any cough or expectoration, are sufficient to enable us to make the probable diagnosis in most cases.

When such an abscess has excited, either by rupture or by its vicinity, an inflammation in the pleural cavity, with a resulting exudation into that cavity, the diagnosis is very much more difficult. Here we have to depend upon the history, which points to an antecedent abdominal inflammation, and upon aspiration, which, if the needle withdraws pus at a lower level and serum at an upper intercostal space, decides the diagnosis, and to the manometric test of Pfuhl.[1] Should there be pus both above and below the diaphragm, our diagnosis is very difficult and must be decided by the extent of the downward displacement of the liver and spleen, and by the observation of the lowest level at which we can aspirate pus.

This variety of subphrenic abscess must be differentiated from an abscess of the liver, that causes the latter to be enlarged upward and backward; and from a splenic abscess that bulges the latter upward. This differential diagnosis is most frequently impossible, for the same causes that call forth an abscess of the liver and spleen also give rise to subphrenic suppuration. The physical signs that are to be elicited in either case are identical in character, and unless there is a distinct history pointing to a liver or splenic abscess, or the pus on microscopical examination shows the presence of liver cells, the differential diagnosis cannot be made.

I have gone thus carefully into the differential diagnosis of subphrenic abscess, because a knowledge of the exact location of the pus, whether it is above or below the diaphragm, has considerable influence upon the lines of our operative attack. I shall call attention again to this, when I consider the treatment of subphrenic abscesses.

---

[1] The manometric test of Pfuhl is based upon the negative pressure existing inside the chest during inspiration, and the increased pressure therein during expiration, and the very reverse of these conditions in the abdominal cavity, viz., an increased pressure during inspiration and a diminished pressure during expiration. Therefore if a cannula connected with a manometric tube is inserted into an abscess cavity above the diaphragm, the mercury in the tube will fall with inspiration and rise with expiration on account of the physical conditions named above; and vice versa, a manometric tube connected with an abscess cavity below the diaphragm will show a rise of pressure during inspiration and a fall of pressure during expiration.

It might be of interest here rapidly to run over the etiology of subdiaphragmatic suppuration. Here again we can divide our subject into the two same classes as before, viz., those abscesses that contain gas and those that are non-gaseous. The gas which is present in a subphrenic abscess arises from a perforation of one of the hollow abdominal viscera, or from a secondary rupture into a bronchus, or from gas-producing bacteria. It must be remembered, however, that a subphrenic abscess may be due to ulceration of one of the hollow viscera without the presence of gas in the abscess cavity, as the visceral fistula may have been closed by adhesive inflammation to neighboring organs before actual perforation has occurred.

Gas-containing abscesses may be due to (*a*) wounds, ulcerations, whether benign or malignant; inflammations, with ulcerations, of any one of the hollow viscera, as the stomach, duodenum, intestine (small or large), or appendix; (*b*) wounds or ulcerations of the bile ducts. (*c*) Simple subphrenic abscesses may become gas-containing, from perforation into a hollow viscus or into a bronchus.

Non-gaseous subphrenic abscesses are (*a*) usually metastatic—the primary focus being situated in any part of the body, but most frequently in the abdominal cavity; (*b*) secondary to liver or splenic abscesses or perinephritic abscesses; (*c*) due to the echinococcus; (*d*) traumatic in origin; (*e*) secondary to disease of the costal cartilages or vertebræ.

Treatment.—We can dismiss this with a few remarks. The only therapeutic measure is operative procedure to evacuate the pus, both below and above the diaphragm, when the latter is present. As regards the technique of the operative attack upon the subphrenic pus, in case the pleural cavity is normal I prefer to resect the tenth rib, from the anterior axillary line to the scapular line. This takes the wound below the limits of the pleura, and if it is necessary to gain more room I carefully strip up the costal pleura from the eighth and ninth ribs, resect these ribs to a similar extent as the tenth, and then peel up the pleura from the diaphragm. I prefer this low point of attack to the higher trans-pleural operation, because we can thereby avoid invading the pleural cavity. In the trans-pleural operation, I have found great difficulty in walling off the general pleural cavity, so as to prevent its infection; and the suture of the diaphragmatic pleura to the costal pleura, with the view of shutting off the pleural cavity, I have found to be very unsatisfactory, because the sutures are firstly very difficult to apply, and, when in place after considerable difficulty, they invariably tear out when an attempt is made to tie them. After the pleural layers have been stripped upward, the diaphragm is incised and the pus evacuated. Drainage is established by tube and gauze, and an aseptic dressing is applied. Should the pleural cavity have been opened, the operator must be on his guard for the evil consequences of the acute collapse of the lung, and be ready to use artificial respiration, or, even better, the "Fell-O'Dwyer" apparatus for artificial respiration, until the pleural cavity can be closed by packing or sutures. Should there be serum in the pleural cavity, this will be found to disappear spontaneously, on removing the primary cause of trouble; but when pus is present this must be evacuated, preferably by resection of a rib. I would prefer to drain the cavities by separate openings, retaining the lower incision for the subphrenic space, and using a higher one (over the seventh rib) for the pleural drainage.

With the preface of these remarks on this subject I beg to submit to your attention the clinical records of the three following cases that came under my care during the past summer:

Case I.—Hannah D——, sixty years of age, a housewife, was admitted to the medical service of Dr. Brill, at the Mount Sinai Hospital, on May 10, 1899. Her family history was negative. She had had rheumatism several times. There was no specific history; she had passed the menopause twelve years previously. Her present history began three months before admission, with fever, chilly sensations, and general weakness. At the same time she became short of breath, and had occasional attacks of cardiac palpitation. Urination had been scanty and painful. The feet and legs had been swollen since the onset of her illness. She had had some cough and muco-purulent expectoration; there had been loss of appetite and constipation.

On admission to the hospital the physical examination gave the following data: A very obese woman, pale and flabby, with moist and coated tongue; pulse rate of 98, regular; considerably sclerosed arteries; temperature, 103° F.; respiration, 30–36. The lungs and heart were normal. There was a slight cough, and a very moderate expectoration. The liver and spleen showed nothing abnormal in size or position. The urine was likewise negative in pathological constituents. The patient remained in this condition, with a daily rise of temperature between 101° and 103° F.; pulse, 96–116; and respiration, 26–36. On May 17th she gave the first indication as to the site of her trouble. On this day she complained of considerable pain in the left hypochondrium posteriorly. On May 22d there were resistance and marked tenderness in the left hypochondrium. On May 24th the physical examination gave the following signs: In the left lung, fine crepitant râles at the base in the axillary line; behind, at the extreme base, there were slight dulness, slightly increased voice, roughened breathing, and marked crepitations, extending downward for three inches. The liver was negative; the spleen was displaced downward, and merged above into a hard indurated area, which extended forward to the mammary line, and downward to two fingers' breadth above the umbilicus. This area was flat to percussion and painful and tender. Doctor Brill aspirated this mass in the axillary line, tenth interspace, and withdrew a syringeful of yellowish pus which showed no liver cells.

On May 25th the general condition was worse; the pain was intense, and her fever had been continuously between 101° and 103° F.

On May 26th Dr. Lilienthal operated upon her under chloroform anæsthesia. He first made a lumbar incision for the purpose of exploring the perinephritic tissues, but found these normal. He then made a second incision at right angles to the first one, and extending upward from its middle for about three inches. The aspirating-needle introduced directly inward at the upper limit of this second incision revealed the presence of pus. The tenth rib was excised between the anterior and posterior axillary lines; the pleural cavity was opened, and when found to be normal it was immediately closed by suture. The diaphragm was then incised, and a large quantity of pus evacuated. The pus was of a yellowish-brown color, and showed tyrosin cystals and fatty and degenerated liver cells. The cavity was drained by tube and gauze and dressed dry.

May 27th: The patient reacted well from the operation; there was a profuse purulent discharge from the wound. The highest temperature was 101.6° F.; pulse, 100; respiration, 24. The urine contained granular and hyaline casts.

June 5th: During the week the patient had lost ground. The temperature ranged between 100° and 103° F. each day; pulse, 110–130, and weak; respiration, about 40. The wound looked pale and flabby, and discharged profusely. During the next fortnight the patient continued losing ground. The temperature ran a little higher course, reaching 105° F. at times; the pulse became more rapid, 146, and there were signs of mental wandering with hallucinations. The patient appeared septic, but no other focus of pus could be found, and the wound itself appeared well drained, and was filling up with granulations. On June 25th, on the suspicion that there might be an encapsulated focus of pus in the vicinity of the wound, which had not been drained, an exploratory aspiration was made in several directions around the old wound, but with negative result. The liver, which was slightly enlarged, was also aspirated, but with like negative result.

July 1st: The patient was still in the same condition. She complained of pain and tenderness in the epigastrium, in which a marked resistance could be felt. There was also considerable ascites.

July 3d: The resistance in the epigastrium could be distinctly felt, and it was thought to be the left lobe of the liver. Exploratory laparotomy was decided upon, which I proceeded to perform at once. Under chloroform anæsthesia I made a median laparotomy in the epigastric region. The peritoneum was found intensely œdematous, and there was considerable ascitic fluid in the general peritoneal cavity. The left lobe of the liver was enlarged. The surface of the liver was smooth, and of normal consistency. Aspiration of the left lobe showed the presence of multiple miliary abscesses. Nothing was to be found in the right lobe. Nothing could be felt in the portal vein as it lay in the gastrohepatic omentum. The subphrenic abscess appeared to have no connection with any of the hollow viscera. The abdominal wound was partly sutured and drained and an aseptic dressing applied.

July 4th: The patient bore the operation very badly; her pulse became very rapid, and she died twenty-four hours later. A culture of the liver pus obtained by aspiration showed the presence of streptococcus longus.

Autopsy: A complete post-mortem not having been permitted, an examination was made through the wound by Dr. Libman, the assistant pathologist of the hospital. The report was as follows: The liver showed marked degeneration. In the left lobe were numerous miliary abscesses, varying from a pea in size to one inch in diameter, and containing thick green pus. In the neighborhood of some of the abscesses were small hemorrhages due to aspiration. The portal vein contained no thrombus. The stomach was entirely normal, with no ulceration and no connection with the abscess cavity. The spleen was moderately enlarged. A depressed white scar ran across its centre transversely. In the upper pole was a white nodule about 1 cm. in diameter. Both these seemed to be healed abscesses. The splenic vein contained a purulent thrombus. Heart: the mitral flaps had calcareous deposits. The left ovary was cystic, about the size of a large walnut.

Case II.—Becky B——, aged thirty-six years, admitted to the gynæcological service at the Mount Sinai Hospital on July 2d, with the following history: She had been confined four weeks previous to her admission, by a midwife. The day after confinement she had several chills and fever, the next day she was curetted for retained secundines. The fever continued with sweating; there was no vomiting, but a constant pain in the epigastrium. There had been no pain in the chest, and no cough or expectoration, at any time during her illness. On admission the physical examination gave the following data: Her general condition was poor, and she was slightly icteric; the tongue was moist but coated. Temperature, 100° F.; pulse, 80; respiration, 20. Lungs: anteriorly there were no abnormal signs; posteriorly, on the left side, there was dulness from the mid-scapular region to the seventh rib, with flatness below; breathing and voice were absent at the extreme base, but distant bronchial at the level of the angle, becoming normal above; there were no râles and no friction sounds. Fremitus was diminished at the angle of the scapula, but lost below. On the right side there was diminished breathing at the base, but this was less marked than on the left side. Heart: sounds feeble but otherwise negative; no displacement of the apex beat. The liver extends from the fourth space downward to two fingers' breadth below the costal margin. The left lower margin of the liver descends to a lower level than is usual. There were pain and tenderness over the gall bladder. Spleen: enlarged to percussion, but not palpable. Abdomen: muscles tense. There was pain in the right side of the epigastrium and in the left lumbar region; nothing was to be felt in the left lumbar region, but a mass could be palpated in the right epigastrium, most likely the gall bladder. The extremities were normal. The urine was normal. The pelvic organs were normal.

On July 29th, Dr. Allen, the house surgeon, aspirated through the ninth intercostal space, left side, in the scapular line, and withdrew pus. The patient was transferred to the general surgical service for operation.

On August 4th she was operated upon, in my presence, by the house surgeon, under chloroform anæsthesia. About two and one-half inches of the eighth rib, from the middle axillary line to the scapular, was resected, and the pleural cavity opened. It was found to be normal, except that the lung was adherent at its base to the diaphragm. The pleural cavity was protected above by a wall of packings, the diaphragm incised, and about a pint of pus evacuated. The cavity was drained by tube and gauze; the pleural packings were left in place, and an additional tube drain was inserted into the pleural cavity; dry aseptic dressing was applied.

August 5th: The patient reacted well from the operation, but was extremely dyspnœic, the respirations being 54 to the minute, evidently due to the collapse of the lung. The temperature was 102.4° F. at its maximum; pulse, 100–104 per minute.

August 7th: The wound was dressed. There was no empyema present, but the left lung was still collapsed, as the pleural cavity had not as yet been closed by adhesive inflammation around the packings. There was a profuse discharge from the subphrenic wound.

August 15th: The pleural cavity had become shut off by adhesions; the respirations had fallen to 24–28; pulse, 120; the temperature had fallen to 99.8° F. The general condition was much improved, and there was much less discharge from the wound, which was commencing to granulate nicely.

August 30th: The temperature, pulse, and respiration were almost normal. The wound was closing by granulations and there was very much less discharge. From now on the abscess cavity gradually contracted and filled up by granulations, and the patient made a good and rapid convalescence, being discharged cured on September 24th.

I should like here to call attention to the urgent dyspnœa produced in this patient by the opening of the pleural cavity, with the consequent collapse of the lung; also to the inefficacy of the pleural packings as a means of closing the cavity, as these were being constantly displaced by the movements of the chest wall.

Case III.—Annie R——, nineteen years old, an operator, was admitted to the Mount Sinai Hospital on August 29th, at 10:30 P.M., with the following history: She had been perfectly well until three weeks before admission, when she was taken suddenly ill, with collapse, severe general abdominal pain, and high fever, 107° F. The pain and fever continued until three days before admission, when the abdominal pain became less marked, and the patient began to cough and have pain in the left chest. The physical examination gave the following data: General condition poor; temperature, 103°; pulse, 118; respiration, 20. Lungs: In the left chest, in front there were dulness on percussion over the left supra-clavicular region, and hyper-resonance below the clavicle. There were bronchial voice and breathing at the base. In the axillary region there were dulness on percussion, and diminished voice and breathing. Crepitant râles were over the entire left chest. In the right lung, over the base posteriorly, there was slight dulness, with increased voice and breathing, and crepitant râles. The abdomen was soft and collapsed. The liver extended one and one-half fingers' breadth below the free border of the ribs. In the left hypochondrium, from the seventh rib downward, there was flatness to percussion; the spleen was displaced downward and forward, reaching to the level of the umbilicus. Beneath the false ribs was a tender, indurated mass, which extended forward to the mammary line, and merged below with the spleen. This mass gave a sense of deep fluctuation: there was no succussion. In the epigastrium was a tender, indurated mass, about the size of a small orange. There was no sign of fluctuation. The urine was acid; specific gravity 1.020; otherwise negative.

The patient was sent to the operating-room at once, and under chloroform I proceeded to operate. I first aspirated the indurated mass in the left hypochondrium, through the ninth intercostal space, and withdrew thick, extremely fetid pus. I resected the ninth rib for two inches, and found the costo-phrenic sinus obliterated by adhesions. I incised the diaphragm, and opened into a large abscess cavity, non-gaseous, containing about one pint of extremely fetid pus, a culture of which showed the presence of streptococci and bacteria coli. The spleen bulged into the wound; it was covered by a thick coating of lymph. At its lower pole was a whitish spot which seemed to me to be scar tissue. I excised a wedge-shaped piece of this for examination. The pathologist reported that it showed only the evidences of congestion and perisplenitis. The abscess was well walled off on all sides. To afford better drainage, I resected the eighth rib, and displaced the pleural layers upward. The cavity was drained by tube and gauze. Exploratory aspiration of the left pleural cavity withdrew only clear serum; this was left undisturbed. I considered the advisability of exploring the indurated mass in the epigastrium; but in view of the extremely septic condition of my own and assistant's hands, the instruments, etc., I decided to wait for further developments, rather than expose the patient to the risk of infection of the general peritoneal cavity.

August 26th: The patient had reacted well from the operation. Her temperature was 103.8° F.; pulse, 104; respiration, 30. There were frequent vomiting and muco-purulent expectoration. Examination of the blood showed a moderate leucocytosis. The wound was dressed; there was a slight amount of discharge.

August 30th: The patient's temperature still persisted, ranging from 101.8° to 103.2° F. daily; the pulse rate from 102 to 112. There were considerable cough and muco-purulent expectoration. The physical signs in the left chest still persisted, but aspiration of the left pleural cavity resulted negatively. The mass in the epigastrium was still present, but it was not tender, and there was no sign of fluctuation therein. The general condition of the patient was fair. The wound was covered with pale granulations, and there was less discharge. There was nothing to be found to account for the daily rise of temperature.

September 2d: The temperature still persisted. The sputum was examined, but no tubercle bacilli were found.

September 6th: The patient was in about the same condition: there was continued high temperature, and rapid pulse rate. The sputum was again examined and found negative. There was a trace of albumin in the urine.

September 13th: During the past week the general condition of the patient had slightly improved, but the temperature persisted, varying between 100.4° and 103.2° F. The wound looked clean and discharged very little. The epigastric mass was somewhat larger but not tender. In the right lumbar region was a round, smooth swelling, which I could displace upward; it was very tender. The house surgeon took this swelling to be an enlarged and distended kidney; I considered it to be the lower pole of a floating kidney. The urine was of a specific gravity of 1.010, and contained a trace of albumin, pus cells, and bacteria, and was alkaline in reaction.

September 14th: The epigastric mass was painful and tender, and I decided to make an exploratory laparotomy to ascertain the nature of this.

September 15th: Under chloroform I made a median laparotomy, directly over the mass. I at once opened into an abscess cavity, which was adherent to the anterior abdominal wall; the same thick pus that was contained in the previous abscess was also here evacuated. The walls of the cavity were formed by adherent coils of intestines, and the cavity reached considerably below the umbilicus. There was no visible connection with the stomach or the other abscess cavity; its extension downward suggested an appendicitis, and the odor of the pus was remarked at the first operation to be appendicular in character; but even under the anæsthesia there was absolutely nothing to be felt in the right iliac fossa, and there had been no pain or tenderness there. The cavity was non-gaseous. The abscess was drained by tube and gauze and dressed dry.

September 16–19th: The temperature fell the next day to 99° F., but rose again in the evening to 102° F., and then continued on the same plane as before. The patient's general condition was getting worse; the pulse was more rapid and feeble, and there was evidently more pus somewhere, which had not been evacuated. The right kidney was so painful and tender, and the urine contained so much pus and bacteria, that I decided to explore the kidney.

September 19th: Exploratory nephrotomy was performed under chloroform. A small incision was made in the lumbar region; the kidney was exposed and aspirated in all directions, but no pus was found. I did not open the pelvis of the organ. The wound in the soft parts was closed at once by sutures and sealed off from the abscess cavities on the left side. I then aspirated the left pleural cavity again, and drew off some very fetid pus, the odor being similar to that in the other abscess cavities. I resected a portion of the seventh rib, and evacuated about eight ounces of pus from a sacculated cavity. This was drained by tube and gauze and dressed.

September 20th: The patient reacted well after the operation: the temperature at its highest point was 101° F.; pulse, 100; respiration, 28. She took considerable nourishment; the urine was the same as before.

September 28th: The general condition of the patient had improved considerably; the temperature ranged between 98.8° and 101° F.; pulse, 100. The kidney wound had completely healed and the sutures were removed. The other wounds were granulating and contracting.

October 5th: The temperature has become almost normal. The general condition was much improved, the patient sitting up in bed. The wounds were granulating nicely. There was still some odorous discharge from the first perisplenic wound, but nothing could be felt on probing it.

October 9th: The patient was convalescing in the hospital.

Comments on these Cases.—As to their etiology. Case I.: There was no positive conclusion reached either at the operation or during the course of the illness, or at the autopsy, as to the cause of the original subphrenic abscess. As to the possibilities, there may have been an abscess of the spleen, subsequent to an infected thrombus or embolus. In favor of this there were the calcareous condition of the arteries and heart valves, and the whitish nodules in the spleen, that the pathologist thought might represent a healed abscess. If this was the primary cause, then we must suppose that there was a secondary rupture into the subphrenic space, with a resulting abscess formation there; then a suppurative thrombosis of the splenic vein, and metastatic miliary abscesses of the liver; or the thrombus may have lodged originally in the splenic vein.

Case II.: This subphrenic abscess was undoubtedly metastatic, from an infection in the uterus.

Case III.: Here again I am not positive as to the cause of the trouble. The possibilities here are: (*a*) An appendicitis which gave no signs whatever; the odor of the pus was very suggestive of this trouble. (*b*) A perforation of a gastric or duodenal ulcer. The high temperature observed by the patient's physician at the very beginning of her attack, while it would seem to oppose this view, yet does not altogether rule it out; for there may have been an adhesive inflammation around an ulcer that was about to perforate, so that when actual perforation occurred there were no bleeding and no extravasation into the general peritoneal cavity.

In both Cases I. and III. there was no primary focus to give rise to metastatic abscesses.

As to diagnosis: This should have been easily made in all three cases. In Case I. it was made by Dr. Brill, and in Case III. by the writer. In Case II. the physical signs were classical, but the high site at which pus was aspirated led me to expect rather a sacculated empyema. Had I but kept in mind Leyden's earliest points, viz., that in the absence of any previous pulmonary lesion, and in the presence of a primary abdominal trouble, we should strongly suspect subphrenic pus, I would have made the diagnosis in this case also.

As to treatment: The important point, as I have already indicated, is to avoid opening the pleural cavity. This was avoided in two cases. In the third the pleural cavity was opened and packed with gauze. The acute collapse of the lung which occurred in this case illustrates the danger of such invasion of the healthy pleural cavity, and in debilitated persons it is enough to turn the chance of recovery against our patients. I cannot lay too much stress upon this point, for the "trans-pleural" route is very frequently used in opening hepatic abscesses as well as subphrenic abscesses.

774 Madison Avenue.

Note.—In the discussion, among other remarks, Dr. H W. Berg called attention to the comparative frequency of subphrenic suppuration. In differentiating subphrenic abscess on the right side from an abscess of the liver, he laid great stress upon the "marked fixidity" of the liver in the former affection, due to the adhesive inflammation of the liver to the diaphragm, which latter organ had become paralyzed to a marked extent. In abscess of the liver, on the other hand, the liver remains perfectly movable, and shares in the movements of the diaphragm. Furthermore, as regards pyo-pneumothorax, he called attention to the extreme importance of the following physical signs: The tympanitic resonance in pyo-pneumothorax extends up to the apex of the chest, and over this tympanitic area there is an absolute absence of any respiratory murmur. In subphrenic abscess, on the other hand, the tympanitic resonance and the amphoric voice and breathing are at the base of the chest, and there are distinct respiratory murmur and voice at the upper part of the chest. In the cases of right-sided subphrenic abscess that had come under his observation, the patients had complained of pain in the right shoulder. To explain the comparatively greater frequency with which subphrenic suppuration accompanies purulent collections in the iliac fossa, he instanced the experiments which showed the free communication of the lymphatics in the iliac fossa with those in the subphrenic region.

THE RESULTS OF THE SO-CALLED CONSERVATIVE TREATMENT OF APPENDICITIS.[1]

By SAMUEL LLOYD, M.D.,

PROFESSOR OF SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

Gentlemen: When Dr. Morris, a few days ago, asked me to read a paper before you this evening, I had just been reading his reply to some of his critics in the Medical Record of December 9, 1899, and was reminded that for some years I have been following the histories of a number of patients who had been treated, in their first attacks of appendicitis, upon the theory that the disease belonged to the domain of medicine rather than that of surgery. I immediately looked over my histories, with the following results:

Case I.—A physician, who had had several attacks of abdominal pain, never diagnosed as appendicitis. In 1885, he had a severe attack and was treated by means of calomel and opium. He suddenly collapsed and died in a few hours. The autopsy revealed a perforation of the vermiform appendix, through which a small concretion had escaped. There was no attempt at "walling off" of the peritoneum, so that the opening communicated directly with the peritoneal cavity.

Case II.—A woman came under my observation in 1887. She was forty-three years of age, married, and had been for many years a patient of the physician whose case I have just related. She had for many years been subject to abdominal pain on the right side, which had always yielded to rest, diet, and opium. As she had always recovered after a short illness, she persistently refused operation. After she moved out of the city, I have ascertained that she had two attacks, between November, 1891, and February, 1892, and the last and fatal one during the summer of 1893. At the autopsy the appendix was found badly diseased and perforated, and the ovary and tube of the same side were also diseased. There were a ruptured abscess in the appendical region and many old adhesions throughout the whole peritoneal cavity.

Case III.—A woman, thirty years of age, married, no children, no uterine or pelvic disease, was suddenly attacked in 1888, after a heavy day's work, by abdominal pain, which was supposed to be simple colic. Home remedies were tried without relief, and I saw her in the morning. She had a temperature of 102.5° F.; pulse, 120; with marked tenderness over the abdomen and great distention. In the course of a few days, it was possible to make out a tumor in the right iliac region, but she was treated conservatively and finally recovered. In May, 1892, I saw her again.

---

[1] Read by invitation before the New York Medical Union, December 26, 1899

She had been under the treatment of another physician, who had diagnosed, first, peritonitis from a salpingitis, and then abscess about the rectum. When I examined her, I found a marked swelling in the right iliac fossa which could be readily felt bagging down into the rectum. The vesical symptoms were also well marked and urination was exceedingly painful. There was a well-marked induration in the vagina, and fluctuation could be made out between the rectum and vagina. As there was no time to lose on account of the patient's condition, operation was performed at once. An incision over the appendix evacuated an immense abscess. An opening was also made in the vagina, and both cavities were found in communication. Just at the end of the flow of pus from the vagina there was a gush of urine, and on injecting the bladder it became evident that there was an opening into that viscus. It was impossible to prolong the operation in order to find and repair the opening in the bladder. No examination of the urine was made before operating, because of the necessity of haste in our preparation. The patient made a complete recovery.

Case IV.—A man, fifty-five years of age, was attacked in 1889, at his country house, some miles from New York. I saw him the next day and made out a well-marked case of appendicitis. Operation was declined. On the twelfth day the abscess evacuated itself into the bowel, and the patient made a rapid recovery. Up to the time of his death from typhoid fever, three or four years later, he had no recurrence.

Case V.—In October, 1891, I saw a woman forty years of age, who declined to allow me to operate. In the past eight and a half years she has had but one recurrence, and that was six years ago.

Case VI.—In May, 1892, I saw a young man, twenty-four years of age, in consultation with Dr. Louis Morris, of New York. He was then recovering from a well-defined attack of appendicitis, and afterward had several attacks, but always recovered under conservative measures. Later, he had another attack and was operated upon by Dr. William T. Bull, in New York Hospital, for suppurative appendicitis. He recovered.

Case VII.—In April, 1892, a young man, aged twenty-six years, consulted me about a tumor in his abdomen. He gave the history of an attack of pain and tenderness in the right side, with fever, constipation, and vomiting about ten days before. He had been treated for intestinal obstruction, he claimed. A tumor, the size of an egg, in the right iliac fossa, painful on pressure, with considerable rigidity of the right side of the abdominal wall, was made out, and the diagnosis of appendicitis was easily reached. He declined operation and continued medicinal treatment, but never fully recovered. Constipation, with more or less pain, indigestion, and loss of flesh persisted, and he finally concluded, six months later, to be operated upon. An ulcerated and thickened appendix, much enlarged and in a very dangerous condition, was removed; he has had no discomfort since.

Case VIII.—In 1892, I saw a boy aged twelve years, who was brought to the hospital with a distinct attack of appendicitis. He improved so much within the next twelve hours, under the continued use of the ice coil and rectal enemata, that his friends declined to have him operated upon. In ten days he was discharged. About a year later, this boy had another attack, with suppuration, and was operated upon.

Case IX.—The next case was a young man aged nineteen years, who gave the history of constant indigestion. When I saw him, he had a well-marked attack of appendicitis, but was evidently improving. He was advised to have an interval operation, but claimed he was too busy to attend to it. He recovered, and resumed business, but had, within the next four or five months, several very mild attacks; finally, while away from the city, severe symptoms intervened, necessitating immediate operation, and death followed within a few hours.

Case X.—In March, 1893, a young man, twenty-five years of age, was attacked while visiting out of town. The attending physician made a diagnosis of renal colic, for which he was treated for several weeks. When I saw him, he had a large tumor in the right iliac fossa, peritonitis pretty well over the right side, pyrexia, and a pulse of high tension. Nevertheless, he was allowed to get out of bed, and was compelled to do so to attend to the calls of nature. As it was impossible to operate with any safety in the place where he was, he was treated conservatively and returned home some weeks later. About a year later, also while away from home, he had a second attack, from which he also recovered. He then remained well until November, 1898, when he had a third attack. I operated upon him, and found the appendix and surrounding tissues gangrenous, and he died of sepsis in a few days.

Case XI.—In March, 1894, I saw a young woman, about twenty-four years of age, in consultation with the late Dr. William H. Helm, of Sing Sing, N. Y. She had a tumor about the size of a small orange just above the appendical region. She was evidently over the severe part of her attack, and operation was advised against until all the acute symptoms had subsided. She has had no recurrence.

Case XII.—In December, 1895, I saw with Dr. Louis Morris a young woman, twenty-seven years of age, who had been seized with appendicitis on her way home from work a few days before. When I saw her, she had been steadily growing worse. Her home surroundings were distinctly unfavorable for any successful surgical interference, yet both she and her family absolutely declined to permit her removal to the hospital. There was a large, exquisitely tender induration filling the whole of the right iliac fossa, and her symptoms were extremely grave. I saw her several days in succession in connection with Dr. Morris, and there was but little improvement. The induration gradually extended upward toward the liver, and we expected her death at any time. Pleurisy, and then pneumonia, set in; finally she coughed up vast quantities of fecal-smelling pus, and the induration along the right side became distinctly less. She was then removed to a hospital, and was supposed to have phthisis, but finally recovered, and has had no further attacks.

Case XIII.—On December 20, 1896, a young woman, twenty-two years of age, walked into my office, complaining that for two days she had had pain in the right iliac fossa. She was in collapse, pupils widely dilated, marked diaphoresis, vomiting bile, tongue coated; pulse, 134; temperature, 99.8° F.; respiration, frequent and sighing. There was marked tenderness over the right iliac fossa, with spasm of the abdominal muscles and pain about McBurney's point. She was immediately sent home and stimulated all day, in the hope that her condition might improve enough to warrant surgical interference. The next day there was a discharge of pus from the rectum, and she gradually but slowly improved. For the next year she suffered more or less constantly with pain in the right side, but persistently refused operation. No severe attack has as yet appeared since the first.

Case XIV.—It was also in December, 1895, that Dr. Ellery Denison, of New York, asked me to see a boy of ten or eleven years of age, who had had a great deal of so-called colic. This had been going on for a year or more, and he complained, after each of these attacks, of pain and soreness, and walked with a limp. He refused to take part in any boys' sports, and was disinclined to undertake any exertion. At Thanksgiving time he had a more than usually severe attack, and Dr. Denison saw him. He found him with much tenderness on the right side, fever, vomiting, constipation, and distention. After a few days, a thickening was made out in the lower right side, and it was then that I saw him. An involvement of the appendix was evident. As he was almost over the attack, an interval operation seemed possible, and this was advised. A few weeks later, January 7, 1896, he had another attack, and operation became immediately advisable; a badly diseased and adherent appendix was removed.

Case XV.—On February 9, 1896, I was called by Dr. E. H. Bergen, of Princeton, N. J., to see a young man, aged twenty-three years, who gave the history of having had two or three attacks of pain in the appendical region, which had been treated by his family physician, and from which he had promptly recovered. The present attack had come on while he was at a ball a week or more before I saw him, and he had been treated conservatively from the first. Dr. Bergen was finally called in consultation and insisted upon my being sent for to operate. The abscess had ruptured into the general peritoneum before I reached the house, and in spite of early incision and careful lavage of the whole peritoneal cavity, he died fourteen hours later of general peritonitis.

Case XVI.—During the same year, one of my assistants at the New York Post-Graduate Hospital, while convalescing from an acute attack of articular rheumatism, was seized with appendicitis. I saw him at midnight, together with Dr. B. Farquhar Curtis. He recovered under anti-rheumatic remedies, but had another attack the following summer. He had another attack in 1898, but has not yet been operated upon.

Case XVII.—In April, 1896, I was consulted by a young woman from Sewickley, Pa., who gave the history of several attacks of severe abdominal pain during the four years of her college course. About a year before I saw her, she had a severe attack of peritonitis, and during the fall of 1895 she had had a severe illness that had been diagnosed as typhoid fever. It was during her convalescence from this last illness that she consulted me. She had constant pain in the right side, and frequently had a temperature as high as 101° F. The appendix could not be made out, but on palpation a tumor low down in the right side could be felt. After carefully trying treatment, the patient finally consented to operation, and the appendix was found to have sloughed off, and to be the centre of an abscess cavity, involving the right tube and ovary. She made a perfect recovery.

Case XVIII.—In July, 1896, I saw a patient who had been ill for several days with what was supposed to be inflammation of the bowels. He had general peritonitis, and his distention and tenderness were so great that it was impossible to make a satisfactory examination. A few days later, I could make out a distinct tumor in the right iliac fossa, both through the abdominal wall and through the rectum. Operation was advised, especially as he gave the history of several previous but mild attacks. An interval operation was decided upon. On his recovery, he was so impressed by the statements of the physicians who had treated him during his previous attacks, that he had only an inflammation of the bowels, brought on by indiscretions in eating, that he was inclined to doubt my diagnosis and thought I was riding a "fashionable surgical hobby." In February, 1897, I saw him again and examined him. He had had no discomfort since the summer, and the induration had practically disappeared from the region of the appendix. A few days later he went to his home in Rhode Island, and while there had a sharp attack with an abscess that finally ruptured into the bowel. He again recovered, and now believed his troubles were over and that his attacks had destroyed the appendix; but in the early part of this year he was taken with severe pain while on his way to business one morning, was removed from an elevated railroad station to Roosevelt Hospital, and operated upon at once for suppurative appendicitis, from which he made a slow recovery.

Case XIX.—During the summer of 1896, a medical student, who had been troubled with occasional attacks of indigestion, with abdominal pain, since childhood, was attacked in the night with diarrhœa and vomiting, pain and slight tenderness over the whole abdomen. There was also a slight rise of temperature. A few days' rest in bed with attention to the bowels relieved all the symptoms without arousing any suspicion of a distinct intra-peritoneal lesion. One day in August, he complained that all day he had had severe abdominal distress, but it was not marked enough to lead him to give up a bicycle trip. During the ride he was obliged to dismount several times because of abdominal pain, and finally he was compelled to give up the trip and return home by train. He suffered intensely during the journey back to town. By the time he reached home, his pain was intense; temperature, 100° F; and he was having diarrhœa and vomiting. I suspected appendicitis, but could not palpate the appendix. In a couple of days he seemed to be all right, and on the following Saturday went out of town to spend Sunday. While he was away, he ate very carelessly, and had another attack, which he attributed to his carelessness. He then remained unusually well, until a few days before Christmas, when he was taken ill again, and this time his appendix was palpable. Operation became necessary and considerable pus was evacuated. Two concretions were washed out, and during his convalescence two more escaped.

Case XX.—In October, 1896, I saw a young married woman, who gave the history of several attacks of peritonitis, dating back to childhood. She frequently suffered from attacks of pain in the right side, coming on usually in the night. There was some endometritis, and the right ovary seemed to be in Douglas' cul-de-sac, pushed down by a tumor on the right side. The left ovary could not be made out. On palpating the appendix, it was found pointing downward and very tender. She was much constipated and suffered constantly from intestinal indigestion. She absolutely declined operation at this time. About a year ago she had another very severe attack, and was several weeks recovering. She then decided to be operated upon. I found the appendix running downward, enlarged and thickened, and its apex entering into the tumor on the right side. This was found to be an abscess at the tip of the appendix, which was walled off from the general peritoneum by the right ovary and tube above, the uterus on the inside, and the left ovary, which had been drawn over, behind. Both ovaries and tubes were infiltrated with septic material, and it was necessary to remove them both with the appendix.

Case XXI.—During the same month I was consulted by a man from Honesville, Ky., who gave the history of three attacks of appendicitis. The first attack had occurred in the South. The physicians who had attended him in both these attacks advised against operation, and are probably carrying his name among their triumphs in curing appendicitis without the knife. A few weeks before coming to me, the third attack came on, and I saw him just after he was able to get about again. He had an ectopic testicle in the inguinal canal of the right side, and a hernia; but one could also palpate a tumor, which was exceedingly painful and about the size of an egg, in the lower right iliac region. While trying to make up his mind in regard to operation, he had a slight return of the pain, which settled the question. The incision was made so as to include the hernia, and so effect a radical cure at the same time. This hernia was found to be the caput coli, and an appendix fully six inches in length. The part included in the hernia was closely adherent to the intestine, but about two inches of the free extremity was movable in the abdominal cavity and was strangulated by the hernial ring. It was intensely congested and in spots almost gangrenous. Recovery was prompt.

Case XXII.—In December, 1896, in consultation with Dr. F. P. Williams, now of Kansas City, I saw a young woman, a cloak model, who had been attacked the day before, while at her business, with appendicitis. All the symptoms were well marked, and there was a very indefinite history of previous milder attacks of colic. She was admitted to my service at the Post-Graduate Hospital, but her mother, an ignorant woman, refused to allow her to be operated upon. She made a slow convalescence, and was discharged cured. About ten months later, she was suddenly attacked again and removed in an ambulance to a hospital, where an emergency operation was performed for suppurative appendicitis.

Case XXIII.—During the same month, I saw a young woman, a physician, who was attending the Post-Graduate Medical School. She had a well-marked attack, and operation was not undertaken because her parents refused their consent. She had several mild attacks during the winter, and was able to attend to her studies only very irregularly in consequence. This patient I have lost track of and cannot tell whether she was operated upon later or not.

Case XXIV.—A young man from Georgia was taken ill with appendicitis, while at a summer resort, and gradually recovered without operation. He came to see me on his way home, and I found a small tumor involving the appendix and advised him to have it operated upon at once. As he had already overstayed his vacation, he felt that he must first go home and arrange for the extra time, and he agreed to enter the hospital for operation at the end of two weeks. On his arrival at home, he had another acute attack, and as soon as he was well enough started for the train to come north. On the way to the station the appendix perforated, and he died of peritonitis.

Case XXV.—In November, 1898, I operated upon a man aged thirty years, who had an attack of appendicitis in Mexico, a few months before. Following that he had continued to have constant intestinal indigestion. As he was contemplating a trip of the same kind, he came to me. I found an enlarged appendix filled with large fecal concretions. He then made a complete recovery.

These twenty-five cases offer some suggestions in regard to what happens in the so-called conservative cases of appendicitis. I have frequently had physicians tell me that they cure their patients by one method or another, without operation. If it is not the rest and opium idea, it is the administration of salines, and then when the patient recovers from that attack, he is recorded as cured. Unfortunately, they do not go to the trouble, and it is a great deal of trouble, to trace these patients through the hands of the other medical men who treat them in their succeeding attacks, until they yield to the surgeon's knife, or find a final resting-place from the discomforts and torments of an ever-recurring intestinal lesion. Of the twenty-five cases, six (Cases I., II., IX., X., XV., and XXIV.) terminated fatally. This is a mortality of twenty-four per cent., and is rather startling when it is compared with the statistics of experienced operators. Three of these patients, it is true, were operated upon, but it was then too late to save them. One patient had perforation and was in collapse when I operated, one had gangrene of the appendix and of the surrounding parts and died of general sepsis, and the third was also operated upon after the abscess had ruptured and general peritonitis was well under way. All of these patients had several attacks, and could undoubtedly have been saved had they been operated upon earlier.

These statistics do not compare very favorably with the operative results. Taking my own simply as a basis for comparison, and including the two in this series that I operated upon *in extremis*, I have had one hundred and fifty-four cases with four deaths, a percentage of not quite 2.6.

Recurrences (I., II., III., V., VI., VIII., IX., X., XIV., XVI., XVII., XVIII., XIX., XX., XXI., XXII., XXIII., XXIV.): Only seven cases without history of recurrence! This is contrary to the usually accepted statements of the physicians who have reported that their cases of appendicitis always result in recovery under medical treatment. The explanation seems to me to be a comparatively simple one: They do not follow up their cases. Many of these patients I have traced from one physician to another before their histories were complete. The physician sees a patient in one attack and he gets well after a certain time. He wanders away from the town, or, finding that he is having more or less trouble in the way of indigestion, constipation, and so forth, he consults some one else, who sees him in his second attack, and so on to the end of the chapter.

There is nothing especially instructive about the recurrences, except the gradual tendency to increase in frequency and in severity. I do not mean by that that every attack is worse than the last, but that the general condition gets worse, and the sum total of the attacks one year is apt to be greater than that of the year before. Nor do I mean to be understood as claiming that the attacks need necessarily follow one another in rapid sequence. On the contrary, several months or even several years may elapse between the attacks, but in the end the testimony of the patient will be that the colic is more frequent and more severe, the constipation less readily combated, and the indigestion more constant and more marked. The right spasm is more distinct and more tense; the patient is inclined to protect the right side and keeps it turned away from danger as much as possible; the appendix becomes more readily palpable and more painful to the touch. Flesh is gradually lost, and the general tone is decidedly below the proper and usual standard.

Operation.—This was ultimately performed in fifteen of the cases, and three of them ended fatally. Two of these have already been mentioned in speaking of the deaths. The other one was also operated upon when it was too late, general peritonitis having already supervened. Of the remainder, ten patients developed pus, and had to have the abscess opened; one had the appendix included in a hernia with strangulation of part of the appendix, and one had a constant intestinal discomfort that led him to have the operation performed, and his appendix was found overdistended with large fecal concretions. Some of these patients could possibly have continued longer without operation, but every one of them must have had a tedious recovery, with the usual slow absorption of the pus, or its escape into some of the hollow viscera, or gradual working through the abdominal wall, or it would have ruptured into the general peritoneum, and death would have promptly followed as in the three patients who did die.

No Operation.—There were ten cases not operated upon. Three of these patients died, one of perforation of the appendix by fecal concretions and general septic peritonitis, one of general sepsis and peritonitis from the rupture of an appendical-ovarian abscess, and one of general peritonitis from perforation. Every one of these might have been saved by early operation, and every one had given abundant symptoms to permit a proper diagnosis to be made.

Seven patients recovered without operation; one was lost sight of completely, and I suppose should not appear in this group of cases that I have attempted to trace from their first to their last attacks of appendicitis. One (Case V.) had her first attack in 1891 and her second in 1893, and has been free since.

Two (IV. and XIII.) had abscesses that ruptured into the bowel, and one had no recurrence up to the time, three years later, when he died of typhoid fever. The other remains well (three years). I cannot help calling attention, however, to the fact that it is not always safe to assure the patient that he will be well after the rupture of an appendical abscess into the gut. Case XVIII. illustrates that fact very forcibly. This man recovered from his first attack and then declined an interval operation. Seven months later he had another attack while out in the country, and the physician who treated him assured him, when the abscess ruptured into the bowel, that he was safe from future attacks. In about nine or ten months, however, he had another attack and had to be operated upon.

One patient (XI.) has never had a recurrence. One (XVI.) has had a number, the last during last spring, but as he has a marked rheumatic diathesis and the attacks have yielded to anti-rheumatic treatment, he continues to decline to be operated upon. He is, therefore, still under observation. One other patient (XXIII.) was a young woman, a physician, who continues to have several attacks each year, and who is now practically invalided by the condition, yet her parents decline to give their consent to operation. The last patient (XII.) had an immense abscess, that gradually burrowed upward, finally penetrating the pleura and discharging through the lung. But she has now been perfectly well for over a year.

On April 16, 1896, I read a paper before the Medical Association of Georgia, which has never been published except in the transactions of that society. As a basis for that paper, I took five hundred and fifty-eight cases from literature and tabulated them. Four hundred and forty-five resulted in abscess, perforation, peritonitis, and so forth.

The following table was made up at this time:

Perforation without given cause	11
" with abscess	10
" " ulceration	16
" " peritonitis	32
" " concretion or foreign body	41
" " gangrene	7
" " gangrene and concretion	19
" " inflammation	13
" " hardened fæces	1
" " concretion and peritonitis	24
" " foreign body and peritonitis	7
	181
Abscess without perforation, uncomplicated	136

Gangrene	9
Gangrene with concretion	2
Inflammation with concretion	3
	86
Genera lperitonitis with concretion	5
" " " foreign body and gangrene	1
" " " foreign body	3
" " " ulceration	1
	10
Total number of cases	437

This collection of cases, taken at random from the literature of the disease, illustrates the futility of medical treatment in the vast majority of the cases, and bears out most emphatically the conclusions arrived at by most surgeons as a result of clinical experience.

Symptoms following an Acute Attack.—Constipation and intestinal indigestion are by far the most constant symptoms. These are accompanied by a great deal of flatulence, by colicky pains in the abdomen, sometimes of considerable intensity and sometimes referable to the appendical region, though more often near or immediately under the umbilicus.

The tongue is usually badly coated, especially toward the back, and the breath is foul. Often eating increases the discomfort, and occasionally the flatus interferes with respiration by pressing on the diaphragm. On examination of the abdomen, tenderness is nearly always elicited by pressure upon the appendix, and that organ is nearly always palpable.

In one patient, the acute symptoms were mistaken for renal colic, and he suffered constantly from indigestion. When he was dying and having fecal vomiting, he said, "That is the stuff I have been tasting all the time during the past year."

One need not go further, it seems to me, than the study of a few series of cases similar to these, to reach a conclusion that an attack of appendicitis predisposes the patient to a recurrence, and it is also conclusively shown, I think, in this *résumé* of my own cases, or rather cases I have been in a position to follow up, that operation offers the best, the safest, and the shortest method of treating the condition.

24 West Fiftieth Street.

HOW THE MILK SUPPLY OF NEW YORK MAY BE IMPROVED.

By HENRY DWIGHT CHAPIN, M.D.,

NEW YORK.

No subject of greater interest than the production and care of cows' milk can come before those who are interested in the public health. Its importance in large communities, where the difficulties of delivery and proper preservation are great, warrants much more attention than is generally bestowed upon the problem. The magnitude of the whole question can be appreciated when it is known that 1,250,000 quarts of milk are daily delivered into New York City, and that this amount comes from five States, including thirty-four counties, and some of it from a distance of five hundred miles. The city itself, however, is no small dairy ground, as 23,500 cows are contained within the municipal limits, which furnish a certain amount of milk for the inhabitants. The writer's attention was first drawn to this question in studying the home modification of cows' milk for infant feeding. The condition and ingredients of the milk in any given locality assume a great importance when this problem is approached. Hence an effort has been made to learn something of the actual conditions of the milk trade in Greater New York.

There are in the boroughs of Manhattan, Bronx, and Brooklyn over fifty wholesale and retail milk dealers, whose capital ratings, according to the commercial agencies, range from $3,000 to $1,000,000. A list of questions was sent to these dealers asking, among other things, whether they sold bottled milk to families; where the milk is bottled, in city or country; what percentage of butter fat their milk is guaranteed to contain; whether the milk runs uniform in quantity of butter fat; if there is any variation in quantity of butter fat; in what months of the year is there the least quantity, and in what months the greatest quantity; is the milk run through a centrifugal machine to remove dirt; how soon after milking is the milk delivered in the territory covered; what territory is covered; is the tuberculin test ever applied to the cows?

Nineteen replies were received, all from large dealers, their combined capital ratings being about two-thirds of the entire capital invested in the milk business in these boroughs. These dealers all furnish bottled milk, which they guaranteed to run four per cent. fat and over, the least amount of fat being found in the spring months. Three of the dealers use separators to cleanse their milk, the others simply claiming especial care in the matter of cleanliness. The time of delivery is from twelve to thirty-six hours after milking. Nine out of the nineteen dealers say the tuberculin test has been applied to their herds, although not regularly. Three simply stated that there was oversight of the herd by a veterinarian. A few of these dealers owned the cows producing the milk, but the great quantity of milk is collected by companies who have depots in various dairy districts and who buy from farmers and dairies. These companies have regular forms of contracts, which are generally based on the "Fifty Dairy Rules" of the United States Department of Agriculture. These contracts may allow the companies' inspectors to examine the cows, stables, and utensils, regulate the manner of feeding, handling of milk, etc., and sometimes even provide for notice to the company of any contagious disease in the family or help of the producer. The milk is brought to the depot at stated hours, cleaned if necessary, and immediately bottled or canned, and shipped either in boxes containing ice or in refrigerator cars, and delivered within twenty-four to thirty-six hours after milking. About seventy-five per cent. of the milk now received in this city comes from these receiving stations, or, as they are usually called, creameries.

There is no doubt that milk handled in this large way is an improvement over the old plan of the various milk dealers receiving their supplies from numerous small, independent dairies. A system of judicious control and oversight is likewise simplified. In order to learn the actual amount of butter fat contained in the milk supplied by our best dealers, thirty-two assays were made during the past fall and winter months of the milk purchased from these dealers in the open market. These assays showed the lowest proportion of butter fat to be 3.10 per cent., and the highest 5.25 per cent. Twenty-two of the assays showed four per cent. and over, and the other ten showed very close to four per cent., such as 3.52 and 3.66 per cent. From this it seems fair to conclude that milk containing four per cent. of butter fat is a good average as supplied by first-class dealers in this city.

When it came to cleanliness, the showing was not so good. A large number of the bottles exhibited particles of dirt in the bottom. It is a very difficult matter to keep milk from contamination, especially when handled in very large quantities. Much of this dirt is doubtless innocuous, except that early souring of the milk is induced. The prevention of any contamination of milk, as handled at present, is a subject for careful study and observation. In order to learn what impurities get into milk, a visit was made to a receiving station in the country where eighteen hundred quarts of milk were run through a separator, consuming a little over two hours. The layer of foreign matter was then scraped from the sides of the bowl, and found to contain air, pus, blood, mucus, fibrin, great numbers of bacilli and cocci, and detritus from vegetable matter, probably from fæces. It seems that with extra care at the source of the milk supply, these impurities, even in small quantity, could be kept out of the milk. If the milk is drawn from healthy cows that are kept clean and in hygienic surroundings, by healthy milkers who keep scrupulously clean, and is received into absolutely clean vessels, and is then strained, aerated, and kept cool until delivered, the question of a proper milk supply for any locality thus served will be solved. The real key to the situation is the handling of milk on the farm, far away from the inspectors of the health department. All the latter can do is to see that the milk has not spoiled upon being delivered, that it does not run below three per cent. butter fat, and that no preservatives have been added.

In spite of the vigilance of the health inspectors, there is a large sale of various preservative solutions that are presumably used for the purposes for which they are sold. Dairy supply firms openly advertise the sale of these preparations. Their commonest active ingredients are boric acid and its sodium salt borax, and formaldehyde. While small amounts of these substances may not always in themselves be directly injurious, they have a tendency to harden the clot of casein and thus make the milk less digestible.[1] Anything that aims to take the place of strict cleanliness in the handling of milk is reprehensible, as by masking the effects of uncleanliness less care is naturally taken, and various impurities will not be suspected because their usual effects are not observed.

The great need of a city like New York is a strictly clean milk that will require neither superheating nor the addition of any preservative in order to keep it in safe condition against the time of consumption. Such milk should be available to every one at a fair price. Considering the importance of milk in the nourishment of infants and as the universal food, the subjects of its source, care, and distribution are properly a matter for consideration by the medical profession. The writer believes that doctors have it in their power to accomplish much toward settling this question on a more satisfactory basis than it now exists. It might take the form of a medical commission which would make a careful study of the whole subject, and then enter into friendly and advisory relations with any milk dealers who would desire the benefit of their counsel. If a few dealers take hold of this subject and furnish an extra clean and fresh supply of milk, collected and distributed under the strictest precautions, physicians should know and approve of it. Self-interest will compel other dealers to follow, and in time an abundant supply of the best milk will be obtainable by all, rich and poor alike, the demand for milk will increase, and the dealers will be thus rewarded for any bettering of their supply. The idea of a commission of physicians becoming an advisory committee in the production and handling of milk was started some years ago by Dr. Coit, of Newark, and has since been in successful operation with one of the local dairymen. It is also carried out in New York, Buffalo, and various other cities. If this system can be made to work with one dealer, why cannot it be enlarged to take in any dairyman or dealer who wishes to take advantage of its provisions? It is in some such way that the general supply of a large city can be gradually but appreciably improved.

If physicians and dairymen will thus meet in earnest council, we may gradually get what both should desire—a strictly clean milk that runs fairly uniform in its ingredients.

Salophen is prefered to salol by Caspar in typhoid fever. It acts as an antifermentative in the intestinal canal.—*Medical Examiner.*

---

[1] "Lactoform consists essentially of casein precipitated by metallic salts and subsequently hardened by formaldehyde. It is employed in place of horn, ivory, ebony," etc.—"Dairy Chemistry," by Henry Droop Richmond. London: Charles Griffen & Co., 1899.

A NEW "T" BANDAGE.

By W. O. GREEN, M.D.,

CLINICAL LECTURER ON RECTAL DISEASES AT THE KENTUCKY SCHOOL OF MEDICINE, LOUISVILLE, KY.

For the past three or four years, in private and hospital practice and at his clinic, the author has employed a simple device for holding dressings in place about the anal region. This is known in the hospitals and infirmaries of this city—after his name—as the "Green T bandage."

It was devised first for convenience and to save time in the infirmaries, and, later, in private practice as a substitute for the various awkward contrivances made by patients or inexperienced attendants, who failed to get an adequate idea of the instructions given, or who had a preconceived notion of the "proper" manner of making a "binder."

It was devised also because in some points it seems to offer an improvement upon the regular form of T bandage, which has made it very useful to the writer and which would appear to justify its more extended use.

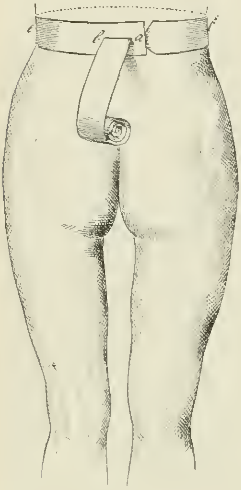

Fig. 1.

The "Green T bandage" is quickly made and requires no sewing, buttons, or pins. It is made of a single piece, and can be more quickly loosened or tied if the knot is properly placed than the other forms of bandage of this type. When the material is of the proper thickness and breadth it conforms nicely to the parts and holds the dressings in place satisfactorily.

Sometimes it is found that after a T bandage is applied the waistband will be found too loose or too tight, which will necessitate a removal of the pins to readjust this portion of the bandage. It may happen that when this change is made by the patient, the dressings become disarranged and fall down, and require the assistance of the surgeon or nurse to be satisfactorily replaced. The patient may readjust the bandage under consideration by untying and relaxing or tightening the perineal strip with one hand, while the other hand is held against the dressings to allow the perineal strip to slide smoothly over their surface.

One knot only is required, and this should be made in front. Should the knot be placed at the back, when the patient assumes the recumbent posture it becomes exceedingly uncomfortable, and the same may be said of a button and sometimes of a large-sized safety-pin in this locality. In the ordinary improvised T bandage, made from a roller, it is not uncommon to see one or two knots in the back. The discomfort which follows naturally will cause the patient to attempt to readjust the bandage, which, in turn, will likely be followed by a misplaced and uncomfortable dressing about the perineal region.

It is customary in many infirmaries to keep a stock of T bandages, which have been carefully made and are intended for prolonged service. When one of these bandages has been removed from a wound, if not too much soiled, it is separated from the other dressings, washed, and laid aside for another fresh dressing. The simplicity and cheapness of the bandage under consideration offer little temptation for washing and a second application. In consequence, especially in those cases in which he desires most careful aseptic methods, the surgeon may feel less apprehensive that other than a new and clean bandage will replace the one which has been soiled and removed.

This bandage is always the proper length because it is not made until applied, when there is sufficient material provided for several bandages from the same piece. Narrow or broad strips made of this material, by movement of the muscles about the parts, are apt, in the course of a few hours, to cause the abdominal band to roll into a sort of string and become very uncomfortable to the patient. For this reason it is necessary to employ heavy, thick material. The material best adapted to the purpose is the heaviest unbleached cotton made in strips not less than four inches wide. The average length of each bandage is two yards. It has therefore been found convenient to have the material made into rollers six yards long, which will ordinarily be sufficient for three bandages. Rollers longer than this are undesirable, because of the necessary length of the cut in the back, through which the perineal strip passes from the waistband.

In preparing the bandage for application, about six inches of its length is unrolled and folded upon itself at a point about three inches from the end. In the centre of the presenting fold a cut is made with a pair of scissors. In consequence of the fold the cut should be made only one-half the desired length when unfolded, and the limit of the cut at the outer point should be at least an inch or an inch and a half from the free end of the bandage. This will be about half an inch or more than the diameter of the roller.

The following diagrammatic cuts are intended to simplify the description:

Fig. 1 represents the waistband applied with the perineal band brought through the cut *a b* (mentioned above) placed in the centre of the back. In order to make the bandage comfortable, it is necessary to have the bands laid flat against the surface of the body, thus avoiding folding or rolling into a sort of string. Should the patient apply the bandage, the roller should be passed through the cut (*a b*) in front, after which it can be slipped around to the centre of the back, preparatory to making the perineal band. It will be seen from this arrangement how pins, buttons, or knots may be omitted from the point of attachment in the back, and at the same time the perfect ease with which the perineal band and waistband can be made to conform to the parts. The broken line *e f* is intended to indicate the course of the bandage across the front of the abdomen.

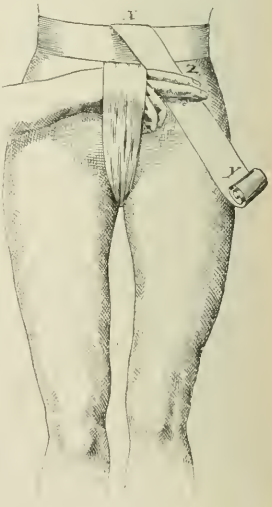

Fig. 2.

Fig. 2 gives a front view of the perineal strip continued up and passed under the waistband. This figure also represents the first stage of the knot, which is a very important part of the bandage. It is important, while tying, that sufficient tension be made to hold the dressings in place. It is equally important, while tying, that nothing shall slip, and that when it is necessary to remove the bandage no trouble shall be encountered in untying. The method which is here illustrated will fulfil these requirements, and the knot—which is a re-enforced bow-knot—may be made in less than five seconds with only moderate dexterity.

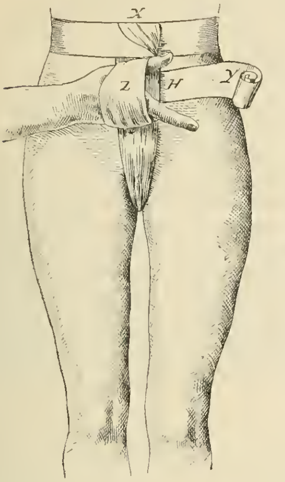

Fig. 3.

After bringing the perineal band above the waistband at the point *X* (same figure) about eighteen inches of the free end is unrolled, which is brought down and held firmly to the side, *Y*. The other hand is passed under the perineal band and the strip *X Y* caught near the waistband, *Z*, and drawn back in a loop, making the tension from *Z* to *X*.

Fig. 3 shows the loop slipped across the knuckles, which is drawn across the front of the perineal band. The index finger catches the remainder of the strip *H Y*, the end of which has been brought up parallel with the waistband, while the thumb maintains the tension from above.

A second loop is made by drawing the band *H Y* through at *Z*, and the knot is completed as represented in Fig. 4. The roller is cut off after the knot is tied. The time required for making and applying should not be more than two or three minutes, even by one who is awkward.

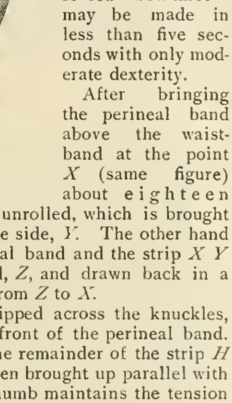

Fig. 4.

Thus far the bandage has been employed almost exclusively for holding in place rectal dressings, but it can be used with equal efficacy for genito-urinary and other perineal dressings. For the first dressing subsequent to rectal operations the writer does not employ this bandage, because sufficient pressure cannot be brought to bear to give firm support to the anal region to prevent straining, and control, to a greater or less extent, the capillary and venous bleeding. A special form of perineal bandage is employed for this purpose.

709 Second Street.

Smallpox prevails to a large extent throughout the South and West due, it is claimed to culpable negligence in enforcing vaccination.

The Hæmostatic Use of Gelatin.—It is perhaps too early as yet to fix a final estimate of the value of gelatin in stopping hemorrhage. In cases which resist other methods of treatment, it offers some hope—hæmophilia, inoperable aneurisms, etc.—J. B. Nichols, *Medical News*, December 2d.

Polyarthritis Deformans in Childhood.—M. Moncorvo reports a case in a child aged five and a half months, which evidently began at the end of the second month of life. About forty-nine cases are on record as occurring between the ages of three months and fourteen years. The author believes that the microbe theory in relation to articular rheumatism is probably correct. A few bacilli similar to the bipolar bacillus of Bannatyne and Walman were found in a few drops of blood taken near an affected joint in his little patient.—*Bulletin de l'Académie de Médecine*, January 9, 1900.

The Staining of Gonococci with Neutral Red, in Living Leucocytes.—Plato (*Berliner klinische Wochenschrift*, December 4, 1899, p. 1085) reports the results of observations with regard to the tingibility of gonococci in the leucocytes of gonorrhœal pus. He found that if a small drop of fresh gonorrhœal pus be admixed with a platinum loopful of a dilute solution of neutral red in physiological salt solution (1 c.c. of a cold saturated aqueous solution of neutral red and 100 c.c. of physiological salt solution) and the mixture be examined in hanging drop or in the wet state, a number of the intracellular gonococci will be seen to be stained deeply red, in many instances without any other portion of the cells being stained. At times, in cells with and without gonococci, bright red granules are visible that will not cause confusion. The specific granulations at times stain light yellow, but the nuclei in general remain unstained. Not all intracellular gonococci are stained, but stained and unstained may lie side by side. If the leucocytes are stimulated to amœboid activity by gently warming the slide, gonococci that were at first stained in the granular portion of the protoplasm will at times gradually lose their color if in consequence of the movement of the cell they become displaced into the homogeneous marginal zone of the leucocyte, and they become again stained when they are subsequently resurrounded by the granular protoplasm. The conclusion that only degenerating or degenerated intracellular gonococci accept the stain appears unjustified in view of this fact. Division or spontaneous movement of intracellular stained gonococci cannot be observed. Leucocytes that contain only a small number of gonococci are at times characterized by especially active amœboid movement, while pus corpuscles filled with gonococci as a rule exhibit no manifestation of vitality and are provided with a more or less deeply stained nucleus. Although numerous other intracellular micro-organisms, also resembling gonococci, were examined according to the method described, in no instance were similar rapidity and intensity of staining observed, so that possibly neutral red may be considered an aid in the differentiation of the gonococcus from similar micro-organisms. Extracellular gonococci, as well as other micro-organisms, cannot be stained in hanging drop in a solution of neutral red of the concentration stated, even after exposure for days. In fixed preparations more concentrated solutions of neutral red (20 c.c. of a cold saturated solution of neutral red to 100 c.c. of water) stain both the extracellular and the intracellular gonococci a deep red within a few seconds, and the nuclei invariably less intensely, so that optic concealment of the gonococcus by the nucleus does not take place.

MEDICAL RECORD:

WM WOOD & CO, 51 Fifth Avenue

New York, February 10, 1900.

PRECAUTIONS AGAINST THE PLAGUE.

If it were not for wars and rumors of war, which almost monopolize public attention, the spread of the plague to all quarters of the globe would give rise to much more alarm and discussion than are at present the case. The sinister fact, that the disease has for the first time gained a footing in the western hemisphere, does not appear to be regarded as an event of vital importance, and although the occurrence of plague on a vessel in New York harbor created a temporary sensation of dread, this feeling was quickly lulled into one of security, based chiefly on the widespread opinion that it is virtually impossible for the malady to make headway in places where a proper system of sanitation is carried out.

These optimistic views are certainly to a large extent justified by the history of the course of the plague in other parts of the world. Within recent times proof has constantly been afforded that plague rages most virulently among dirty surroundings, and many experts hold that where the environment is cleanly its ravages are easily controlled. However, this latter contention is thought by others to be more or less open to doubt, as there are several instances on record in which the disease has made decided progress under conditions presumably unfavorable to its spread. On more than one occasion after it has been proudly proclaimed that in a certain city or town the plague has been wiped out by the energy displayed in rendering the sanitary system complete, the news has come that a recrudescence has occurred on a larger scale than before. Nevertheless, in the light of experience during the past decade it may be said that efficient sanitation is the best safeguard against plague. In localities where hygienic arrangements are good the bacilli of the disease will find no soil suitable for its incubation and propagation. Again, our knowledge as to the best means of treating the disease has advanced, albeit but slowly. No absolutely reliable specific has yet been discovered, but investigation has demonstrated its cause, and it has been also shown that when possible isolation of patients and segregation of those exposed to infection are among the most prominent factors in limiting the spread of plague. Consequently the enforcement of these measures, a rigid adherence to the laws of sanitation, together with the prophylactic and curative methods now at hand, would seem to provide sufficiently strong barriers against the plague securing any but a temporary foothold in this country.

There is unfortunately a dark side to the question. The plague has not only planted itself in Brazil but is gradually drawing into its net all the islands of the Pacific, and from these, and especially from the Hawaiian islands, comes the greatest danger of importation into the United States. The disease promises to spread like wildfire among the inhabitants of this group, while our traffic to and from Honolulu is considerable and frequent. The conditions prevailing in many of the American towns on the Pacific coast are not such as to warrant the belief that, if the plague were to obtain an entrance, its extermination would be a matter of little difficulty. There is a large Chinese population, and this race is peculiarly predisposed to plague infection. In addition the climate, overcrowding, and uncleanly habits of the aliens in that part of the United States favor diseases of this description.

The various ways in which plague can be transmitted have already been fully dealt with in former numbers of the MEDICAL RECORD, so that it will suffice to consider the measures in force to prevent its ingress into the United States. The maritime quarantine regulations contained provisions relating to the plague, but the Treasury Department has deemed it expedient under the exceptional circumstances to supplement these with special regulations, which order that at foreign ports and places infected or suspected of being infected with plague the United States quarantine regulations referring to cholera shall be observed with regard to vessels and cargoes bound to the United States. Quarantine regulations relating to cholera are also to be observed at ports and on the frontiers of the United States. Dr. Wyman, the surgeon-general, Marine-Hospital service, in a pamphlet recently published by him, speaks thus of the quarantine equipment of this country: "The government is well equipped with quarantine stations for the disinfection of infected vessels, and has besides several large stations where immigrants can be detained in barracks under observation." Dr. Wyman goes on to say: "It seems impossible that the plague should ever again ravage the earth as in previous centuries. Modern quarantine is effective to a degree. Though old-fashioned and absurd as administered by some of the European countries, and imperfectly executed in others, it nevertheless has proven and will continue to prove a powerful shield against this Asiatic invasion." The following suggestions with respect to public hygiene are advanced by Dr. Wyman: "The destruction of rats and other rodent animals; the prevention of congregations of individuals, as fairs, celebrations, and pilgrimages; the surveillance and supervision of markets; the cleanliness of the soil; the regular removal of garbage; the cleanliness of habitations; the particular supervision of places, workshops, forges, etc., intended for occupancy by the laboring and industrial classes; the cleaning and regular disinfection of latrines and cesspools; the care and cleaning of gutters, etc. Administrative care should also be brought to bear to improve the sanitary condition of notoriously unsanitary quarters and dwellings."

The primary and principal object in the fight against the plague is to keep the disease out of the country, and this, according to the views of the most distinguished authorities, can be effected only by a strictly rigorous system of maritime quarantine. Our system is undoubtedly a good one, but, if it requires strengthening, nothing should be allowed to stand in the way of legislation tending to the preservation of the health of the country at large. The next and scarcely less important aim is to have our towns in so efficient a state of sanitation that if the disease were to gain an entrance it would be given no opportunity to spread. In this respect many of our seaboard centres of population will be found wanting. Therefore it would be well if the advice proffered by Dr. Wyman regarding public hygiene was taken to heart and promptly acted upon by the city fathers throughout the land.

OSTEOPATHY IN NEW YORK.

THE medical profession, in this and other States, has none too easy a time in combating fraud and charlatanism on one hand, and ignorance and stupidity on the other, and the development of something new under these headings, called osteopathy, has added a fresh source of difficulty and injustice. The supreme court of New York, in Smith *vs.* Lane, 24 Hun, 632, has decided that a man who practises massage does not practise medicine, and prosecutions of osteopaths have therefore been discouraged on the assumption that osteopathy is massage.

We cannot see the justice or the force of this form of argument. An osteopath pretends to diagnosticate and treat by manual means many forms of disease, and does not limit himself to working under the direction of some one else, as is almost invariably the case with the masseur. When the physician wishes a patient to have massage, he prescribes it as he would any other form of treatment, and it is given by an individual trained for such work, the physician still being responsible for the welfare of the patient. When the osteopath finds a victim, he makes his own diagnosis, decides on and carries out his own treatment, and is apparently neither legally nor morally responsible in any way for the outcome of his ministrations. We cannot see how the mere fact that the osteopath does not order any drugs for his victim should relieve him of the responsibility of practising or attempting to practise medicine. Does the surgeon who straps a sprained ankle or a fractured rib practise a branch of medical science, or would the law relieve him of responsibility in case of a bad result from such conditions, if he should plead that he had used no internal medication, and was, therefore, not practising medicine? The answer does not require argument. The important fact is that the osteopath presumes to make a diagnosis, and to institute what he dares say is proper treatment, and this ought to render him liable to prosecution under the medical law, without considering the fact of subsidiary importance that no drug has been actually given.

If the osteopath cannot be reached under the present medical law, there ought to be an amendment, for if something is not done the regular practitioner will actually have less protection than the impudent charlatan. If a registered physician can be proved before a jury to have been negligent, the complainant can recover heavy damages, but it is very doubtful whether the unregistered and unqualified osteopath could be reached in this way. It would be an excellent thing if the County Medical Society could find out whether, in the eyes of the law, it is not the making of a diagnosis and prescribing of treatment which constitutes practising medicine, and not merely the application of treatment, with a difference between treatment with or without internal medication. We should certainly try to be sure that any person who pretends to treat or prescribe for the sick or injured in any way, on his own responsibility and initiative, should be compelled to come up to a certain standard of proficiency in such subjects as anatomy, physiology, and obstetrics, be his system of therapeutics what he likes, and we should be prompt to deny that the osteopath is not attempting to practise medicine, merely because he does not prescribe drugs.

RECIPROCITY IN MEDICAL LICENSING.

A MOVEMENT has been set on foot in at least one State of this country with the view of abolishing the present anomalous, not to say absurd, conditions ruling the laws of medical practice. As mentioned in the MEDICAL RECORD of October 14th, the Wayne County (Mich.) Medical Society has despatched circulars to the authorities of the different States and Territories requesting their opinions as to the best steps to be taken which, in time, may lead to a uniformity in the requirements for the license of practising medicine in the United States. The State board of medical examiners of New Jersey, in their report for last year, express their desire to recognize and indorse the medical licenses issued by other State boards as far as their academic and medical standards will admit. Several other State boards would doubtless be willing to go as far as the New Jersey board, but it is certain that until the standard of medical education shall be placed on a uniform basis in all the States, the existing deadlock, so far as interstate reciprocity of medical license is concerned, must continue.

It is nevertheless a happy augury for the future that even the "thin end of the wedge" has been inserted, and if the members of the medical profession will band themselves together and will use their utmost endeavors to bring medical education in all the States and Territories upon the same plane, the time cannot be far distant when matters will be upon such a footing that interstate reciprocity of medical licensing will at any rate be brought within the range of practical politics. The question will be considered in all its bearings by the National Confederation of State Examining and Licensing Boards at their meeting at Atlantic City in

June next. This confederation, being composed of representatives of the examining-boards of the different States, can alone solve the problem. Their agreement upon a minimum academic and medical standard would bring about the desired result. Efforts should be made, and these quickly, to remedy the prevailing incongruous state of affairs. First establish a uniform standard of medical education, and then will follow, "as the night the day," interstate reciprocity in medical licensing.

NURSING IN THE BRITISH ARMY IN SOUTH AFRICA.

Male nurses are rarely met with in Great Britain. All the nursing at the large hospitals in Great Britain is done by women. The British Medical Hospital at Netley is probably the only large institution of its kind in the United Kingdom where the nursing-service is performed by men. In times of peace this system works smoothly enough, and women on the whole are found to do the duties required of them as efficiently as men. But war places a different aspect on the matter, especially in a campaign on so large a scale as that now being carried on in South Africa. The edict has gone forth from the War Office in London that women nurses shall not be allowed to serve in the field hospitals, but must be retained at the base hospitals. In consequence of this order, and owing to the fact before mentioned, that there are but few trained male nurses in Great Britain, there is said to be a deplorable scarcity of these necessary adjuncts to the surgeon at the front. Of course the regular army has with its medical corps orderlies who are trained in and fulfil the duties of nurses, but when it is considered that the army medical corps is far below its proper strength, there will be no difficulty in comprehending that its trained nursing-staff is not numerically so efficient as it should be.

Notwithstanding this reported state of affairs, the New York *Herald*, in its Sunday edition, quoting from a private letter from Sir William MacCormac, says that there is much ill-feeling between the army medical officers in South Africa and the female nurses at the base hospitals, some of the former urging the sole employment of male orderlies. The thought will naturally strike one that the services of a well-trained female nurse must be preferable to those of a half-trained male nurse. It is satisfactory to note, however, that on the whole the much-decried medical army corps in South Africa has up to the present come out of their trying ordeal with flying colors. This indeed is the one bright spot in the dark cloud of disasters which have overtaken the British arms in that country.

The Study of Cancer.—The Massachusetts State board has undertaken a collective investigation of carcinoma, with a view to secure more accurate information regarding certain disputed points, especially the alleged increase and the infectiousness of the disease.

News of the Week.

Sir Thomas Grainger Stewart, of Edinburgh, physician in ordinary to the Queen in Scotland, died on February 2d, at the age of sixty-three years. He was graduated in medicine from the University of Edinburgh, and after graduating studied in Berlin, Prague, and Vienna. On his return to Edinburgh he became resident physician in the Royal Infirmary. In 1876 he was appointed professor of medicine and clinical medicine at the University of Edinburgh, and held this chair at the time of his death. He was at various times president of the Royal College of Physicians in Edinburgh, of the Medico-Chirurgical Society of Edinburgh, and of the British Medical Association. He was knighted in 1894. He was a writer and teacher of note, the diseases of the respiratory organs and of the kidneys being his favorite objects of study. Among the best known of his works were a treatise on Bright's disease and the article on diseases of the trachea and bronchial tubes in the "Twentieth Century Practice of Medicine." He was a member, active and honorary, of many societies, among them the College of Physicians of Philadelphia.

Typhoid Fever in Army Camps.—Dr. Victor C. Vaughan, of Ann Arbor, who was commissioned by the government to investigate the causes of typhoid fever which prevailed to such a frightful extent among the troops during the Spanish war, has sent his report to Washington. In this report, according to a synopsis published in *The Sun*, he says camp polluting was the greatest sanitary sin committed by the troops. His conclusions are that about one-fifth of the soldiers developed typhoid fever, and army surgeons correctly diagnosed fewer than one-half the cases; that the percentage of deaths from typhoid fever was 7.5; that about eighty per cent. of the total deaths were due to this disease, but that the percentage of deaths from typhoid fever is not so high "if we accept the diagnoses given in the official reports." He blames the superior line officers for locating camps in the face of the protests of medical officers.

The Antivivisection Bill.—Some changes have been made in the constitution of the Senate committee on the District of Columbia, upon whose action depends the fate of Senator Gallinger's antivivisection bill. The committee now consists of Senator James McMillan, Michigan, chairman, and Senators J. H. Gallinger, New Hampshire; H. C. Hansbrough, North Dakota; R. Redfield Proctor, Vermont; J. C. Pritchard, North Carolina; Lucien Baker, Kansas; George L. Wellington, Maryland; S. R. Mallory, Florida; W. V. Sullivan, Mississippi; W. A. Clark, Montana; Thomas S. Martin, Virginia: William M. Stewart, Nevada; and Richard Kenney, Delaware. Personal letters may be addressed to them or to other senators. Petitions should be addressed to the Senate of the United States.

Carbolic Acid is, we are informed, to become more expensive. If those who have the price regulation in charge are acting in the interest of humanity, and have taken this means to diminish poisoning accidents and the use of the drug for suicidal purposes, they deserve all praise. The MEDICAL RECORD has attempted to point out to those who would reach other worlds by the poison route, that there were other and better and less painfully distressing drugs which could be employed; cheapness, ignorance, and ease of obtaining, have been the reasons for the great popularity of carbolic. Perhaps the price, if sufficiently increased, will tend to lower the record of victims. It is said that both for internal and external burns by this acid scarcely anything equals good old-fashioned cider vinegar.

Contract Surgeons for the Philippines.—The medical department of the army is now in need of some additional assistance in the Philippines, and it is desired that candidates for appointment as acting assistant surgeons will make application to the surgeon-general of the army. Applicants must be graduates of reputable medical colleges, who have had practical experience, since graduation, in hospitals or in private practice. Candidates between the ages of twenty-five and thirty-five are preferred. Candidates should forward with their application one or more letters from well-known professional men, giving testimony as to their character and qualifications. Appointments will not be made through political influence, and letters designed to produce political effect will injure rather than benefit the applicant. All applicants will be examined as to their physical and professional qualifications for service in the Philippines before they are given a contract. Contracts are made for one year, with the understanding that the approved candidate will remain in service for a longer period if his services are required.

Medico-Legal Society, Philadelphia.—At the annual meeting held January 30th, the following officers were elected for the ensuing year: *President*, Dr. A. M. Eaton; *First Vice-President*, Dr. L. H. Adler; *Second Vice-President*, Dr. Samuel Wolfe; *Secretary*, Dr. C. H. Clewell; *Treasurer*, Dr. G. M. D. Peltz; *Librarian*, Dr. J. D. Nash.

Leprosy and the United States.—At last this country has become recognized as a lepra centre. At the last meeting of the Berlin Medical Society, no less a man than Virchow stated that he had never observed and did not know of an instance of contagion in Europe by the intermediary of a leper coming, for example, from the United States.

The Society for the Prevention of Cruelty to Children has won its fight against the State board of charities. The board had asked the courts for a writ of mandamus compelling Mr. Gerry's society to submit to its supervision and inspection. The president of the society maintained that it was not a charitable institution within the meaning of the new constitution, and that it did not come under the supervision or inspection of the State board of charities. The question was brought before the courts, and it has finally been decided by the court of appeals that the society exists for the sole purpose of enforcing the criminal laws to prevent cruelty to children, and can be called a charitable institution only in the same sense that the term would apply to any other corporation organized to aid in the enforcement of any other branch of the criminal law. The society is not over its troubles, however, for a bill has been drafted repealing the provision of the law whereby this city pays $30,000 a year to the society, the ground for this repeal being that the society has been adjudged by the court of appeals not to be a charitable organization, and that being the fact it is no longer entitled to this annual appropriation, which has been made for the ostensible reason that the society was carrying on a charitable work.

The Third Scandinavian Congress for Internal Medicine will be held in Copenhagen on July 1st and subsequent days. The subject for discussion will be serum treatment, which will be opened by Drs. Aaser, of Christiania, Hellström, of Stockholm, and Sorensen, of Copenhagen.

Addition to a Hospital.—A large and new annex to St. Joseph's Hospital at Lancaster, Pa., was opened on January 26th, almost doubling the capacity of the institution by the addition of forty-four rooms and four wards, including one for children, and also a sun parlor for convalescents. The annex is four stories high, and built of brick and stone. It contains a pathological laboratory, and a specially designed operating-room. The hospital is now one of the most complete and perfectly appointed institutions in the State.

Smallpox is spreading in Oklahoma, and it has been necessary to close the post-offices in several towns because of it. In the northwest also the disease prevails, and friction has arisen between the authorities in British Columbia and those in Washington over the disinfection of the mails from Spokane. It is reported from Louisville that smallpox is prevalent in about thirty-five counties of Kentucky, and the State board of health finds itself without the necessary means to fight the disease. The secretary has received the resignations of the county boards of health in at least a dozen counties in which the disease is the most serious, the cause of the resignations in all cases being the inability to fight the disease owing to a lack of money. The protection afforded by vaccination is emphasized by the report of the Connecticut State board of health recently issued. According to this report there were but three cases of smallpox in the State in 1899, and one of these was that of a patient who went to Stamford from this city after assisting in the care of a case here. Dr. Lindsley, secretary of the State board of health, attributes this immunity to the thorough manner in which vaccination has been done in the public schools, and to the wise and effective legislation which permits the exclusion of unvaccinated pupils from the schools.

Bovine Tuberculosis.—Following the report of the special investigating-committee on tuberculosis in animals, a bill is to be introduced into the New York legislature, embracing the following provisions: (1)

That the protection of the herds of this State from tuberculosis and the examination and destruction of glandered horses be placed with the commissioner of agriculture; (2) that the commissioner of agriculture will appoint a farmer well acquainted with the value of cattle, whose duty it shall be to accompany and assist the veterinarian in making examinations of suspected herds and appraise those condemned; (3) that the State can force the condemnation of only such animals as are found to have tuberculosis by physical examination. But if a dairyman elects to have his herd tested with tuberculin, and will enter into an agreement with the State before such examination shall be made, that he will disinfect his premises, and either slaughter or hold in strict quarantine all of the reacting animals and their products, the State will assist him in his efforts to rid his herd of the disease; (4) that the appraisal of condemned animals shall be made at the time of or immediately following the examination; (5) that the State shall pay the owner of all cattle slaughtered under the provisions of this act, known to have been owned in this State at least one year, one-half of the appraised value for all cattle found to have tuberculosis, and full appraised value for all cattle found to be non-tuberculous upon post-mortem examination.

Smallpox in Mississippi.—In a communication addressed to the State senate, Secretary Hunter of the Mississippi State board of health stated that smallpox exists throughout the State, and he advocated the passage of a bill providing for compulsory vaccination.

Illegal Practice by Midwives.—The board of health recently obtained warrants for fifteen midwives in this city who were conducting lying-in institutions without permits. The business is one prohibited by the sanitary code, the births are not reported to the health department, and the deaths are reported from some other place. A number of these women are also strongly suspected of being abortionists.

Cremation of New York's Garbage.—A bill is to be introduced into the legislature providing for the establishment of a crematory plant for the consumption of the garbage of this city. This will abate the garbage-reduction nuisance on Barren Island, and will provide New York City with an adequate and sanitary process of disposing of its garbage.

Health Authorities Close a Library.—A public library in Scranton, Pa., has been closed by order of the board of health, which announces an epidemic of scarlet fever and diphtheria in the city. The board publishes its opinion that the germs of many infectious diseases are carried from house to house by circulating libraries, and so it has issued this order in the hope of stopping the epidemic. The books will be fumigated before the library is reopened.

Study of Tropical Diseases in the Philippines.—By direction of the Secretary of War, a board of medical officers, consisting of Lieutenants Richard H. Strong and William J. Calvert, assistant surgeons, and Acting Assistant Surgeon Joseph J. Curry, United States army, has been appointed to meet at one of the general hospitals near Manila, Philippine Islands, for the purpose of studying tropical diseases as they occur in those islands. The board is to receive its instructions from the surgeon-general, and will be under the immediate direction of the chief surgeon at Manila.—*Boston Medical and Surgical Journal.*

The Medical Control of Marriage.—A Colorado legislator has introduced a bill forbidding the marriage of medically unfit persons. The bill provides for county boards of medical examiners, each to consist of three physicians, no two of the same school, and one at least, if possible, a woman. No licenses shall be granted until a certificate is had from the board that the man is not less than twenty-five years old, the woman not less than twenty-two, and that both are free from dipsomania, insanity or hereditary tendency thereto, tuberculosis, cancer, epilepsy, and syphilis, and that there is no blood relation existing between them.

An Epidemic of Hydrophobia has broken out among the cattle in Center County, Pa. It is believed the disease was spread by a rabid dog which ran wild over an extensive district a few weeks ago. Dr. Riter and other officers of the State live-stock sanitary board are making every effort to control the epidemic, but new cases are continually appearing in unexpected places.

The German Hospital, Philadelphia, has received $10,000 from Henry D. Justi for the endowment of two free beds.

To Restrict Football.—Assemblyman Sullivan purposes offering an amendment to a bill repealing the present boxing-law which would prohibit the playing of football games in this State. He has collected statistics showing that thirty-nine persons have been killed in football games within two years, while two persons only died as a result of engaging in boxing-bouts.

The Effect of Cold on Micro-Organisms.—Prudden has shown that a temperature many degrees below the freezing-point is ineffectual in destroying the typhoid bacillus, but now it has been shown that no known degree of cold will destroy these and some other pathogenic microbes. A paper was read last week before the Royal Society in London, in which a number of startling experiments by Professors Dewar and MacFadyen and Sir James Creighton Browne were reported. In these experiments typhoid, cholera, diphtheria, and other pathogenic bacteria were submitted for twenty hours to the temperature of liquid air (—310° F.), and were shown later by culture tests to be still alive.

Women Nurses in Military Hospitals.—A number of the women who acted as nurses in the army and Red Cross hospitals during the Spanish-American war have appointed a committee to secure the passage of a bill by Congress to provide for the permanent employment of women nurses in army hospitals. Women are so employed now, but only at the will of the army medical authorities. The bill provides "that women nurses in the proportion of not more than ten per cent. of the sick and wounded in general and post hospitals of fifty beds and upward, shall be employed by and constitute the women's nursing-service of the medical department of the army; that there shall be a superintendent of women nurses, who shall be a woman graduated from a general hospital training-school for nurses, having a course of instruction lasting not less than two years, who shall be appointed by the Secretary of War at a salary of $2,000 per annum; that the nurses shall be graduates of general hospital training-schools having courses of instruction lasting not less than two years; that they shall be appointed by the surgeon-general under regulations approved by the Secretary of War; that they shall receive $40 a month when on duty within the limits of the United States, and $50 a month when on duty outside of the limits of the United States." The bill provides, further, that nothing in its terms shall be construed to limit the power of the Secretary of War in time of war or national disaster to avail himself of other duly qualified nurses.

The Sale of Diphtheria Antitoxin by the Board of Health.—A bill has been introduced into the legislature providing that when the board of health has too much vaccine virus and diphtheria antitoxin on hand it may sell the surplus at public auction, but such sales shall not in any one year amount to more than $5,000. The board of health is required to publish a detailed statement every six months showing the amounts of vaccine virus and diphtheria antitoxin that the board has made, the amounts it has used and distributed free, and the amounts it has sold.

The Plague.—In Honolulu, up to January 24th there had been fifty-five cases of plague with forty-one deaths. The health authorities, soon after the disease appeared in the city, adopted the radical plan of destroying by fire every infected building, but on January 20th the fires got out of control and spread from one building to another in the native and oriental quarter, until nearly the entire district was in ruins. Four or five thousand persons were rendered homeless and Chinatown was wiped out, but it is believed that the advance of the plague was stayed.—It is stated, apparently officially, that Rio de Janeiro and Santos, in Brazil, are now entirely free from the disease. A few cases of plague have occurred at Ensenada, Argentina, and the ships of the United States South Atlantic squadron under Admiral Schley were quarantined on that account when they arrived at Montevideo from Ensenada.

Intense Heat in the Southern Hemisphere.—At Buenos Ayres on Saturday and Sunday last the thermometer registered 120° F. in the shade nearly all day. On Saturday there were one hundred and two cases of sunstroke, of which ninety-three were fatal, and on Sunday there were two hundred and nineteen cases, of which one hundred and thirty-four were fatal. In Melbourne, as we noted last week, the weather has been extremely hot, and in South Africa the British troops have suffered exceedingly from the unbearably high temperature. Indeed, the entire globe appears to be warmer than usual, for the winter in this country has been far from severe, in the Klondyke the weather is reported to have been almost mild, and at Davos Platz the season has been ruined by the warm weather, which has turned the snow into slush and has housebound all the guests with pulmonary and bronchial affections.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending February 3, 1900. January 31st.—Surgeon H. E. Ames detached from duty in connection with the *Kearsarge* and ordered to duty on board that vessel February 20th. Medical Inspector J. C. Boyd commissioned as medical inspector from October 25, 1899. February 1st.—Pharmacist R. Waggener detached from the *Pensacola* navy yard and ordered to be examined at Washington navy yard February 13th, for retirement, and then home to wait orders. February 2d (changes by cable from Asiatic Station).—Assistant Surgeon J J. Snyder detached from the *New Orleans* and ordered to the *Isla de Cuba*.

Obituary Notes.—DR. LLOYD WILBUR died at Hightstown, N. J., on January 27th, at the age of seventy-five years. He had recently been appointed superintendent of the census for New Jersey.

DR. JOSEPH F. DEPPEN died at Reading, Pa., on January 28th, at the age of fifty-one years. He was a graduate of the medical department of the University of Pennsylvania.

DR. MARY J. SCARLETT-DIXON died at Westchester, Pa., on January 29th, at the age of seventy-eight years. She was a graduate of the Woman's Medical College of Pennsylvania, and was for twenty years in charge of the Woman's Hospital, Philadelphia.

DR. FRANK HODGSKIN, of Chestertown, Md., was found dead in a hotel at Wilmington, Del., on January 30th.

DR. D. S. MARQUIS died on January 31st at Rochester, Beaver County, Pa., at the age of seventy-nine years. He was the only living charter member of Pennsylvania State Medical College.

DR. ERNEST G. METCALFE died at his home in Brooklyn on February 2d, of nephritis, at the age of forty-nine years. He was born in Canada and was graduated from the Long Island College Hospital Medical School in 1872.

MRS. ANNIE WITTEMEYER died at her home at Saratoga, Pa., on February 2d. She was born in Kentucky seventy-two years ago. At the outbreak of the Civil War she entered the Union army as a nurse and soon became famous for her many practical innovations. Among other things she established a special diet kitchen in army hospitals. After the war she lectured in the interests of missionary societies of the Methodist Church, and was at one time president of the Temperance Crusade, which organization preceded the present Woman's Christian Temperance Union. She was also a prominent member of the Women's Relief Corps, and was at one time its president. She was the founder of the Soldiers' Orphan Home at Davenport, Iowa, and was one of the promoters of the Pennsylvania Memorial Home for Soldiers.

Progress of Medical Science.

Boston Medical and Surgical Journal, February 1, 1900.

Valvular Heart Disease.—Richard C. Cabot, from a study of one hundred and eighty-six cases, states that he thinks he has reason to deny that there is any one form of valve lesion which is constantly associated with the clinical evidence either of hypertrophy or of the lack of hypertrophy of either ventricle. He has seen many cases of marked aortic regurgitation without any evidence of hypertrophy of the left ventricle, and of apparently pure mitral stenosis in which the left ventricle was undoubtedly enlarged, while in most of the cases of mitral regurgitation the enlargement of the heart seemed to affect the left ventricle rather than the right.

Intestinal Indigestion and its Relation to Pulmonary Disease.—Chauncey Rea Burr says that the intestinal tract and the liver are the two points at either one of which, if a departure from the normal occurs, auto-intoxication may result. The intestine becomes a veritable culture tube for micro-organisms, which give rise to toxins, ptomains, and toxalbumins, which pass to the liver, poison its cells, and the filter leaking floods the circulation with poisons. The lungs, being excretory organs, suffer greatly, and the author describes the various pulmonary affections due primarily to intestinal intoxication.

Epilepsy.—Walter E. Paul says that institutional treatment has been inaugurated in several States, and the result of six years' trial is encouraging. The cardinal measures carried out have to do with the diet, hygiene, out-of-door life, and, most important of all, systematic occupation. Very little bromide is used. Some of these institutions have a waiting-list of several hundred eager to be admitted.

Cases of Cholecystotomy.—Edgar Garceau reports three cases. One case was complicated by appendicitis. In one the value of the Murphy button in an emergency was well shown.

Combined Superior and Inferior Poliencephalitis.—G. L. Walton describes a case the etiology and prognosis of which are still undetermined. The further progress will be communicated later.

Journal of the American Medical Ass'n, Feb. 3, 1900.

Etiology of Non-Malignant Rectal Stricture in Women.—In discussing this subject, Reuben Peterson confines his attention to acquired rectal strictures, which he says are much more common in women than in men. He discusses them under the heads: (1) Strictures due to pressure from without; and (2) strictures resulting from organic changes primarily affecting the rectal walls, due to trauma, dysentery, gonorrhœa, tuberculosis, or syphilis.

A Case of Carcinoma of the Nasal Passages.—This case is reported by J. L. Goodale. The patient had had nasal polypi removed at regular and frequent intervals for thirty-three years. There was no evidence of syphilis and the general health had been good. At the age of fifty-one years the growths became carcinomatous, resulting in the patient's death in fifteen months.

Spasmus Nutans.—I. A. Abt reports two cases of this disease which improved under good hygienic conditions and the administration of bromide of sodium. He refers to the frequent confusion in diagnosis between spasmus nutans and eclampsia nutans, a much more serious disorder terminating in epileptic attacks and paralytic conditions.

Electricity in Diseases of the Nose, Throat, and Ear.—W. Scheppegrell reviews the uses to which electricity is put in the treatment of these troubles, and says it is to be hoped that some part of the longer period of study now obligatory in all advanced medical colleges will be applied to teaching the principles of electro-therapeutics.

Bassini's Operation for the Radical Cure of Hernia.—G. M. Woods reports seven cases successfully operated on by Bassini's method, for which he claims great advantages over the Wood and Wützer operations which were formerly the rule. The writer says that in the majority of cases this method results in a radical cure.

Vasomotor System, and the Importance of the Drugs which Act on it, in Ophthalmology.—David W. Stevenson says it would be well if oculists would always report the tension of the pulse with the same care and use the same signs which are used in regard to the eye, and it is even more important that they should know the drugs that will control this tension.

Report of a Case of Echinococcus Cyst of the Nose.—In reporting this case W. K. Rogers says it may be of interest to note that careful inquiry failed to elicit any evidence of intestinal parasites. The patient was under thirty-four years of age and in good health. The writer can find but one other case recorded in medical literature.

Report of Recovery from Traumatic Tetanus.—L. B. Van Camp reports this case as being of interest on account of the exceedingly small percentage of recoveries from tetanus. The case was a very severe one, and the principal treatment consisted of the injection of tetanus antitoxin.

The Code of Ethics.—Samuel C. Busey says the national code of medical ethics is the official declaration of the policies of the regular medical profession of this country, and the more it is studied the more widely will it be accepted as the guide of good conduct.

Acute Suppurative Arthritis of Children.—James E. Moore says that these cases are not generally understood, and many joints and lives are sacrificed on the altar of ignorance, the most common error in this, as in all other joint inflammations, being a diagnosis of rheumatism.

Intranasal Angioma, Bleeding Polypus of the Septum.—W. E. Casselberry reports a case of this nature. He does not think these tumors are as rare as has been represented.

A Preliminary Investigation of the Theory of the Inoculation of Malarial Fever through the Agency of Mosquitos.—By Albert Woldert. A continued article.

Contributions of the Medical Profession to General Literature and Collateral Sciences.—By George R. Highsmith. A continued article.

Medical News, February 3, 1900.

Prophylaxis in Gynæcology: Obstetrics.—James Clifton Edgar discusses this subject under three heads: 1. Pregnancy; 2. labor; 3, puerperium. 1. A good hygiene of pregnancy is of prophylactic importance in two ways: (*a*) By providing the patient with healthy blood; (*b*) by increasing the muscular and the general nutrition, factors of undoubted importance in the prevention of subsequent subinvolution of the uterus and adnexa. 2. (*a*) Limiting the duration of labor; (*b*) the prompt surgical treatment of traumatism, the result of labor; (*c*) and most important of all, the observance of strict asepsis. 3. The patient's position in bed during the whole of the puerperium shall be equally divided during the twenty-four hours between the dorsal, abdominal, and right and left lateral postures. Edgar describes a binder which he uses in the puerperium to sustain the pelvic floor and the lower portion of the anterior abdominal wall. Strychnine in the last part of pregnancy and during the puerperium is beneficial. He also advocates the early use of the vessel in bed or the commode at the side of the bed in the puerperium.

Prophylaxis in Gynæcology.—Henry C. Coe declares that it is to the family physician that the question of prophylaxis is of peculiar interest. It is his province to watch the development of the young girl and to guard her against those numerous indiscretions, harmless in themselves, which are common in careless girlhood. Diet, dress, exercise, menstruation, bowels, should all receive attention. The same principles of prevention should be applied to syphilis and gonorrhœa in the female, as to other communicable affections. Through the general application of the principles of aseptic midwifery the dangers of puerperal sepsis have been minimized. Malignant uterine disease is still, from a prophylactic standpoint, hopeless. The early recognition and treatment of specific infection is an advance in prophylaxis. The whole trend of modern pelvic surgery is conservative, and conservatism is prophylaxis.

Diagnosis of a Case of Cerebral Tumor; Operation.—O. M. Steffenson cites the case of a man, thirty-two years old, with the symptoms of vomiting, headache, partial iridoplegia, choked disc, loss of patellar reflex in the right leg, agraphia, aphasia, alexia, mental stupidity, and listlessness. On operation a growth was found involving the angular, supramarginal, and the base of the first temporo-sphenoidal gyri.

The Relation of the Clinical Laboratory to Modern Surgery.—By Willis G. Macdonald. See MEDICAL RECORD, vol. lvii., p. 212.

The Etiology and Prevention of Uterine Disease before and during Pregnancy.—By W. Gill Wylie. See MEDICAL RECORD, vol. lvii., p. 208.

New York Medical Journal, February 3, 1900.

The Development of the Female Genitals and their Life History.—B. Robinson studies the development of the Wolffian body into the pronephros or head kidney with its ureter and duct, which structure quickly ceases to act in the human fœtus, the mesonephron or middle kidney, which is the kidney of fœtal life, and finally the metanephron or adult kidney and its ureter. He then considers the ducts of Müller and their transformation into the uterus and the vagina. The article contains nothing especially new, but is interesting as being a careful study in embryology stated in terms of modern nomenclature.

A Visit to the Plague Districts in India.—L. F. Barker and J. M. Flint, of the Johns Hopkins Hospital, give a graphic account of their recent travels in the East, and describe the measures taken by the English authorities to lessen the spread of the plague and minimize its inevitable misery and suffering. Their recital, while not without some very grewsome features, contains much that is interesting in itself both from its professional value and its vivid portrayal.

An Experimental Research on the Tensile Strength of the Sciatic Nerve.—G. W. Crile and W. E. Lower have conducted experiments upon dogs; also upon the bodies of patients from one to three days after death. In the adult it was found that a weight of one hundred and forty pounds was required to rupture the nerve.

The Use and Abuse of Poultices.—S. E. Earp advocates the use of flaxseed meal as the ideal constituent. The poultice relieves congestion, reduces inflammation, promotes absorption, diminishes tension, softens incrustations, encourages tissue relaxation, stimulates healthy granulations, deodorizes, and disinfects.

A Case of Neurosis of the Heart: Palpitation.—A case without any special features is described by A. Goltman. He advocates the use of nux vomica as a cardiac tonic. Bromide of potassium is recommended for insomnia, and cold application over the heart during exacerbations.

Aneurism of the Subclavian Artery and its Treatment.—In the case of a man aged forty-five years, A. B. Barkley placed a ligature on the distal side of the aneurism, the exact point being as near the junction of the first and second parts of the vessel as possible. The patient was doing well at last report.

School Hygiene.—G. D. Hamlin describes the unfavorable hygienic conditions found in some of the congested districts of New York City, and makes a plea for a better state of affairs.

Malarial Hæmaturia.—By B. Smith. A continued article.

Philadelphia Medical Journal, February 3, 1900.

Syphilis of the Stomach.—Max Einhorn reports six cases illustrative of three groups of syphilitic disease of the stomach. These groups are: Gastric ulcer of syphilitic origin, syphilitic tumor of the stomach, and syphilitic stenosis of the pylorus. Cases of the last-named group are the most interesting, for failure to recognize the nature of the obstruction would probably result in operation. In both of the reported cases recovery followed the exhibition of potassium iodide, after the usual medical treatment of benign stenosis had proved inefficient.

Notes on the Total Removal of the Human Stomach, and on Gastroplication, with a Late History of Two Cases.—G. Childs Macdonald recalls the four successful cases of extirpation of the stomach by Schlatter, Brigham, the writer, and Richardson, and discusses the reasons why other attempts have been unsuccessful. He advocates gastroplication in cases of loss of nervomotor function of the stomach with resultant dilatation, and refers briefly to two cases in which he recently operated successfully.

Remarks upon the Diagnosis and Surgical Treatment of Perforated Gastric Ulcer.—Maurice H. Richardson discusses the symptoms of perforation of the stomach and its operative treatment, and reports at length four cases. In two of these cases an operation was performed and recovery occurred in one; the third case, which terminated fatally, was not operated upon; the fourth case was one of acute hemorrhagic pancreatitis, which is reported as an illustration of the diagnostic difficulties in certain cases.

Latent Cancer of the Stomach.—William Osler and Thomas McCrae report seven cases of cancer of the stomach unaccompanied by indicative symptoms. In three cases the disease involved a large part of the stomach, in two the pylorus, and in two the cardia. In one case the œsophagus was involved and in another the duodenum. In three cases there was ulceration, and in five metastases were present.

Acute Dilatation of the Stomach.—Henry Wald Bettmann says this condition is marked by vomiting of large quantities of a bile-stained fluid, distention of the abdomen while the right hypochondrium remains flat, collapse, and death from exhaustion. The treatment should consist in supportive measures, early resort to lavage, and rectal feeding. Nothing should be swallowed until the vomiting is under control. Narcotics are injurious.

After-History in a Case of Successful Total Extirpation of the Stomach.—Charles Brooks Brigham removed the entire stomach for cancer on February 24, 1898 (*Boston Medical and Surgical Journal*, May 5, 1898). The patient, a woman, sixty-eight years old, is now in excellent health, eats three meals a day of ordinary food, and takes no medicine except a dose of castor oil once in ten days.

Histological Studies Relating to the Early Diagnosis of Cancer of the Stomach.—John C. Hemmeter discusses the diagnosis of cancer of the stomach by means of microscopical examination of scrapings from the mucous membrane. The diagnosis is based upon changes in the character of mitoses peculiar to the cells in malignant neoplasm.

Diagnosis of Gastric Ulcer with Report of Cases.—Frank H. Murdoch gives three diagnostic signs of ulcer in patients with dyspeptic symptoms: (1) Hæmatemesis, (2) severe pain relieved by orthoform, (3) a constant tender point in the epigastrium with or without a corresponding tender spot to the left of one of the lower dorsal vertebræ.

Auto-Insufflation of the Stomach.—C. D. Spivak describes a tube with a lateral opening so placed that when the tube is in the stomach the side opening is situated in the anterior portion of the buccal cavity. The end of the tube is now compressed, and the patient, by closing the lips around the tube and inflating the cheeks, blows air into the stomach.

The Indications for Surgical Interference upon the Stomach.—James H. Dunn says that operations upon the stomach are often made in unsuitable cases, and in suitable cases are made too late, and lays down some general rules to guide the surgeon in his selection of cases for operative treatment.

Direct Electrization of the Stomach, Especially by High-Tension Faradic Currents.—Boardman Reed reports two cases of hyperchlorhydria in which the faradic current was applied directly to the mucous membrane. In the second case a high-tension coil was used with marked success.

On the Newer Applications of Gastro-Enterostomy in the Treatment of Diseases of the Stomach.—Robert F. Weir reports three cases of gastro-enterostomy conjoined with entero-anastomosis performed after the method described by him in the MEDICAL RECORD, vol. liii., p. 541.

Stricture of the Œsophagus Resulting from Typhoid Ulceration.—John S. Pyle reports a case of this nature in which dilatation by hydraulic pressure, applied by means of an instrument of his own invention, was entirely successful.

Perforating Gastric Ulcer and its Surgical Treatment.—Martin B. Tinker presents an extensive study of the literature of this subject, which contains reports of two hundred and thirty-two cases, with a mortality of one hundred and nine, or 48.81 per cent.

A Case of Traumatic Stricture of the Œsophagus Treated by Electrolytic Dilatation.—Arthur G. Minshall reports a case of recent stricture, produced by the accidental swallowing of a solution of caustic potash, cured by electrolysis.

Motivity of the Stomach.—Fenton B. Turck discusses under this title the etiology, pathology, symptomatology, and treatment of motor insufficiency of the stomach.

Gastroplication for Dilated Stomach.—Randolph Winslow reports a case of this operation, performed with success in the person of a man aged sixty-four years.

The Surgical Treatment of Diseases of the Stomach.—William J. Mayo discusses the operative treatment of gastric disorders, his conclusions being partly based upon his own experience in about sixty cases.

Gastrosuccorrhœa.—H. W. Lincoln discusses the etiology, symptomatology, and treatment of both the acute and the chronic form of Reichmann's disease.

Case of Vertical Stomach.—George Macy Ekwurzel describes an instance of this rare anomaly discovered at autopsy.

British Medical Journal, January 27, 1900.

Cases Complicated with Mental Disorder Treated by Thyroid Extract.—Richard R. Leeper says that treatment with thyroid extract is imperative in all cases of insanity showing a steadily downward course, in which there is reason to suspect thyroid insufficiency. In view of the cumulative property of the substance its effects must be carefully watched. This extract owes its remedial results to its direct stimulation of the cortex and the increased metabolism thereby induced among its elements. The rise of temperature is, however, not the most constant symptom of reaction. To the increased pulse-rate and quickened circulation must presumably be attributed most of the good effects of the treatment. The writer concludes by saying that when we know more of the functions and the mode of action of the secretions of the ductless glands, we shall find a solution to many of the problems of psychiatry.

Remarks on the Pure-Air Treatment of Phthisis at Home.—Under this heading Arthur Ransome discusses the treatment of tuberculous patients who are unwilling or unable to leave home. He says that the advantages of "open-air" treatment for this disease are undoubted, but that it cannot be carried out in the patient's own home save under certain stringent conditions, such as a residence drained, ventilated, and furnished with a special view to the treatment, strict attention to asepsis, carefully regulated feeding, the treatment of accidents, suitable amusement, etc. The writer sums up his conclusions by saying that these conditions cannot be met without the constant supervision of a medical man and the services of a trained nurse or of an intelligent and trustworthy attendant. For the poor, suitable sanatoria should be provided at the public expense.

The Application of Bacteriology to Public Health.—Walter C. C. Pakes discusses this subject under two headings, viz., Diagnostic Examinations, including tuberculosis, diphtheria, typhoid fever, etc., and Preventive Examinations, including the examination of water, milk, etc.

The Continuity of the Toxic Process in Fatal Cases of Diphtheria.—John Biernacki gives some deductions from his study of the blood-pressure curve in cases of diphtheria. He says the gravity of this disease may be in part explained by the diverse action of its toxin, which causes a fall in blood pressure and also a change in the cardiac and renal tissues.

Poisoning by Sodium Salicylate.—Gordon Sharp quotes a case in which 130 grains of this drug were taken at one time, in order to prove that the salicylate within reasonable limits is not a cardiac depressant, as is generally taught in the text books, but is, on the contrary, often a calmative of great usefulness.

Poisoning by Oleum Eucalypti.—Frederic C. Wood reports a case in which a child, aged three years, swallowed between two and three teaspoonfuls of oleum eucalypti. The symptoms were identical with those of opium poisoning, except there was no stertorous breathing. The child recovered.

Fracture of Both Clavicles.—In this case, reported by William Semple Young, the patient was a boy, aged six years. The patient was strapped and treated in the recumbent position, with the result that in three weeks the bones united well.

The Removal and Transport of Cavalry Wounded.—T. F. S. Caverhill discusses at length the various ways in which wounded cavalrymen may be most promptly and efficiently aided by means of horse litters, etc.

Formalin in Rodent Ulcer.—F. Wyatt-Smith reports this case, for which operation was refused, and which he treated with a twenty-per-cent. solution of formalin in glycerin and water, with excellent results.

A Case of Enteric Fever with Acute Nephritis.—H. Reynolds Brown reports this case as being a rare complication. The only treatment seriously attempted was by the hot pack and intestinal antiseptics.

The Pathology and Treatment of Appendicitis.—By C. B. Lockwood. See MEDICAL RECORD, vol. lvii., p. 243.

Pericarditis.—A clinical lecture, by Graham Steele.

The Lancet, January 27, 1900.

A Clinical Lecture on Sleeplessness.—W. H. Broadbent discusses this question from the standpoint of the difference in the vascular conditions of the cerebral cortex in the sleeping and waking states. Common causes of insomnia include extremes of temperature in the feet, both high and low vascular tension, and flatulent dyspepsia. Many cases are cured by a relief of these conditions, while in others it may be necessary to alter entirely the manner of living of the individual. Insomnia often follows influenza, and if the case is at all obstinate, an opiate with hyoscyamus is better than the bromides, chloral, or trional. In the insomnia of the later stages of an alcoholic debauch, strychnine with digitalis is indicated.

Excision of the Spleen for Injury.—Recital of a case by O. St. J. Moses. Dangers of this operation are peritoneal infection, and especially bleeding from vessels at the hilum. Sharp probes were passed at right angles through the stump of the pedicle, their ends protected by cork resting on the surface of the abdomen. The spleen was cut away external to the outer ligature, and the remaining stump treated like the stump of the uterus in a Porro operation. The patient recovered.

The Process of Digestion after Resection of about Six Feet of the Small Intestine.—Carl Schlatter says that the removal of this length of bowel closely approaches the critical line between recovery and death. In his own patient the loss of this length of ileum did not seem to make the slightest difference in digestive function. The patient had a severe general urticaria five days after operation, but no other untoward symptom.

Pott's Disease or Fracture of the Vertebræ.—W. R. Townsend reports the case of a girl, aged six years, who after a fall presented a bony prominence in the back of the neck accompanied by dyspnœa and the habit of supporting the head by the hand placed under the chin. Kyphosis was marked, and there was a depression of the upper cervical vertebræ. The patient was seen by several physicians. Both diagnoses named in the title were made.

Deaths Under Chloroform.—J. Edmunds insists upon the same precision of dosage with chloroform as with morphine or strychnine. An improved Krohne inhaler affords a true volumetric dosage. Administration should always be begun with small volumes of chloroform-air, such as to cause neither cough nor resistance.

A Case of Rectal Deformity.—I. G. Modlin reports a case of a woman with a well-formed perineum and a dimple at the site of the anus, but without any opening or sphincter. The vulva, externally normal, was occluded by a movable partition visible on separating the labia. The urethra, vagina, and rectum all opened into one common vulva.

Some Remarks on the Diaphragm.—R. Lee refers to a symptom which he finds very common in influenza. It is a pain around the lower part of the thorax, which he believes to be due to a nervous affection of the diaphragm. Spasm of this muscle may cause the peculiar dry cough of the disease named.

The Use and Abuse of Preservatives.—S. Rideal gives the results of experiments upon milk with boric acid and formaldehyde. Coagulability depends somewhat upon the percentage of acidity, and any preservative is obviously more efficient if added at the time of milking before changes have already begun.

Myoidema in Pulmonary Tuberculosis.—H. Walsham finds this physical sign only in cases attended by great wasting, and believes it to be valueless as an early sign of pulmonary tuberculosis. It is, however, a good index of the actual amount of wasting which has taken place.

The Pathology and Treatment of Appendicitis.—C. B. Lockwood believes that bacterial infection is the great exciting cause of the malady, no matter what type the symptoms may assume. He advocates the oblique incision parallel to the outer half of Poupart's ligament.

Depilation by Roentgen Rays.—Neville Wood shows that exposure to the x-rays may become available as a means of depilation. From thirty to forty exposures are necessary to secure permanent alopecia.

Medical Press and Circular, January 24, 1900.

The Role of the Physician in Renal Affections.—Professor Lancereaux says the physician must in every case of renal disease and under all circumstances meet two indications which never vary: To treat the renal lesion or functional trouble, and to treat the intoxication which is the consequence of the affection. Always and invariably the primary malady localizes its effects at the outset in one only of the anatomical elements composing the kidney. In fever the epithelium alone suffers; in late syphilis and saturnism the vascular connective tissue is affected. In epithelial nephritis cantharides acts as a specific on the epithelium; in connective-tissue nephritis preparations of iodine are capable of modifying the new sclerosed tissue. The lesions of uræmia are focussed on the digestive tract; there are two kinds of symptoms, digestive and nervous. Rules of treatment are laid down.

A Comparatively Rare Injury to the Distal Phalanx of the Finger.—John Ewens records three instances of injury involving the ungual phalanx, which is bent forward as in dislocation by suddenly impinging with great force upon some hard immovable substance. There is no dislocation, nor is it likely that there is rupture of the tendon in the usual way. It is suggested that the termination of the tendon may be torn through close to its insertion, or more probably the periosteum may be raised from the bone.

The Therapeutic Value of Salophen.—T. Poyntz Wright recapitulates English experiences and has personally found salophen of great value in rheumatoid sciatica, while its great value lies in the treatment of influenza. It is a perfect substitute for salicylic acid and its compounds without possessing the disadvantages.

Diphtheria.—By William R. Smith. The third of the Harben Lectures.

Wiener klinische Wochenschrift, Jan. 11 and 18, 1900.

Polioencephalitis Superior Acuta and Delirium Alcoholicum as an Introduction to Korsakow's Psychosis without Polyneuritis.—Emil Raimann reports a case of this kind in a man thirty-seven years old, who had been addicted to the use of alcohol for years. He was attacked simultaneously by alcoholic delirium and by local and general somatic disturbances. In the right eye there occurred an external and internal ophthalmoplegia. There was also paralysis of the abducens of the left eye. This paralysis lasted for a considerable length of time. Consciousness was much disturbed. Peripheral neuritis was not present. The almost simultaneous occurrence of polioencephalitis and alcoholic delirium was not a chance event. The chronically poisoned organism had only waited the opportunity to express itself. The patient suffered not only from loss of memory, but from delusions. From this attack he made a good recovery.

Contribution to the Knowledge of Chyliform Ascites.—F. Micheli and G. Mattirolo state that the pathogenesis of the various so-called milky effusions must be different, and their origin must depend on varied etiological factors. They then give the quantitative constituents of various effusions in which the quantity of fat or rather the ethereal extract—fat, cholesterin, lecithin—was never greater than 1 gm. In some of these effusions there was not enough fat to cause opalescence—1.5 gm. bring necessary for that (Letulle). Experiments were made which proved that opalescence in these cases depended on lecithin. It now remains to demonstrate what rôle lecithin plays in the condition of opalescence of true fatty effusions (ascites chylosus et chyliformis).

The Etiology of Congenital Defect of the Pectoralis Muscle and the Elevated Position of the Scapula.—Hermann Schlesinger says that defect of the pectoralis generally consists in the absence of the sterno-costal part, while the clavicular part is present at least in part. The right side is generally affected. There is an apparent flattening of the sternum on the affected side. The skin of this side is sometimes poor in fat with few hairs. Schlesinger reports several cases of this nature, and thinks the cause of the defect is due to arrested development. The arm on the affected side can be moved for the most part as well as the opposite one, the deltoid generally assuming the function of the defective muscle.

Hæmolysin and Antihæmolysin.—Rudolf Kraus tabulates the results of numerous experiments which prove that the different micro-organisms develop hæmolytic poisons in relation to the blood-corpuscles of different animals, and that normal blood sera can suspend this hæmolytic influence. The antihæmolytic influence of normal serum is to all appearances due to the influence of a ferment.

Some New Drugs in the Therapy of Phthisis.—Jul. Pollak, in this list, first mentions duotal, which is valuable in its influence on the appetite. Pyramidon is used for its antipyretic action, one of its chief virtues being that it has no baneful effect on the heart. Heroin hydrochlorate has a most beneficial control over the cough of tuberculosis.

A Note on the Subject of Infantile Pseudo-Bulbar Paralysis.—M. Bernhardt states that H. v. Halban in his monograph on "Infantile Pseudo-Bulbar Paralysis" has reviewed the literature on this subject, which he himself has attempted to supplement.

A Case of Traumatic Periodic Paralysis.—Julius Donath records this case, stating that von Hartwig was the first to describe this obscure disease.

Münchener medic. Wochenschrift, Jan. 9 and 16, 1900.

Convulsions in Childhood.—J. Lange writes that convulsions in childhood can be classified as organic and functional, and that functional convulsions may be further subdivided into sympathetic and idiopathic. He adds that eclampsia is not an essential disease, but only a symptom, and that its diagnosis as such must disappear from the index of text-books even as fever, vomiting, or headache. Convulsions are frequently caused by foreign bodies in the nose, throat, œsophagus, ear, larynx, and trachea; by irritation of the skin; by many affections of the digestive tract. They often occur at the beginning of an acute, febrile, infectious disease, and are designated as an initial infectious eclampsia. The chronic infections in which they are most common are rachitis, syphilis, and scrofula. Certain poisons excite convulsions, viz., opiates and chloral hydrate. Carbon dioxide plays the greatest rôle in the mortality statistics of convulsions. In the attack the clothes should be loosened, baths may be given, leeches applied to the neck. Bromides are excellent sedatives in this trouble. Phosphorus is sometimes given.

Treatment of Neurasthenia.—Otto Dornblüth advises a careful physical examination as the first step in the treatment of neurasthenics. A careful discrimination should be made between acute and chronic forms of the affection. Rest stands foremost in the treatment of acute neurasthenia—rest in bed being most efficacious. This can be continued from eight days to six weeks. Next in importance comes diet, which in most cases needs to conform only to normal nourishment. Hydrotherapy is very beneficial, as well as electricity—the application of a weak faradic current being preferable. The patient's confidence should be gained, and special attention should be paid to his mental influences. As to drugs the author inclines to the use of sanguinol in anæmic cases, and arsenic in cases of the arthritic type. However, appropriate treatment must be suited to the individual case. Codeine is used in depressive forms. As to the treatment of chronic cases, many are benefited by that just described for the acute form. Those resulting from some form of traumatism should of course have the injury or its results attended to first, when often a desire to resume the normal life will naturally follow.

The Present Reputation of Salt-Water Infusions, with the Description of a Complete Infusion Apparatus.—Häberlin states that infusion is the younger sister of transfusion. In general, the infusion of salt water is indicated in all cases when the heart pump lacks the necessary quantity of blood; when the body is exsiccated through the loss of fluid; when the input of fluid is below par, when the blood and the tissues are saturated with poisons; and when the strength of the heart is weakened, the glandular capacity diminished, or the nervous centres are stupefied. The contraindications generally depend upon heart insufficiency with cyanosis, œdema of the lungs, and a high degree of dropsy with nephritis.

The Treatment of Suppuration of the Frontal Sinuses.—Winckler declares that all accepted operations should be carefully considered in every case of this kind, and that the one most appropriate be used without regard to the operator's penchant for any one particular method. In the after-treatment of his own cases, he no longer flushes out the wound but carefully dries with a gauze tampon, making use of insufflation and inhalation.

Bleeding of the Endometrium from Sclerosis of the Uterine Arteries.—M. Simmonds describes this affection as "apoplexia uteri" (Cruveilhier), and believes that there is a close connection between alterations in the vessels and menorrhagia. Undoubtedly arteriosclerosis is the etiological factor of importance in hemorrhage of the uterus in old women, and after all therapeutic measures fail, resort will have to be had to the extirpation of the organ.

A Second Case of Removal of the Shoulder-Girdle for Sarcoma of the Scapula.—Th. Kölliker refers to the former case with scapular sarcoma on which he operated. The patient died about two years after the operation, of metastases in the brain and lungs. The present patient recovered quickly from the operation, but died six months later from influenza-pneumonia. There was no recurrence.

Suture of the Heart as a Typical Operation.—Emil Rotter thinks that in cases of heart injury, when there is nothing to lose but much to gain, a typical operation should be accepted by surgeons. The heart should be well exposed, and the operation be accomplished as quickly and with as few assistants as possible. He carefully describes the technique, giving illustrations.

A Case of Puncture of the Ear with Loss of Brain Fluid.—Löhnberg reports this case, in which he made careful chemical experiments, proving that the fluid exuding from the wound originated in the brain. The injured part was kept carefully bandaged and strict rest enforced, and the patient was discharged cured at the end of a month.

A Case of Land Scurvy.—M. Rothschild describes a case of sporadic scurvy in a woman twenty-five years of age. None of the ordinary etiological factors was present, unless we accept the damp, cold weather prevailing at the time, as having a causative influence.

Adeno-Carcinoma of the Cæcum; Invagination, Resection, Recovery.—Krecke cites the case of a woman sixty-three years old, on whom resection was successfully performed. It is now a year since the operation, and there has been no trace of recurrence.

Experimental and Clinical Experiences with Orthoform.—August Luxenburger concludes that orthoform is an absolutely harmless anæsthetic which neither diminishes secretion nor delays wound healing.

F. V. Birch-Hirschfeld.—Obituary by Professor Kockel.

Deutsche medicinische Wochenschrift, January 11, 1900.

The Diagnosis of Imbecility in Early Childhood.—Martin Thiemich discusses the various means of testing the mental condition of very young children. These consist in the determination of pain sense, taste, and attention or reaction to non-painful stimuli. For the first he uses a needle, an imbecile child often showing no signs of pain even when pricked repeatedly. For the second he employs solutions of saccharin, quinine, hydrochloric acid, and common salt. A normal infant will usually express satisfaction when the tongue is moistened with the first, but will resent the application of bitter, sour, or salt solutions. As regards attention one must note the possibility of attracting this and also the length of time it can be fixed upon a given object. Later diagnostic factors are the development of the sense of cleanliness and the beginning and progress of the power of speech.

The Taking of Nourishment by the New-Born.—H. Cramer relates certain experiments made to determine the amount of nourishment necessary to maintain the physiological weight of infants during the first ten days of life. He also estimated the suction force necessary to draw milk from the breast and from the nursing-bottle respectively, and suggests that the difference in these forces may be of significance as regards metabolism in infants.

The Valuation of Tetanus Antitoxin and its Employment in Man and Animals.—E. Behring has succeeded in preparing a stable tetanus virus for use in estimating the potency of the antitoxin. He asserts that the mortality of tetanus can be reduced to fifteen per cent., provided the antitoxin is given in doses of not less than one hundred units not more than thirty hours after the appearance of the first symptoms.

The Physical Determination of Unilateral Deafness.—H. Röhr discusses Lucae's instrument for the detection of simulated unilateral deafness (the "interferenzotoscop"), and concludes that it is unreliable. In some cases in which deafness is present the apparatus fails to indicate it, and in others it points to the existence of deafness when the hearing is good.

On a Possibly Serious Skiagraphic Error.—By Carl Beck. See MEDICAL RECORD, vol. lvii., p. 65.

Vratch, January 1 and 8, 1900.

Treatment of Inflammatory Affections of the Uterus and Adnexa with Hot-Air Douches.—In a preliminary communication, A. M. Mansvetoff describes an apparatus for the preparation and application to the vagina and uterus of dry heat. The temperature of the air is from 50° to 60° C. (122° to 140° F.), and the douches are given for one or two hours every day or every other day. The author has never seen any injurious effects of the douches, but on the contrary claims for them the following advantages: (1) They quickly and for some time quiet pain in the pelvic organs; (2) they soothe the nervous system, induce sleep, and increase the appetite; (3) they lower the temperature, pulse, and respirations, when these are elevated; (4) they influence favorably the menstrual flow; (5) they facilitate the perfect removal of the products of inflammation; (6) they increase secretion from the uterine cavity.

Anæsthesia by Injection into the Spinal Canal.—Y. B. Zeldovitch reports four cases in which operations were performed under anæsthesia induced by the injection of a solution of hydrochlorate of cocaine into the spinal canal. He also performed a number of experiments on dogs to determine whether the dose of the injected substance might not profitably be increased so as to increase the anæsthetic action and avoid the unpleasant by-symptoms sometimes observed to follow the puncture of the needle. As a result of his experience he concludes with Bier that, in the present stage of the method, it ought to be employed only in cases in which anæsthesia by chloroform is especially contraindicated.

Vir Effeminatus.—A. S. Tauber reports with illustrations a case of hermaphroditism in a person twenty-two years old. The subject was apparently a tall, well-developed woman, with long hair on the head and no beard. The breasts were large and pendent. There was scanty, irregular menstruation. On palpation of the abdomen a body resembling the ovary could be distinctly felt on the right side. There was an imperfect vagina, together with a female urethra. But with this there was a scrotum containing two bodies resembling testicles, and the clitoris was greatly developed, resembling a penis. The voice was of a masculine character.

Corporal Punishment in Russia on the Eve of the Twentieth Century.— By D. N. Zhbankoff. A continued article.

Post-Partum Sloughing of the Uterus.—By V. G. Bekman. A continued article.

La Riforma Medica, January 9–18, 1900.

The Typhoid Bacillus as Found in the Blood.—Aldo Castelani concludes from his experimental researches that the bacillus is more frequently found in typhoid cases than is usually supposed. By diluting the blood with peptonized and slightly alkaline broth, the bacilli sowed in it usually developed great mobility, giving the characteristic turbid appearance to the culture medium. In some cases, however, they were agglutinated on the bottom and sides of the vessel, leaving the liquid almost entirely clear.

Fibroma Molluscum.—Sergi Trombetta reports a case in a boy aged sixteen years. The affection dated from infancy, and began as a small subcutaneous swelling in the right tendo Achillis, which gradually increased in size. Actual condition showed the right foot in an atrophic condition, even the bones being smaller than normal. A soft, fluctuating mass was situated on the tendon. It was removed and was found to be a fibroma molluscum. The histological examination is described in detail.

Necrobiotic Ischæmic Infarction of the Lung.—Giovanni Cagnetto reports a case and gives a minute description of the anatomico-pathological condition found at the autopsy. He believes the condition to have been due in the first place to the action of Fränkel's diplococcus, found in abundance in the lung tissue, in causing inflammatory lesions in the blood-vessel walls, and secondarily to a resulting thrombosis.

Neuralgic Genital Herpes.—Cesare Casarini records a case in which an infective origin could be excluded. It was held to be due to nervous origin, and related to phenomena of altered sensibility in the superior interior region of the thigh through the genito-crural nerve, and that of the posterior region through the femoral branch of the inferior gluteal.

Rare Anomaly of the Arteries in the Arms.—G. Mollica describes an unusual arterial condition, and holds that surgeons should have a thorough knowledge of abnormal as well as normal conditions of the body.

Rivista Critica di Clinica Medica, Jan. 6—20, 1900.

Common Sense in Practical Medicine.—Augusto Murri, in a lecture to medical students, urges greater individual thought on the part of students and physicians, and greater exactness in the use of language. To the saying, "He who does not learn how to speak forgets how to think," he adds, "and he who forgets how to think cannot learn to operate." Well-trained minds can best grapple with the problems of medicine. The learning of technical details, such as feeling the pulse, the weighing of excreted urea, the measurement of the viscera, are of no use unless one is able to appreciate the significance of the counting, weighing, and measuring. The spirit of the article might be summed up in the words: a physician's brain should be of good quality, well trained, and in constant use.

Puerperal Eclampsia.—Ernesto Pestalozzi makes a distinction between true, concealed, and pseudo-eclampsia. The true and the pseudo are convulsive forms of the auto-intoxication; the concealed form is due to this auto-intoxication, but the convulsions are inhibited by some cause which prevents the cortical substance from acting, such as a cerebral hemorrhage, for instance. In pseudo-eclampsia the auto-intoxication has a secondary rôle, the convulsions apparently being due to the stimulus of a cerebral tumor, or a meningitis for example, upon a nervous system rendered particularly susceptible by pregnancy.

Surgical Intervention in Marked Dilatation of the Stomach.—A. Cardarelli thinks that when a diagnosis of simple stenosis of the pylorus has been made, surgical measures should be at once resorted to. Even when the diagnosis is not quite clear, a recognition of the fact that there is impotence of the stomach walls, shown by the impossibility of its emptying itself of its contents, and permanent retention, justifies operative procedures. Marked dilatation calls for surgical intervention. The author reports four cases.

Acute Hemorrhagic Poliencephalitis from Influenza.—C. Bozzolo reports two cases in which headache, stupor, rigidity of the neck, pupillary disturbances, vomiting, and Kernig's symptom all pointed to meningitis. It was, however, a severe form of influenza, which the author believes induced an acute hemorrhagic poliencephalitis. The diagnosis was purely clinical.

French Journals.

Cardiac Insufficiency and Forced Heart.—Pierre Merklen understands by *cœur forcé* an asystolic state beginning with functional troubles, associated with feeble and persistent dilatation, which have come on suddenly after overtire or violent effort. A distinction must be made between cardiac insufficiency, forced heart, and asystole, which are often regarded as synonyms. Insufficiency is a term often employed by foreigners, he thinks, to characterize feebleness and dilatation with their consequences, venous stases.

It is the equivalent of the French term asystole. Cardiac insufficiency is a state much more than a disease. It should be early discovered, since treatment in cardiopathies is, before all else, prophylactic hygiene. If the patient belongs to the working class, he should give up all but sedentary occupation; if to the wealthy class, he should renounce an active life, and adapt himself to general hygiene applicable to cardiacs.—*La Presse Médicale*, January 17, 1900.

Potatoes in the Diet of Diabetics.—A. Mossé finds that while potatoes have been rigorously excluded from the dietary, and exceptionally allowed, they have recently come to be recommended as a substitute for bread. He has studied their effect upon the urine, and found in one case followed for two months that the sugar diminished after their administration. As a general rule, it has been found that potatoes which swell up and burst open, or disintegrate when cooked in water, contain more flour than those that remain firm—the latter containing a larger proportion of albuminoid matter. According to authors quoted the central portion of fresh potatoes, which have reached perfect maturity, is the most watery, the poorest in flour, and the richest in azote matter, and hence this part should be chosen for diabetics.—*Bulletin Général de Thérapeutique*, January 15, 1900.

Treatment by Cold Baths in the Typhoid Fever of Children.—F. Glénard, to give an idea of the mortality under drug treatment, reviews 1,745 cases studied and finds the mortality fifteen per cent. Under strict bath treatment, the results of a number of reporters gives a total of 503 patients with 18 deaths, or 3.5 per cent. Studying cases treated by baths or moist temperature lower than that of the patient's fever, but not in a systematic manner, he arrives at the conclusion that eleven per cent. represents the mean mortality. Other statistical data are given, and the article is to be continued.—*Revue de Thérapeutique*, January 15, 1900.

Ichthyosis.—Hallopeau and Leredde consider the disease incurable, but think much may be done to keep down the scales as they are produced, and give comfort to the patient. A seeming cure can be secured by inunctions of oil of sweet almonds with vaseline and five per cent. of boric acid, or two per cent. of salicylic acid, or five per cent. of sulphur. In ichthyosis hystrix the concretions may be removed by raclage.—*Journal des Praticiens*, January 20, 1900.

Jour. of Cutan. and Genito-Urinary Diseases, Feb., 1900.

Classification of Tumors.—B. H. Buxton gives with diagrams a new classification. Epithelial tumors he thinks are better classified according to the structure rather than the origin of the epithelium from which they are derived. There are three main groups: flat stratified, cubical, and flat single, calling the benign tumors derived from them papillomas, adenomas, and benign endotheliomas, and the malignant ones epitheliomas, carcinomas, and malignant endotheliomas. He objects to the Greek ending "omata" for the plural, since the termination "oma" has been adopted into our language.

The Rôle of Pus Organisms in the Production of Skin Diseases.—George T. Elliot reviews at length the whole literature, from which it is evident that although micro-organisms, especially the staphylococci and streptococci, are the particular cause of suppuration, yet many other factors both internal and external are active. Contradictory results are obtained by different observers, and chaos still exists. Micro-organisms, while the general cause, are not the exclusive cause.

Prostatitis and Seminal Vesiculitis.—Charles H. Chetwood gives his experience combined with that of E. L. Keyes. Chronic prostatitis is differentiated from prostatorrhœa, and both from seminal vesiculitis. Figures show the employment of a new rectal irrigator—a modification of the Tuttle and Kemp tubes. The treatment of seminal vesiculitis resembles that of prostatitis. During acute inflammation, rest, bland diet, hot sitz-baths, etc., are recommeded. Massage and rectal douches are only proper in the chronic stages.

Pediatrics, February 1, 1900.

The Estimation of the Leucocytes of the Blood as an Aid in the Diagnosis of Diseases of Children.—George D. Head believes that the leucocyte counts in the blood of children affected with certain diseases are as characteristic and fixed as in diseases of adult life. Pyæmic infection is usually followed by well-marked leucocytosis; in appendicitis with pus formation a well-marked increase of white cells is found, while in intestinal obstruction there is rarely an increase, so that this would be of value in differential diagnosis. In the first week of typhoid the count is normal or below normal; in the second, third, and often the fourth almost always below normal. This would distinguish the condition from appendicitis, osteomyelitis, enterocolitis, etc. Cases are given.

Two Cases of Infantile Hemiplegia Following Convulsions in Scarlet and Malarial Fever.—E. B. Montgomery quotes the opinions of many authors, and gives two histories which have led to opinions of his own not in strict accord with those prevailing.

Report on the Cause and Prevention of Infant Mortality.—By Ernest Wende. See MEDICAL RECORD, vol. lvi., p. 719.

The Therapeutic Gazette, January 15, 1900.

The Therapeutics of Tuberculosis.—Lawrence F. Flick says the therapeutics may be predicted upon: (1) The predisposition and resisting-power and antecedents of the patient; (2) the tubercle bacillus; (3) the disease germs which set up mixed infection and so may be subdivided into germs which run an independent course with the tubercle bacillus. The predisposition may be natural or artificial. When natural, little can be done to remedy it, and a fatal termination is usual. Artificial predisposition, such as is produced by alcohol, may be abolished by removing the cause. We should never say that a certain drug is useless, but we should know when and how to use it, and more attention must be paid to the use of adjuvants than to endeavors to find specifics. One remedy which brings comfort and encouragement is creosote. It is best given in large draughts of hot water before meals. The dose should be gradually raised up to gtt. xl.-l. three times a day, the hot water being likewise increased; with the maximum dose a pint being given.

The Treatment of Gonorrhœal Rheumatism.—Charles H. Frazier regards the condition as an infecting arthritis, in some cases the gonococcus alone being the exciting cause, in others we have a mixed infection. The first is the milder form. Firm pressure should be applied to the elevated limb, preferably by means of a rubber bandage, or strips of adhesive plaster, with gentle massage. If these means fail, aspiration and irrigation should be employed. In empyema of the joint, immediate arthrotomy should be done, with antiseptic irrigation and drainage. In phlegmon of the joint the pain is more pronounced. Ankylosis is almost sure to follow improper treatment.

Proper immobilization should be carried out by means of a plaster cast. Acupuncture is an efficient means of relieving congestion. As to internal remedies it is doubtful if they exert any specific effect, but the urethral lesion should be simultaneously treated.

Chloretone a Safe Hypnotic.—W. M. Donald says chloretone is made with caustic potash, chloroform, and acetone. It has the odor of camphor. It is best given in tablet form. It is of considerable value in well-selected cases in doses of gr. xii.–xv., repeated within two hours if necessary. Its relative value has not been determined. The case of a morphine habitué is related who took gr. xlviii. in one day without untoward symptoms. In all gr. cxx. were administered, and sleep extending over the greater part of five or six days was secured.

Electrolysis for Aortic Aneurism—Another Case and a Report of One Previously Reported.—H. A. Hare gives the history of a case, with illustrations, one showing the results after three years' treatment. In statistics published by himself and Holder of 951 cases of aneurism of the thoracic aorta, 570 occurred in the ascending arch, 104 in the transverse, and 110 in the descending portion.

The Use of Creosote in Pulmonary Tuberculosis.—Irwin H. Hance says that when creosote is tolerated it is indicated in any form of tuberculous affection of the lungs, but more particularly in afebrile cases with free expectoration. It should never be forced at the expense of the patient's digestion. The carbonate of creosote has given satisfactory results in doses of gtt. xxv. after meals.

The Use and Abuse of Drugs in Phthisis Pulmonalis.—W. G. Schauffler says individual idiosyncrasy must be taken into account. Cod-liver oil is of use in the early stages, but loses its usefulness later on. Attention should be given to making creosote and other drugs palatable and digestible in the early stages.

My Experience in the Treatment of Pulmonary Tuberculosis by Drugs.—Holland says that creosote and like drugs are useless in arresting tuberculous disease of the lungs and larynx, but are often of service in bronchial catarrh, which is such a troublesome symptom.

The Journal of Tropical Medicine, January, 1900.

Metamorphosis of the Young Form of Filaria Bancrofti in the Body of Culex Ciliaris.—Thomas L. Bancroft describes observations made by him on mosquitoes which were caused to bite a filariated subject. He found that actively moving filariæ were to be seen on the sixteenth or seventeenth day, sometimes not until the twentieth day, and that no further development occurred in them even after a sojourn of sixty days in the insect's thorax. He also made the interesting discovery that the filariæ die after being three or four hours in water, consequently this cannot be the medium through which they reach the human subject. Both of these findings are at variance with those of Manson.

On Tropical Anæmia, and its Relations to the Latent and to the Manifest Forms of Malarial Infection.—In an article with this title, concluded in this number, Albert Plehn discusses not only tropical anæmia but also the entire subject of malaria, including blackwater fever. He objects strongly to the withholding of quinine (which he regards as the only specific for malaria) through fear of causing hæmoglobinuria. He also opposes the theory that the sole mode of infection in malaria is transmission through mosquitoes, his opposition being based upon his experience in Kamerun.

A Case of Goundon or Anakhre.—W. Renner describes the case of a man, thirty-nine years old, in whom the first symptoms were noticed in 1882. The affection consists in a swelling the size of a pigeon's egg, lying obliquely along the nasal process of the superior maxilla on either side. It is apparently the same affection as hempuye or dog-nose, described by Chalmers in *The Lancet* of January 6, 1900. See MEDICAL RECORD, vol. lvii., p. 113.

Treatment of a Leper by Subcutaneous Doses of Chaulmoogra Oil.—Tourtoulis Bey treated a leper for five years intermittently with chaulmoogra oil in doses of gtt. xxx.–l. three times a day. The treatment was finally abandoned, as the oil was no longer tolerated by the stomach. Later the oil was given subcutaneously in doses of 5 gm., and improvement set in almost immediately and has continued up to the present time, during a period of five years.

Lightning Stroke.—R. E. Adamson describes the damage done to a house and one of its occupants by a stroke of lightning. The man felt a terrific blow on the knee and fell off his chair unconscious. He was unable to walk for about a week, but eventually recovered.

Tumbe or Kroo Fly.—A. H. Hanley gives the life history of this fly, which is common in some parts of the Niger protectorate.

Pes Gigas.—P. B. Cousland presents a picture of this affection, but gives no history of the case.

Zeitschrift für Krankenpflege, December, 1899.

Mode of Living for Migraine Patients.—August Dobisch states that migraine is most common in persons between fifteen and fifty years of age. In all such patients there exist defects in the osseous system, hereditary taint, or habits which result in defective nasal breathing and catarrh of the mucous membranes. The physician should study the patient's mode of living, in order to determine which of his habits most readily produces an attack. Lymphatic children suffer in later life from migraine. Close questioning often elicits the fact that some irritation of the upper air passages with consequent irritation of the nervous system has caused the attack. The patients should live in a dry climate. Their clothing should protect them against changes of temperature, hence wool is better than linen. The foot-wear requires careful attention. Sweating is to be avoided; moderation is to be exercised in all things, especially in eating and drinking. Hydrotherapy is best used in the form of cold sponging or very brief baths; cold water is to be taken only in small quantities, and never when one is overheated. The nervous system is to be hardened and protected; excess in wine and coitus should be avoided. The treatment of the attack consists in relieving the nasal obstruction with cocaine solution (3.5 per cent.) and the administration of a saline purgative in order to reduce intestinal fermentation.

Pathogenesis and Prophylaxis of Croupous Pneumonia.—Hans Brunner mentions March, April, August, and September as the four months which are of most importance in their relation to the disease. The characteristics of each, with its temperature changes, winds, sunlight, etc., are given at length. A fall in the pressure of the air exposes the human organism to danger; in the winter it induces perspiration, in the summer a chilling. Individual calling also plays an important rôle; under this heading are mentioned trauma, exertion, marked mental excitement, chilling, and tiring of the body, with sweating and psychical depression. Under the head of prophylaxis, the author says that exertion, sweating, and chilling are to be guarded against at all seasons, especially, however, in the spring. Sudden and extreme climatic changes are extremely dangerous. A stable, relatively moist season is preferable to a changeable one. These changes are especially dangerous to old pneumonia patients, and to those suffering from influenza or bronchitis, or weakened by disease.

Meditsinskoe Obozrenie, January, 1900.

The Diagnosis, Symptoms, and Treatment of Hydro-Pneumothorax.—Ts. I. Shabad presents a study based upon the reports of seven cases, in which he formulates the following conclusions: (1) Hydro- or pyo-pneumothorax may be diagnosed with certainty by means of the *x*-rays. (2) In left-sided hydro-pneumothorax, as in simple pneumothorax, the heart is usually displaced as far as the right mammillary line; when the right side is affected the heart is found in the axillary line on the left side. (3) In left-sided disease a metallic sound is sometimes heard in the left side of the chest synchronous with the cardiac pulsations and the respiration. (4) The patients themselves can feel the movement of the fluid in the chest, and this may be a valuable early symptom. (5) In tuberculous cases with extensive serous or purulent exudations, thoracocentesis with evacuation of the pleural cavity is indicated. In cases of purulent exudation when the pulmonary opening has closed, incision or resection of a rib is necessary. (6) In cases in which life is imperilled, the pulmonary opening not being closed, a drainage tube should be left *in situ* for a time. (7) In many cases of empyema thorough washing out of the cavity may take the place of resection of the rib, but in this case pleural adhesion occurs. (8) Even in cases of pyo-pneumothorax washing out of the cavity may be a good palliative measure.

Gastrostomy by Marwedel's Method.—A. Th. Kablukoff reports two cases of impassable cancerous stricture of the œsophagus in which he made a gastric fistula after Marwedel's method. In this an incision is made in the linea alba from the sternum to the umbilicus, and the abdominal wall is divided layer by layer until the peritoneal cavity is opened. The stomach is drawn to the opening, and two sutures are inserted into but not through the anterior wall of the organ. Then the stomach wall is sutured to the sides of the abdominal incision for a distance of 7–8 cm., and the remaining portion of the incision is closed. An incision, 5–6 cm. long, is now made through the serous and muscular coats of the stomach. In the lowest corner of the mucous tunic a small opening is made through which a drainage tube the size of a lead pencil is passed into the cavity of the stomach. The outer portion of the tube is laid along the bottom of the stomach wound and the muscular and serous layers are stitched over it. Thus is formed a canal 5 or 6 cm. long in the substance of the wall of the stomach. If necessary food can be introduced at once while the patient is on the operating-table.

A Case of Imperforate Vagina.—S. I. Bubnoff reports the case of a woman nineteen years old, who had been married four months. She had never menstruated and coitus was found to be impossible. Examination showed the vagina occluded by a tough membrane bulging outward and fluctuating. On palpation of the abdomen a tense and elastic tumor was felt in the median line reaching over a little to the left. This was about the size of a new-born child's head, and to the left of this was another tumor the size of a hen's egg, of a rather soft consistence and painful on pressure. A diagnosis was made of imperforate hymen with retained menses and resultant hæmato-colpometra and left hæmatosalpinx. This diagnosis was confirmed at the operation, the results of which were so successful that the patient gave birth to a healthy girl a year and a half later.

Late Spontaneous Hemorrhage from the Umbilicus in the New-Born.—J. M. Lvoff reports two cases of umbilical hemorrhage, one on the tenth and the other on the thirteenth day of life. The bleeding in this affection occurs at the end of the first or in the course of the second week, after the stump of the cord has fallen, and is a general oozing from the surface of the umbilical wound rather than a hemorrhage from the umbilical vessels. Hereditary syphilis and hæmophilia are, in the author's belief, the main etiological factors. Applications of styptic cotton or of gypsum usually suffice to still the bleeding, but if this persists a needle may be passed beneath the bleeding surface and vessels constricted by a thread wound round the base.

Castration in a Case of Imperforate Vagina and Rudimentary Uterus.—A. Eberlin and S. Maloletkoff report the case of a woman aged twenty-three years, in whom the following developmental defects were found in the genitalia: The external sexual organs were imperfectly developed; the vagina was completely wanting; there was a uterus rudimentarius solidus unicornis; the adnexa on the left side were absent, but were normally developed on the right side. There was cystic degeneration of the right ovary. The authors have found twenty similar cases of defective uterus and vagina in which operation was performed, and in all but two with success. In five of these cases the adnexa were absent on one side, and that always the left side.

Cases of Ptomain Paralysis.—P. A. Preobrazhenski reports two cases, in a woman aged forty years and her son aged fifteen, of paralysis resulting from auto-intoxication. The chief points of interest were the absence of any prodromes; the apyretic course of the disease; the involvement, in greater or lesser degree, of all or nearly all the voluntary muscles; the greater affection of the muscles of the upper part of the body as compared with those of the lower extremities; the entire absence of any sensory disturbances, vesical or rectal involvement, or psychic disorders; the participation in the paralysis of the vasomotors of the face.

Contribution to the Pathology of the Lower Part of the Spinal Cord.—L. S. Minor reports six cases of traumatic lesions of the lower portion of the spine, usually from falls, in all of which, the sensory, electromuscular, and trophic disturbances were most pronounced and most persistent in the parts supplied by the peroneal nerve. He concludes that in these cases there was a special, purely anatomical lesion of the origin and roots of the peroneal nerves of which the paralysis of the parts was the expression.

Intramuscular Injections of Quinine.—Alexander Ivanoff says it is possible to avoid all the accidents which may follow the subcutaneous injection of quinine by making the injections into the muscular tissue. For this purpose he used a solution of bimuriate of quinine in distilled water (1 : 4), freshly prepared for each injection. The amount injected is 2 gm., the amount of the drug being therefore 0.5 gm. The injections are almost painless, and in more than twenty-five cases in which the author resorted to this method he saw no untoward results at all.

A Case of Interstitial Pregnancy.—V. Stezhenski reports a case of this rare condition occurring in a woman twenty-five years old who had had one normal labor. The fœtus, of about the third month, was removed by operation and the woman made a good recovery. As to the rarity of this condition the author quotes Rosenthal, who collected thirteen hundred and twenty-four cases of ectopic gestation, among which were only forty of interstitial pregnancy.

Tumors.—P. Tikhoff presents an elaborate statistical study of tumors, the chief conclusions from which are that the influence of sex in the predisposition to new growths is not apparent, that cancer occupies an important if not the chief place among tumors as regards frequency of occurrence, and that the extremities are relatively infrequently the seat of neoplasms.

Practical Observations on Antisepsis in New-Born and Nursing Children.—A. N. Ustinoff describes and pictures several forms of apparatus for the disinfection and sterilization of napkins and other articles used in the toilet of infants.

Correspondence.

THE MEDICAL ASPECTS OF THE SOUTH AFRICAN WAR.

(From our Special Correspondent.)

I am thankful that it is only the medical aspects of the war of which I am asked—and, for that matter, am competent—to send an account. For the historic and strategic aspects require great knowledge and great tact in any writer who may try to place them clearly and succinctly before his readers. Writing as I do on the morning of January 24th, when all England is holding breath in expectation of news concerning Sir Redvers Buller's relieving column, now describing a semicircle in the direction of Ladysmith, it is sufficient to say that on the issue of the next few hours hangs largely the fate of the war. I do not mean that England will give up the struggle if she meets with another rebuff; but that a victory now will go far toward redeeming past losses. Further prophecy I will not indulge in, particularly as by the time that this letter reaches you the telegraph will have told you so much more than I now know.

General Hospitals.—The first two general hospitals at Wynberg having rapidly received their complement after the reverse at Magersfontein and Colenso, a third general hospital capable of accommodating five hundred or six hundred patients was set up at Rondebosch, a beautiful high-lying spot between Wynberg and Cape Town, while a fourth was established at De Aar, the important junction three hundred miles or so northeast of Cape Town, whence the railway branches east into the Orange Free State, and northwest to Kimberley. There is a hospital at Pietermaritzburg, which will now hold five hundred or six hundred patients. These five hospitals will give care to at least twenty-five hundred medical and surgical cases, and they will, it is hoped, prove equivalent to the demand, supplemented as they are by several smaller institutions. The transport and hospital ships plying between Cape Town and Southampton have already begun to bring back to England regular relays of sick and wounded who are able to travel, and with such abstraction, amounting now to five hundred at least, from the totals of the convalescents the accommodation provided by the general hospitals should be sufficient. In Great Britain at various hospitals and institutions five hundred and seventy beds have been placed at the disposal of the government for the reception of these convalescents, while similar offers are coming in fast. The Herbert Hospital and Netley Hospital will accommodate as many more, so that the after-care of the wounded need not be a source of much anxiety to the nation. In addition, many noblemen and gentlemen are offering their country houses to be used as convalescent homes, guaranteeing the expense of support as well as giving the shelter.

A Half-Way Treatment for the Convalescents.—In view of the fact that a great many of the sick and wounded who have so far arrived home again have been practically cured, and are ready to return to the front, two proposals have been made: (1) That convalescent homes should be established in South Africa; and (2) that such homes should be established in the middle of the return journey, viz., in Madeira and the Canary Isles. The first plan is not indorsed by thinking people. There may at any time be great strain on the resources of Cape Town, the population of which has become wellnigh doubled during the last few weeks; the sea voyage has probably counted for much in the excellent plight in which many of the wounded have reached British shores; and, lastly, as the transports must go from England to the Cape carrying stores, furniture of war, reinforcements, and horses, they may as well convey the sick to England, where ample provision for them can be made. But half-way homes at Madeira are an excellent suggestion, to which practical effect may be given. I do not expect, however, that it will.

The Stationary Hospitals and Bearer Companies; the R. A. M. C. Under Fire.—There are, of course, stationary hospitals in Natal, behind General Buller's advancing force, and behind the columns which have proceeded north against the Orange Free State, or to the relief of Kimberley. Those in Natal had their positions at Frere and Estcourt. The stationary hospital at Frere was designed by Major R. Kirkpatrick, R.A.M.C., and is manned by a quartermaster, four members of the Royal Army Medical Corps, and thirty-eight non-commissioned officers, compounders, cooks, etc.; it has also two army nursing-sisters. At the battle of the Tugela River (sometimes called the battle of Colenso) their hospital was moved to Chieveley, and connected with the bearer companies by twelve hundred civilian stretcher-bearers. The bearer companies went quite up to the fighting line, an ambulance train accompanying them so far that it had to be turned back lest it should be hit by a shell. Each bearer company was manned by a surgeon-major, accompanied by three junior medical officers, fifty non-commissioned officers and military bearers, five hundred civilian bearers, ten ambulance wagons, and a general service wagon. When the battle commenced stretcher squads picked up the wounded from just behind the fighting line, and bore them to a collecting-station. Here the wounded were sorted and carried by stretchers and ambulance wagons to the dressing-tents. There they received first aid, and were sorted in cacordance with their injuries, before being conveyed to the stationary field hospital where the operating-tables were set up. The scene in the operative tents at the station field hospitals beggars detailed description. From 3 A.M. until late at night the operators were hard at work, and altogether eight hundred patients passed under special treatment during the time mentioned.

OUR LONDON LETTER.

(From our Special Correspondent.)

WAR — INFLUENZA — WATER SUPPLY — PATHOLOGICAL SOCIETY; THROMBOSIS, CANCER, PNEUMOCOCCUS — GYNÆCOLOGICAL ADDRESS — APPENDICITIS — SIR M. FOSTER FOR M. P. — SIR H. BEEVOR — LOCAL GOVERNMENT BOARD APPOINTMENTS — DUBLIN MORTALITY — RECENT DEATHS.

LONDON, January 26, 1900.

THE war is almost the sole subject of interest, but in this moment of tension I must not write about it. You will have all the general news from other sources. But I cannot forbear saying that amid all the criminal blundering and neglect of the War Office to which the attention of Parliament is about to be devoted, the conflict in South Africa has shown one bright spot, viz., the medical department, the service which the "combatant" influence has done its best to cripple. The insane jealousy of all "civilians" of the commander-in-chief was always directed to snubbing "mere doctors," and has now reaped its reward. The colonial horsemen he declined on the outbreak of the war, and who were just the men for the work, are at once engaged on the arrival of Lords Roberts and Kitchener.

The wave of influenza is receding here, though not yet in the northern towns. The deaths from the epidemic last week in London fell to two hundred and eight. The rate per thousand for the last four weeks has been 35.2, 37.1, 33.3, and 26.9. In the thirty-three great towns the rate averaged 24.9 as against 29.1 the previous week. In twenty-three of these towns there was an absolute decrease. The highest rate was at Nottingham—32.2—but even that was better than the 44.9 of the previous week, which was the highest rate recorded anywhere during the epidemic. It is thought that though there is an extension of the epidemic northward, its virulence is declining.

The royal commission on the water supply of London issues its final report this week. Their opinion is against permitting the county council to buy up the companies. Further, they say that the cost of bringing water from Wales would be double that required to make the present source adequate until 1941. This plan would cost twenty-eight or twenty-nine millions sterling, to meet which a three-per-cent. stock is recommended secured on the water charges. The commissioners favor the establishment of a new permanent board to control the whole supply, and the proceeding of which board should periodically be brought automatically under the notice of Parliament.

At the last meeting of the Pathological Society Mr. W. Pakes read a description of a case of thrombosis of the right and left iliac and femoral veins, in which he found post mortem bacillus proteus vulgaris. Although this organism is often associated with decomposition after death, he did not think that would explain this case, as the clot contained considerable numbers and there was no obvious decomposition.

Dr. T. G. Stevens gave an account of a thrombosed ovarian vein following hysterectomy. Cultures made with every precaution against contamination showed colonies of bacillus coli communis and bacillus pyocyaneus. Considering our scanty knowledge of the cause of thrombosis it seems desirable that further bacteriological examinations should be made.

Mr. Shattock showed a specimen of spontaneous carcinoma of the uterus of a rabbit, a disease the existence of which seems to have been unknown to many pathologists. It was of interest in reference to Dr. Lack's experiment last year, the result of which is regarded generally as a coincidence, a view taken by Mr. Shattock on this occasion and supported by Dr. Coupland and Mr. Ballance, the latter remarking on the frequency with which what in first experiments may be taken for law turns out to be only an incident.

Dr. Auld read a paper giving an account of some two hundred experiments, extending over two years, with toxins of pneumococcus. Rabbits were principally used. In these an increased sensitiveness to the pneumococcus was produced by inoculation of the toxins, and that under all circumstances of dosage. Attempts to immunize in this way, therefore, seem contraindicated. This result harmonizes to some extent with what has been found in plague and some other toxins. It was suggested that the intracellular bodies of the micro-organisms might be more suitably immunizing agents, as Foà and Scabia had found a watery glycerin extract of the dead bodies better than the diluted virus itself. The occurrence of paralysis of the fore-legs in two cases was notable as not previously observed, and may indicate that the poison has an affinity for the nerves and centres supplying these parts. Dr. Auld had been helped by Dr. Cartwright Wood, and in reply to questions said the hypersensitiveness to the toxins was certainly remarkable, but had also been met with in plague, in diphtheria in guinea-pigs, and he believed with tuberculin under certain circumstances.

At the annual meeting of the Gynæcological Society Dr. W. J. Smyly was elected president for the ensuing year, and the retiring president, Dr. Macnaughton-Jones, delivered a valedictory address on "The Correlation between Sexual Function and Insanity and Crime in Women." From a careful study of the questions involved he concludes: (1) That the correlation of insanity and disordered sexual function arising from affections of the generative organs is a factor to be seriously considered in the treatment of the mentally afflicted. (2) When there is ground to suspect disease of the uterus or adnexa which might aggravate the mental affection, a careful examination should be made, anæsthesia being employed if necessary. (3) In the investigation of crime committed by women during the menopause or while the menstrual function is either active or suppressed, due weight ought to be attached to the influence on the mind of the woman of the irregularity or abeyance, and her previous history and temperament. (4) The special dangers of the climacteric ought to be considered. (5) After operations on the female generative organs there is greater predisposition to mental disturbance than after other procedures. (6) Women who have been insane are predisposed to relapse by the development of disease in or operations on their generative organs. Taking these conditions into consideration it seems that close supervision and care are required to anticipate insane impulses in patients who have shown any symptoms of mental instability.

Dr. Macnaughton-Jones must feel well rewarded for his labors as president by the very hearty vote of thanks which was accorded him by acclamation on the motion of Dr. Routh, seconded by Dr. Smyly, and supported by Mr. Stanmore Bishop. The speeches of these gentlemen were enthusiastic, and their warmth found an echo throughout the audience.

On Monday the Medical Society was regaled with a paper by Mr. Lockwood on that continually recurring subject, appendicitis. The paper elicited a discussion, which was adjourned to February 24th. Mr. Lockwood illustrated by a number of lantern slides the appearances described. By means of photographs of sections he traced the spread of infection through the lymphatics to the peritoneum. He described the varieties of the affection from mild appendicular colic to catarrh, stenosis, ulceration, and gangrene. The conditions appeared to him to be unfavorable to a process of natural cure. Fecal concretions are always associated with ulceration, and Mr. Lockwood's specimens seem to show that they are due to bacteria—a point not previously noticed. Bacterial accumulation in the appendix seems the cause of both the ulceration and concretion.

Dr. Allchin admitted that much progress had been made in our knowledge of this disease, but he defended medical treatment in a considerable number of cases, and thought surgical intervention only called for when pus had been formed. In the ordinary run of cases met with in the medical wards the symptoms usually subsided in about two weeks, and the patients seemed practically cured. These were the cases in which medical treatment was useful, and he regarded small doses of opium, supplemented sometimes by belladonna, as a valuable remedy. As to prognosis he attached much importance to an increase in the rapidity of the pulse. Of course in fulminant and acute cases, and when pus was diagnosed, surgical intervention must not be delayed. Relapsing cases were difficult, but many would be benefited by rest and treatment.

Mr. Barker considered the infection of the lymphatics as demonstrated in the paper and illustrations. Some very difficult cases could be explained in this way, *e.g.*, those in which inflammation occurred at a distance, including subphrenic abscess. He agreed that opium was useful. He insisted on the bactericidal power of the peritoneum, and was not in the habit of washing out the abdominal cavity. Even in widespread suppuration he limited his intervention to the smallest possible area of peritoneum.

Dr. F. Smith remarked that in a considerable number of ulcerated and some gangrenous cases there was no previous history of pain, a fact also observed in many cases of gastric ulcer. He said that even in the post-mortem room it is practically impossible to cleanse the peritoneum, so that he doubted if the surgeon could effect it on the operating-table. From a large number of autopsies he was led to conclude that the most common position for the appendix was behind the cæcum or the ascending colon—so that the surgeon should make an incision which would give access to that region. He regarded rapidity of the pulse and the occurrence of night sweats as reliable indications.

Sir Michael Foster is a candidate for the representation of the London University in succession to Sir John Lubbock, who has been raised to the peerage.

Sir Hugh R. Beevor, Bart., M.D., etc., has been appointed representative of the Society of Apothecaries in the General Medical Council, vice Mr. Brudenell-Carter.

Mr. W. H. Power, as was generally anticipated, is promoted to the principal medical officership of the Local Government Board, in succession to the late Sir R. Thorne Thorne. Dr. Franklin Parsons and Dr. Bruce Low become assistant medical officers.

The committee of inquiry into the excessive death rate of Dublin, which I told you the lord-lieutenant contemplated, has been appointed. It was time, for the registrar-general reports a rate of 49.4 per 1,000 with further increase in deaths from zymotic diseases.

Dr. Grimshaw, registrar-general for Ireland, and ex-president of the Dublin College of Physicians, died on Tuesday.

Dr. John Gorham, who died last month, aged eighty-five years, contributed various medical papers to the journals, but devoted his work chiefly to science, especially optics and mineralogy. He was a fellow of the Botanical and other scientific societies and the contributor of many papers.

Another aged and retired veteran who died lately was Dr. Humphry Minchin, who took his diplomas in 1838 and 1840. He was for some time professor of botany at the Dublin College of Surgeons, and many years treasurer of the Irish Medical Association.

Among other recent deaths are those of Inspector-General E. T. Mortimer, lately in charge of Haslar Hospital. He had a very distinguished career in the navy, and retired in 1894, aged sixty-six years.

Dr. Robert Collum died at the age of eighty-six years. He served in the East India Company, and after his retirement took a prominent part in the Society of Members of the College of Surgeons.

Dr. O'Sullivan, professor of surgery, Queens College, Cork, died aged sixty-four years.

Dr. Samuel R. Mason died suddenly on the eighth inst. He was professor of midwifery R.C.S.I., and had been master of the Coombe Lying-in Hospital. He was only forty-seven years old, and his aged father (born in 1817), who survives him, was joint founder with Dr. Ledwich of the Ledwich School of Medicine, Dublin.

Dr. C. P. Walker, R.A.M.C., died on the fifth inst., at Ladysmith, from dysentery. He was in the front at Dundee and Elandslaagte.

FORM OF LEGISLATION WHICH WILL ENABLE CITIES, TOWNS, AND VILLAGES IN THE STATE OF NEW YORK TO ESTABLISH HOSPITALS FOR THE TREATMENT OF TUBERCULOSIS.

To the Editor of the Medical Record.

Sir: The proposition to establish local hospitals for "consumptives" is based on the following consideration: 1. Consumptives must be under strict medical supervision in order that rules relating to personal hygiene may be rigidly enforced. 2. With the poor this supervision can be properly enforced only in a hospital. 3. As these hospitals are for the poor they should be located as nearly as possible to their homes. 4. It now appears that if these hospitals are well managed, though located near any village or city on a dry and protected place, patients recover quite as rapidly as in a sanatorium on a distant mountain. 5. The local hospital is a centre of instruction to the neighboring community of the utmost value, for experience proves that the people quickly learn from those who are being treated in the hospital how to prevent the spread of the germs of tuberculosis, and strictly follow the rules therein enforced. 6. The cures effected in the local hospital are more likely to be permanent than those obtained in hospitals under different climatic conditions. 7. Vast numbers of sick poor will cherfully enter the local hospital, where they can be near their homes, who would not go to a distant sanatorium.

Fortunately we have in this State a well-organized system of public-health administration, which can be made immediately available in the organization and management of local hospitals in every community. The public-health law requires the creation of boards of health in every city, town, and village in the State. These boards are composed of the best citizens in each locality, and as a rule they choose thoroughly competent medical men as health officers. Finally, they are under the general jurisdiction of the State board of health.

The question has arisen, What legislation would be necessary to enable local boards of health to establish local hospitals for the treatment of "consumptives" within their respective jurisdictions? The following sections of a bill to accomplish that purpose have been formulated from the "public-health law," and from a "Circular of Information concerning the Measures adopted by the State Board of Health for the Prevention of Tuberculosis in the State of New York." The first four sections are a nearly literal transcript of that circular, and the passage of such a bill by the legislature would simply give legal effect to the rules and regulations of the State board of health, now existing, for the prevention of tuberculosis. These sections of a bill are submitted as suggestions to those engaged in securing legislation for that purpose.

"SECTION 1. The board of health of the State of New York having declared, officially, that the communicability of tuberculosis or consumption has been so thoroughly established, and is now so generally recognized by the medical profession throughout the world, that it has determined to take such active measures as may be consistent and possible for the prevention of the disease among the people of the State, it is hereby made the duty of said board and local boards of health to co-operate, as far as practicable, in the enforcement of the measures provided in this act for the prevention of the spread of tuberculosis.

"SECTION 2. Local health officers hereafter shall register the name, address, sex, and age of every person suffering from tuberculosis within their respective jurisdiction, so far as such information can be obtained, and all physicians shall forward such information to the health officials in the respective jurisdictions in which such cases may occur. This information shall be solely for the use of health officers, and in no case will visits be made to such persons by public officials, nor will any public sanitary surveillance of such patients be assumed, unless the patient resides in a tenement house, boarding house, or hotel, or unless the attending physician requests that an inspection be made of the premises, and in no case where the person resides in a tenement house, boarding-house, or hotel, if the physician requests that no visits be made by inspectors, and is willing himself to deliver circulars of information, or furnish such equivalent information as is required to prevent the extension of the disease to others.

"SECTION 3. When a local health officer obtains knowledge of the existence of cases of pulmonary tuberculosis residing in tenement houses, boarding-houses, or hotels, unless the case has been reported by a physician, and the latter requests that no visits be made, inspectors will visit the premises and family, will leave circulars of information, and instruct the person suffering from consumption, and the family, concerning the measures which should be taken to guard against the spread of the disease; and if it is considered necessary, will make such recommendations for the cleaning or renovation of the apartment as may be required to render it free from infection.

"SECTION 4. In all cases where it comes to the knowledge of a local health officer that premises which have been occupied by consumptives have been vacated by death or removal, he or an inspector will visit the premises, and direct the removal of infected articles, such as carpets, rugs, bedding, etc., for disinfection, and will make such written recommendations to his immediate superior concerning the cleaning and renovation of the apartment as may be required. An order embodying these recommendations will then be issued to the owner of the premises, and compliance with this order will be enforced for sanitary reasons. No other persons than those there residing at the time will be allowed to occupy such apartments until the order of the health officer has been complied with.

"SECTION 5. Whenever any board of health of a city, town, or village shall certify to the State board of health that, as a means of preventing the spread of tuberculosis within its jurisdiction, it is necessary to establish a hospital or hospitals for the treatment of persons suffering from that disease, said State board shall cause an investigation to be made of the conditions alleged to exist, and if it shall appear that there is a necessity for the hospital or hospitals proposed by the local board, the State board shall enter upon its minutes an order directing the establishment of one or more hospitals for the care and treatment of persons suffering from tuberculosis within the jurisdiction of the local board making such application, and shall cause a copy of said order to be forthwith served upon said local board; on the receipt of said order, the local board shall cause its entry upon its minutes, and, as soon as practicable thereafter, shall proceed to establish the required hospital or hospitals, but no site or sites shall be selected, nor buildings erected nor rented for that purpose, without the approval in writing of the State board of health and the State architect. Hospitals established under the provisions of this act shall be under the control of the local board of health having jurisdiction of the district within which it is located, except as hereinafter provided, and shall have power to appoint attending and resident physicians and such officers, nurses, and employees as may be necessary for the proper and economical management of any said hospitals; it shall prescribe the conditions of admission of patients and the rules and regulations governing their management. All expenses incurred in executing the provisions of this section shall be collected and paid as provided in section 30 of the public-health law.

"SECTION 6. Whenever it shall appear to the State board of health that a hospital or hospitals for the care and treatment of tuberculosis can be located more advantageously and managed more economically if one or more towns and the incorporated villages therein unite in one sanitary district, as provided in Section 29 of the public-health law, said State board shall notify the boards of health of the proposed sanitary district of its decision, and the local boards of health shall, on receiving such notification, appoint one of their members to meet representatives of the several boards of health of the proposed sanitary district, at such time and place as the State board shall direct, for the purpose of effecting an organization to supervise the establishment and management of one or more hospitals for the sanitary district thereby created. The action taken by the representatives shall be submitted to their respective boards, and if approved, each board shall appoint one of its members to be a member of a board of managers of the hospital or hospitals to be created, and said board of managers shall forthwith proceed to establish the hospital or hospitals authorized by the joint action of the several boards of health, either by leasing existing buildings or by the erection of new structures. All expenses incurred in leasing or erecting buildings, and in the furnishing and management of the hospital, shall be a per-capita charge upon the people of each town and municipality of the sanitary district, to be audited, levied, collected, and paid in the same manner as the other charges of, or upon, the town or municipality are audited, levied, collected, and paid.

"SECTION 7. The board of managers hereby created for the hospital of the sanitary district shall have the same powers to lease existing buildings, or to select a site and erect buildings, for the proposed hospital, and to select a visiting and resident staff of physicians, and to appoint officers, and fix their pay, and make rules governing the admission of patients, as local boards of health, as provided in section 5 of this act, and it shall annually, on or before October 1st of each year, make an itemized report of all expenditures for the preceding year, together with estimates of necessary expenditures for the succeeding year; also statistics of the patients, and the results of treatment; with such suggestions as the board may deem useful. A copy of said report shall be furnished to each of the several boards of health in the sanitary district."

STEPHEN SMITH, M.D.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 1, 1900.

William H. Thomson, M.D., President.

Amendment of Federal Tax on Legacies to Charitable and Educational Institutions.—A petition, praying for the amendment of the federal tax law regarding legacies to charitable and educational institutions, was presented to the Academy for its indorsement, on the ground that the tax was excessive. It was stated, in the discussion, that the tax, according to the present law, amounted to one-tenth of the whole amount of the legacy. On motion of Dr. Leonard Weber, the Academy gave its official indorsement to this petition to Congress.

Antivivisection Bill.—The Academy also formally indorsed the opposition to Senator Gallinger's antivivisection bill.

Causes of Failure of Compensation in Heart Disease.—Dr. Morris Manges presented a communication on this subject. He stated that in one hundred and two cases studied by Romberg, the average duration of compensation had been found to be seven years. To the myocardium one must look for compensation, and what had been aptly called by Romberg "decompensation." It was now quite generally accepted that fatty degeneration played only a minor part in the production of decompensation. Even undue distention of the heart might be successfully met by a sound heart muscle, but excessive tension of sufficient duration to cause exhaustion of the heart muscle was most dangerous. It should be remembered that the rate of normal muscular fatigue varied with the individual. It had been shown by Theodore Schott that the normal heart could successfully cope with acute dilatation. Littell claimed that in hypertrophy the interstitial tissue increased as well as the muscular fibres. In acute infectious diseases it was not improbable that acute interstitial changes resulted directly in an increase of the connective tissue. According to Deyo there might be a myofibrosis affecting the whole heart, but this view had not been sustained by later observers. The nervous system had also been found at fault, changes having been discovered in the heart ganglia. Hearts which have been attacked by organic valvular disease from any cause no longer had a normal myocardium, since the latter had been involved in foci, or diffusely. While a hypertrophied heart was more liable to arteriosclerosis of the coronaries, and to chronic myocarditis, yet proper care of the general nutrition and proper adjustment of the work of the heart might postpone decompensation indefinitely. From the clinical standpoint it could be said that failure of compensation of the heart was not a clinical entity. Changes in the heart wall leading to failure of compensation might result (1) from failure of the general nutrition of the body; (2) from disturbance of the local nutrition of the heart; (3) from increased work of the heart; (4) from functional cardiac disorders. Gout, rheumatism, and various other constitutional disorders were also potent factors. More rapid in action were such acute infections as acute rheumatism, diphtheria, scarlet fever, typhoid fever, pneumonia, influenza, and sepsis. Chronic arteriosclerosis was by far the most common of the causes affecting local nutrition of the heart. Hearts with valvular disease and hypertrophy were specially liable to these disturbances of nutrition. The danger to the heart of prolonged and violent physical exercise was now generally recognized. In this connection it might be mentioned that the muscular effort associated with parturition would often seriously damage the heart already enfeebled by valvulitis. Fright or extreme and prolonged worry must be included among the causes. A final group could be made of those cases in which much mischief was caused by the irrational and unnecessary use of drugs commonly known as cardiac tonics. The popular abuse of coal-tar products and of the thyroid extract came under this head, as did also an unwise use of cures for the reduction of obesity.

Aortic Valvulitis and Aortitis.—Dr. Frank Jackson, in this paper, confined his attention chiefly to the mechanical results of chronic inflammation of the aortic valves. Chronic inflammation of the aortic valves, he said, resulted most commonly from rheumatism, gout, syphilis, chronic alcoholic poisoning, and excessive and continued muscular strain. The result of chronic aortic valvulitis might be primary or secondary. The primary result would be thickening and deformity, or perhaps rupture of segments of the valve. When there was much deformity of the aortic valve, hypertrophy, dilatation, and irregular action of the heart resulted. While pure aortic stenosis was undoubtedly occasionally found, the condition most commonly passing under that name was one in which a thickened or stiffened valve was associated with a systolic murmur heard over the base of the heart without any true stenosis being present. When the valves were greatly deformed, one found aortic regurgitation and marked hypertrophy and dilatation of the heart. Aortic insufficiency was as common as aortic stenosis was uncommon. The causes of aortic insufficiency were: (1) Congenital malformation of the valves; (2) traumatic rupture of one or more valves, (3) acute endocarditis; (4) chronic endocarditis, the result of rheumatism, strain, syphilis, gout, or chronic alcoholic poisoning. It was so commonly found in athletes that it had been termed "the athlete's heart." The effect of the regurgitation of the blood during diastole might be very considerable. In many of these cases the patient complained chiefly of a tumultuous action of the heart, and more or less dyspnœa on exertion. In some instances, with moderate leakage of the valves, compensation might be maintained for years, and the individual might never know that there was anything wrong with his heart. Such cases usually followed an endocarditis, and were not a part of a general arteriosclerosis. Sudden death was more frequent in these cases than in any other form of valvular disease, though the majority of these persons died feeble and emaciated, often of some intercurrent disease. The physical signs were the murmur, the enlargement of the heart, the action of this organ, and the condition of the arteries. The murmur itself must not be considered as evidence of heart disease. Likewise, the absence of a murmur, when there were other symptoms of cardiac disease, should not be regarded as evidence that there is no valvulitis. A murmur might, and frequently did, appear or disappear repeatedly. While such murmurs were most commonly heard in connection with functional disorder of the heart, they were also noted in conjunction with organic disease of the heart. Some murmurs were audible to the ear and not with the stethoscope, and the reverse of this was also true. He had no explanation to offer for this peculiar phenomenon. Again, murmurs did not always confine themselves to the classical situation. The murmur of aortic regurgitation particularly was often heard only over the ensiform cartilage; less frequently the murmur produced by this lesion was audible only at the apex of the heart. The cardiac murmur should be looked upon only as corroborative evidence of the existence of heart disease, the diagnosis not being made on the presence of a murmur only, but upon the size of the heart, the character of its action, the condition of its muscle, and the concomitant symptoms. A tumultuous action of the heart was sometimes the result of a neurosis, and an apparent enlargement downward in some instances was to be explained by a long, narrow thorax, with a thin muscular covering. The condition of the arteries must be noted, both as regards the presence or absence of arteriosclerosis, and also as to the tension. In aortic regurgitation the dyspnœa was not very severe so long as the mitral valve was competent. Painful sensations were especially common in this form of valvulitis, and least common in mitral regurgitation. The pain was usually substernal and was developed on exertion, though occasionally it was present when the person was at rest.

Chronic Aortitis.—Chronic inflammation of the aorta was usually associated with a similar condition of the aortic valves. The causes were practically the same as those of aortic valvulitis. The symptoms depended upon the nature of the changes. If the aorta was roughened by atheroma, there might be a systolic murmur unassociated with the change in the size or action of the heart. A thinning of the coats of the aorta might result in the formation of an aneurismal sac, and this, in turn, might give rise directly to no symptoms further than those resulting from pressure, and a simulation of other conditions.

Recent Methods of Treatment by Baths and Exercises.—DR. THOMAS E. SATTERTHWAITE described in this paper the methods employed by him in the past two years. He stated that the exercises consisted of flexion, extension, adduction, abduction, and rotation of the limbs, neck, and trunk by the patient, while the operator resisted. Between each single movement there was an intermission. Certain respiratory passive movements he had also found exceedingly useful. For patients in bed, they were instructed to lie on the back while the operator passed his hands under the chest and raised it slowly without lifting the person actually from the bed. This movement was specially adapted to obese patients, or to cases of cardiac dropsy. Each respiratory movement was in the direction of artificial respiration, and should be repeated from one to five times a minute. For stronger patients, they were instructed to sit on a stool while the operator, standing behind, grasped the axillæ, the arms being raised, and raised the patient upward, at the same time bending him backward. The various exercises should be so interwoven as to give a pleasing variety. The séance at first should not last more than fifteen minutes. Slight albuminuria, slight glycosuria, and slight dropsy did not absolutely contraindicate the use of the baths. After the first week of the baths it was his custom to begin to carbonate them. The immersion should not be less than four minutes nor more than fourteen minutes. As a rule, the temperature at first should be 98° F., and an effort should be made usually to reduce the temperature gradually, but not more than one degree each time. A bath should never be made of such a temperature that the patient, on immersion, feels a sensation of chilliness. Intermittent baths had been found more useful than consecutive ones. In neurotic cases it was not advisable to use the more concentrated salts. Baths should not be used in cases of Bright's disease in which the parenchyma of the kidney was extensively involved. Many cases of arteriosclerosis were not benefited. In general, cardiac dropsy, if extensive and advanced, was not likely to be benefited by such treatment. The baths and exercises were applicable, in his experience, to about eighty per cent. of the cases of cardiac disease with broken compensation.

DR. LEONARD WEBER said that as long as the myocardium was not diseased, simple attenuation and hypertrophy would not shorten life. The case was very different when the myocardium was diseased. In cases of acute rheumatic endocarditis the myocardium was the seat of an œdematous infiltration, which was, as a rule, temporary. With reference to the Nauheim treatment, he advised against neurasthenics with cardiac neuroses being sent there, and likewise rheumatic subjects, because of the great dampness of that place. He called attention to the fact that physicians when sending their patients to such bath establishments were commonly negligent about sending with them an accurate history, with suggestions as to the treatment. It was very important that the baths should not be given too frequently or be of long duration.

DR. WILLIAM H. THOMSON explained that his reason for arranging for this discussion on cardiac disease, occupying two meetings of the Academy, was to direct attention to cardiac conditions that might necessarily have no relation to cardiac murmurs. The discussion of this evening had shown very clearly that heart diseases were characterized by a great complexity of symptoms, and Dr. Satterthwaite had insisted upon leaving the heart alone and directing attention to the betterment of the circulation through the muscles, and to improving the functions of the various organs of the body. Personally he believed one of the greatest mistakes in cardiac therapeutics was the placing any reliance for permanent benefit on such drugs as digitalis, strophanthus, strychnine, caffeine, nitroglycerin, sparteine, etc. These were all nervines, and no nervine could have any effect on the nutrition; they served only to stimulate function. Undoubtedly they were useful to combat temporary danger, or as adjuvants to what he would call the real remedies. Throughout the whole animal kingdom muscular power was in direct proportion to the amount of oxygen used. In chronic atony of the stomach and intestine; in chronic atony of the bladder, in chronic bronchitis and emphysema, there was nothing like an abundant supply of fresh air, and he believed the gynæcologist would have to go out of business if all women worked in the open air. In chronic cardiac disease he always made it a point to give iron because this was the remedy that helped us to breathe. The mineral ingredients of the Kissingen water and of the Saratoga Vichy water were the same as those of the human blood. A full dose of either of these waters, therefore, amounted to a full dose of an excess of what was already in the system; there was no foreign substance to eliminate. In heart disease he made use of two drugs which he could not do without, although he was unable to understand how they acted. One of these was sodium iodide, which he gave continuously in doses of gr. v.; the other was calomel, which he gave intermittently.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, January 29, 1900.

GEORGE B. FOWLER, M.D., PRESIDENT.

How the Milk Supply of New York May be Improved.—DR. HENRY DWIGHT CHAPIN opened the discussion with a communication on this subject (see page 230).

The Work of the United States Department of Agriculture in Connection with the Production and Handling of Milk.—MAJOR HENRY E. ALVORD, chief of the dairy division, Bureau of Animal Industry, Washington, D. C., took up this topic. He said that the chief object of the department was to improve and help the farmer, but the department also conducted a large experimental station. The Bureau of Animal

Industry, he said, had been chiefly in the hands of veterinarians, and had in years past devoted itself largely to veterinary matters. Later, it had been engaged a good deal in the inspection of meats, and since July 1, 1895, there had been the dairy division, under his care. The function of this division was to acquire and disseminate information useful to dairymen. Heretofore there had been but little surplus dairy products in this country, with the exception of cheese, but it was probable that in the near future there would be a greater surplus, and hence the division had been looking for foreign markets for such products. The division had been engaged in a series of experimental exports of dairy products. With this same end in view it was the intention to make a good display of such products by the government at the Paris Exposition this year.

Number of Cows in the United States.—The first attempt to count the cows of the United States was made in 1840, and although this attempt had been repeated at each decennial census, there had been no pretence that even an approximate count of the cows in this country had ever been made. A special effort was to be made in connection with the next census to obtain a fairly accurate count. It was probable that there were from five to five and a half millions of cows kept in this country for the purpose of producing milk for food, or about one cow to every fourteen persons of all ages. But every cow in this country does not give more than four quarts of milk daily, so that the supply is only about half a pint a day for each person in the United States—not a very ample supply.

Milk as a Food.—The speaker said that the value of milk as food was not appreciated either by the producer or by the consumer. Milk was certainly better handled now than even a few years ago, and its transportation and distribution were also better. Moreover, the quality of the milk was better, as shown by the proportion of butter fat and total solids, and also as regards its freedom from bacterial contamination. This improvement he attributed less to legislation than to the individual enterprise of certain dairymen and companies. He was of the opinion that the milk supply was a great deal better than it was regarded by many people. There had been much unnecessary alarm over the possible danger of milk as a food. That milk was sometimes harmful could certainly not be disputed, but the number of such well-authenticated cases was proportionately very small. The standard of three per cent. of butter fat for food was enough for all practical purposes, as milk containing four per cent. or more of butter fat frequently had to be reduced in order to make it acceptable to the human stomach. A moderately low percentage of butter fat was not really harmful, except in a commercial sense. From a careful survey of the milk supply of the United States as a whole, the speaker said that he felt entirely safe in saying that the actual presence of disease germs in such milk supply was very rare, and the cases of actual injury from these germs was rarer still. The great mass of evidence on this subject was negative, and in favor of milk rather than against it. Any one could satisfy himself of this by personal search of the official records.

Sterilization and Pasteurization Condemned.—All were agreed as to the undesirability of adding preservatives to milk, for they were simply a premium on carelessness, filth, and dishonesty. He felt strongly disposed to make the same statement regarding both sterilization and pasteurization. These methods should be employed only under certain circumstances, and by no means as the rule. Condensed milk was much less digestible than good natural milk; there should be further and more scientific research regarding the digestibility both of condensed milk and of milk that has been sterilized or pasteurized. He would, at the present time, advocate pure natural milk over all other preparations of milk as food.

Food Value of Skimmed Milk.—Concerning the food value of skimmed milk the speaker remarked that one hundred pounds of skimmed milk contained more valuable food for the human being than one hundred pounds of whole milk. Butter fat had its function in the human economy, but it was not the valuable portion of the milk as a food.

New York Health Board Arraigned.—With the greatest energy possible the speaker characterized the attitude of this city on this skimmed-milk question. He declared that there was no difficulty in regulating the sale of skimmed milk, if it was only energetically undertaken. Of course, prohibition was easier, but the attitude of New York City on this question was that of a lazy man. There was no article of animal food produced on this continent which could compare in usefulness, and pound for pound when bought at the market prices, with skimmed milk, and yet the sale of this article was prohibited in New York City simply because the city authorities had not felt like exerting themselves sufficiently to regulate properly this most desirable traffic. Skimmed milk was sold in Boston, and very largely in the Connecticut valley to the milk operatives, and the latter partook very largely of this product, greatly to their advantage. Another great inconsistency on the part of the authorities of New York City was that they freely admitted condensed skimmed milk (condensed milk sold at low prices in the city) but barred out ordinary natural skimmed milk.

Dairy Bacteriology.—PROFESSOR H. W. CONN, of Wesleyan University, Middletown, Conn., discussed this topic. He introduced it by saying that he did not purpose to treat of it from the standpoint of an alarmist, for he was far from being that. If the ordinary sediment from milk was studied under the microscope, it would be found, he said, to consist of sticks, insects' legs and wings, of hay, of blood and pus—in fact, almost everything possible in the way of dirt, but, alas! a large part of it was excrement. It had been estimated that New York City consumed at least three hundred pounds of cow's excrement daily. He was glad to say that some of the milk-supply companies were endeavoring to bring about a better condition of things.

The Centrifuge and the Strainer Actually Increase the Number of Bacteria.—The centrifugal machine or the strainer only succeeded in removing the coarser portions of this dirt, and certainly bacterial contamination was not in the least affected by straining or by the action of the centrifugal machine. It was a well-known fact that both these processes really increased the number of bacteria by actual count. This was to be explained by the fact that a large number of bacteria were often confined in masses of dirt, and, as these masses were broken up by the centrifugal machine or by the strainer, the bacteria were distributed throughout the milk.

Number of Bacteria in Milk.—The cow was the great source of bacteria in milk. The number might vary from three or four thousand per cubic centimetre in very good milk up to ten or twenty million per cubic inch. Ordinary city milk contained from three to six million of bacteria per cubic centimetre. The number of bacteria varied with the cleanliness of the dairy, the age of the milk, and the temperature at which it had been kept.

Flavor of Butter due to Bacteria.—The presence of these bacteria had caused the development of the milk industry as it existed in this country. To these bacteria was to be attributed the delicate flavor of good butter. Butter made from cream free from bacteria was tasteless. While this was the kind of butter relished and purchased in Europe, it was not at all marketable in this country. The taste of cheese was also largely dependent upon the presence of bacteria.

Pathogenic Bacteria in Milk.—Only a few of the bacteria found in milk were parasitic, and they were the pathogenic bacteria as distinguished from the nonpathogenic. Fortunately, we could almost count on the fingers of one hand the number of human diseases that could be attributed to the milk supply.

Diseases Attributable to Milk.—These diseases were divisible into three types. The first type came from the cow; the second type came from the secondary contamination, and the third type was the result of poisons produced by the bacteria growing in the milk rather than from bacteria growing in the human organism.

Tuberculosis from Milk.—There was only one disease of any importance that could be traced to the cow herself, *i.e.*, tuberculosis. His own opinion was that the danger of tuberculosis from milk had been vastly exaggerated. In the first place, tuberculosis was present to a considerable extent in the milch cows of all civilized countries, though the extent could not be stated by an average percentage because of the very great variations in different herds. In the next place, a tuberculous cow might produce milk impregnated with tubercle bacilli. Again, if the tuberculosis was located in the udder, the cow would produce milk that was impregnated with these bacilli. It was still uncertain whether a cow having tuberculosis anywhere else than in the milk glands could, under ordinary circumstances, produce milk with the tubercle bacillus therein. Of course he did not refer to a condition of general tuberculosis. Milk containing the tubercle bacillus might produce tuberculosis in a person using that milk. The foregoing statements he believed no one would question, and, this being allowed, the next question to consider was, How great was this danger of contracting tuberculosis from partaking of milk? It was probable that this danger was vastly less than had been supposed for a few years. The great seat for tuberculosis in mankind was the lungs, and the entrance of the disease into the lungs was, of course, by respiration, and not by swallowing. Again, if the bacteria in milk produced tuberculosis in man, they would more likely produce intestinal tuberculosis; yet intestinal tuberculosis was not so very common in mankind. Moreover, the bacteria in milk must run the gauntlet of the gastric juice and the hydrochloric acid contained in this juice, as well as the intestinal juices before they had any opportunity to enter the system and do any harm.

Probably Different Germs for Human and Bovine Tuberculosis.—It was also extremely probable that the variety of tubercle bacillus producing the disease in man was slightly different from the one producing the disease in the cow. They belonged to the same species, but, within a few months, very good evidence had been collected to the effect that the tubercle bacillus for the cow was not particularly pathogenic for the human being, and *vice versa*. It must also be remembered that tuberculosis in mankind was decreasing in all civilized communities, while tuberculosis in cattle was increasing very rapidly. This decrease of tuberculosis in mankind was equally great in the United States and in England, where milk was drunk raw, as it was in Germany and continental nations generally where the milk was customarily drunk in a practically sterile state. All these facts seemed to the speaker to indicate that the danger of tuberculosis from the milk had been grossly exaggerated. Undoubtedly there was a danger—to young children, perhaps, a considerable danger—but there was danger in going to the theatre, and he was inclined to think that the adult ran more risk from going to the theatre than from drinking ordinary raw milk.

Other Less Common Infections.—It was probable that the cow sometimes had scarlet fever and diphtheria, and, if this was the case, these bacilli might at times get into the milk, and distribute these diseases to children. While there was a probability, such infection was not very common. Another danger was acute enteritis produced by milk. However, of the first class of diseases—those coming from the cow—tuberculous infection was the only one of much importance.

Typhoid Infection.—Of the diseases coming to the human being by secondary contamination, typhoid fever stood out pre-eminently. It was well known that many epidemics of typhoid fever had been traced to the milk supply; within the last five years undoubtedly as many as fifty such epidemics had been traced to such a source. The reason for this was that the typhoid bacillus was capable of multiplying and growing in the milk, so that if only a few typhoid bacilli got into the milk, they would multiply rapidly. This was in sharp contrast with the behavior of the tubercle bacillus, which did not multiply and grow in milk. An occasional epidemic of scarlet fever or of diphtheria could be traced to secondary infection with the germs of these diseases, though no cases of this kind were on record in this country.

Diarrhœal Diseases.—A large proportion of the many intestinal troubles observed in hot weather could be traced to milk, but not to any particular bacillus or germ. They were the result of the abundant growth of many bacteria in the milk and the formation of certain toxins. Probably most cases of cholera infantum could be traced to milk in which there had been an undue multiplication of some of the common forms of bacteria not ordinarily looked upon as pathogenic.

Pasteurization.—It was impossible for milk dealers to insure the cleanliness of their milk in the present state of civilization in this country. Physicians and scientists might demand it; they might hold it up as an ideal, but we should not forget that "it was a condition and not a theory that confronted us." The speaker said that he heartily agreed with the preceding speaker regarding the undesirability of sterilization and pasteurization; nevertheless, with the present state of our milk supply we could not reject sterilization and pasteurization on the theory that they would encourage uncleanliness in the dairy. The significant fact was recalled that pasteurized milk was sold on a large scale in the city of Copenhagen at the same price as other milk, and the reason given for this was that less care was required in the cooling and handling of milk intended to be preserved in this way before being put on the market.

Good Milk Demands a Good Price.—He would reserve pasteurization for special instances. In conclusion, he would say regarding the quality of milk that everything which tended to cheapen milk did more to lower the standard of quality than almost anything else that could be done. If good milk was wanted, a good price should be paid for it.

The Work of the New York Board of Health.—Dr. Herman Betz, chief inspector of the milk in the health department, discussed the work of the board in connection with the inspection of milk. He said that the borough of Manhattan was divided into nine milk inspection districts. There were ten milk inspectors, and each district comprised about six or seven hundred milk stores. In 1899 the inspectors had made 8,047 inspections, examined 48,832 specimens of milk, and caused 117 arrests. The fines collected had amounted to $3,705. It was worthy of note that only eighty-four quarts of milk had been destroyed in the year 1899, although a total of ten million pounds of foodstuffs had been condemned in that year by the health department. Dr. Betz described in detail the apparatus employed, and the method of conducting the inspection of the milk, and the collection of samples for analysis. To facilitate the work of the department in tracing any individual can of milk, the cover of each can was marked with the name of the dealer, the road bringing it into the market, and the number of the station whence it came. If the analysis of a suspected sample of milk showed that it was more than five per cent. low in solids or three per cent. low in butter fat, a warrant was issued for the arrest of the milk dealer, and prosecution was commenced. Since 1896 every milk dealer had been required to obtain a permit from the health department, which was issued only after satisfactory inspection of the place from which the milk was to be sold. This permit was revoked, and the dealer no longer allowed to continue in the business, after he had been arrested and convicted twice for selling milk below the required standard.

Condensed Milk from Skimmed Milk Not on Sale Here.—In reply to the criticism of Major Alvord, Dr. Betz said that no condensed milk made from skimmed milk was allowed to be sold in this city. Only that very day two warrants had been issued for the arrest of dealers selling such an article. The department had succeeded in absolutely driving out from the city milk containing chemical preservatives.

The Question from the Milk Dealers' Standpoint.—MR. A. CUDDEBACH took up the discussion from this point of view. He said that the milk sold now contained much more butter fat than formerly, and this, he believed, was largely attributable to the quite general adoption of bottled milk, and the education of the people to look at the depth of the layer of cream in the bottle. The general tendency to consolidation among the milk dealers could also be traced to the custom of bottling the milk, because small dealers could not afford to bear alone the expense of such business. This consolidation also permitted the use of ice-cars for transportation where it would otherwise be impossible. The milk within half an hour after being received was packed in ice, and remained so packed until sold to the consumer. He had found that the centrifuge removed all dirt visible to the unaided eye. When the centrifuge was used, even though no butter fat was removed, the cream did not rise so readily, and hence to the public the milk did not appear to be so rich as when it had not been subjected to this process. The great obstacle that the milk dealer had to surmount was the lack of appreciation on the part of the public of many of the efforts made to secure better milk; hence such efforts were not commercially successful.

Some Milk Dealers Possessed the Milk of Human Kindness.—MR. L. B. HALSEY spoke on the same topic. The occasion seemed to him unique, for, in a long experience in this city, it was the first time the milk dealers had been cordially invited to meet the medical profession in the discussion of this very important subject. The discussion had impressed him chiefly with the thought that the milk supply of New York City was not so bad after all, and, indeed, was better than when the discussion had been opened. It was a grievous wrong to suppose that there were not in this city some milk dealers who were desirous of improving the milk supply purely for the good of humanity, and entirely aside from selfish interest; nevertheless it was but just that the milk dealer should receive an adequate compensation for effecting an improvement in the milk supply.

Adequate Compensation Essential.—Such improvement presupposed that the dealer had required of the dairymen better care, better food, and better environment generally for the cows, and better handling of the milk. It meant that the milk must be aerated and promptly cooled and quickly delivered to the transportation company. All this certainly could not be accomplished without proper remuneration. He thought all milk dealers here would agree with him that it was impossible, under present conditions, to distribute milk in small quantities to families at less than eight cents per quart.

The Wealthy Citizen Blocks Progress.—The speaker called attention to the fact that the wealthy citizens of New York actually blocked progress toward getting an ideal milk supply, though perhaps unconsciously. These people give a stated sum to their chefs, and these high functionaries demand from ten to twenty per cent. commission, and if the milk dealer was sufficiently liberal in this respect almost any kind of milk would pass muster. The hands of the conscientious and progressive milk dealers in this city were upheld chiefly by the physicians and by those earnest and intelligent mothers who spared neither pains nor money to secure for their children the best and most wholesome food.

Our Health Board's Methods Antiquated.—DR. H. PIFFARD said that the chief trouble with the milk supply of this city had been the improper regulations of the milk traffic by the health board many years ago, and which had been allowed to remain. He had been informed that the improvement that had been made had resulted from the efforts of the commercial men, and not of the health board. The standard of three per cent. of butter fat was very low when compared with the general average for the cows in this country. Dr. Piffard expressed himself as in favor of having the standard of milk properly defined, and also allowing other and inferior milks to be sold at a lower price.

Double Standard Absurd.—The double standard of three per cent. butter fat and four per cent. total solids had been shown some time ago by Major Alvord to be injudicious. He had shown that the farmers would sophisticate the milk in order to bring it up to the required standard of total solids. It had been shown that the casein varied directly with the proportion of butter fat. With the minimum of butter fat and the maximum of casein one might feel pretty sure that the milk had been sophisticated. In certain counties, notably Cortland, this absurd double standard had demoralized the dairy interests. For example, many of the cows would furnish four per cent. milk, but as such milk would not bring one penny more in New York market, and cows yielding only three per cent. milk were cheaper, the dairymen had sold their better cows, and had bought in their place inferior ones. This was the way in which this double standard had demoralized the dairy industry. Dr. Piffard recommended that the milk for this city coming in cans should be taken only from an area included in an east-and-west line drawn through Albany, and a north-and-south line drawn through Binghamton.

Special Committee Appointed.—On motion of DR. WALTER LESTER CARR the president of the Medical Society of the County of New York was requested to appoint a special committee to consider the possibility of a commission to improve the milk supply of New York, the committee to report to the comitia minora the result of its deliberations.

Nocturnal Enuresis.—Mullein oil in five-drop doses on loaf sugar, on retiring.—ED. *Experience*, December, 1899.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Ninety-Fourth Annual Meeting, Held in the City Hall, Albany, January 30 and 31 and February 1, 1900.

WILLIS G. MACDONALD, M.D., OF ALBANY, PRESIDENT.

Third Day—Thursday, February 1st.

(Concluded from page 213.)

Report of Committee on Medical Expert Testimony.—DR. RANSOM, of Dannemora, presented this report. It stated that a bill had been introduced into the legislature providing for the registration, certification, and qualification of medical experts, and the passage of this measure had been urged by the committee, but to no avail, the bill failing to be reported out of the judiciary committee. This failure was due to a lack of proper support by the medical profession at large. After consultation the committee felt justified in stating that there was no prospect of obtaining any corrective legislation at this time in this direction, in view of constitutional restrictions and limitations, and more especially because of the attitude of the legal profession concerning any innovation in this direction. Indeed, it seemed to be the consensus of opinion that no such legislation could be applied even if enacted. The committee indorsed the suggestions made by the president of the society in his inaugural address before the present meeting, *i.e.*, an appropriation for a State cancer laboratory.

On motion of DR. CHAUNCEY P. BIGGS, the society expressed its formal approval of the work being done by Dr. Roswell Park and his associates at this laboratory in Buffalo, and requested that State aid be continued to this institution.

The Spleen: its Shape and Relation to the Chest Wall and Abdominal Viscera.—DR. LUZERNE COVELLE, of Ithaca, read a paper with this title. He stated that in four well-known text-books on anatomy, the descriptions of the size, location, and shape of the spleen varied considerably. His own observations showed that the spleen lay obliquely across the ribs, extending toward or to a line dropped vertically from the posterior border of the axilla to the eleventh rib. The angle of the ninth rib was approximately a rib-space below the inferior angle of the scapula. The posterior axillary line nearly touched the tip of the eleventh rib. The highest point of the spleen lay about one rib-space below the inferior angle of the scapula, when the arms were hanging naturally. The innermost part lay about double that distance from the spine. The outermost point about touched the posterior axillary line. The anterior and posterior borders lay under the cover of the ninth and tenth and eleventh ribs. The spleen was often very movable. The child's spleen was much larger in proportion and reached much higher and farther forward. The spleen of old age is the reverse of this.

Supra-Vaginal Hystero-Myomectomy.—DR. I. S. STONE, of Washington, D. C., reported in this paper twelve cases in which tumors of greater or less size had been removed from the uterus, and in all of which considerable traumatism had resulted. The object of the paper was to show that there was relatively a greater mortality from the operation of myomectomy than from ordinary hysterectomy.

Atresia of the Vagina.—DR. F. W. HIGGINS, of Cortland, read this paper. He stated that in all the varied etiology of atresia of the vagina, diphtheria may be considered as one of the rarer causes. He had recently operated successfully upon a typical case due to this cause. Twenty-four ounces of blood had been found in the dilated uterus and vagina. Attention was called to the importance of early operation before the Fallopian tubes were affected, and also to the necessity of strict asepsis. He recommended flushing the cavity with hot saline solution, wiping dry, and packing with iodoform gauze.

Spontaneous Discharge of Cerebro-Spinal Fluid from the Nose.—DR. W. FREUDENTHAL, of New York, reported a case of this kind, and stated that he knew of only one such case having been previously reported in this country. His patient used more than twenty handkerchiefs daily because of a constant dribbling of a watery fluid day and night. Before this flow had commenced there had been serious symptoms of brain pressure, and these symptoms had recurred once or twice, when, for some reason, the flow had been interrupted. The original cause was probably pressure produced by a tumor, and life had been prolonged by the formation of an opening and the discharge of sufficient cerebro-spinal fluid to prevent dangerous cerebral pressure. A chemical analysis of the fluid showed the presence of albumin and a substance which reduced glucose.

Inguinal Hernia: Comparative Results of Radical Treatment by Injection.—DR. THOMAS P. SCULLY, of Rome, in this paper spoke highly of the present results obtainable by the Bassini operation. But for the laboring classes, to which long confinement in bed was a serious matter, he recommended the Hecton injection method. These injections should be made under strict asepsis, being repeated once a week for about four weeks. An accurately fitting truss should be applied after the first injection, and should be worn at least two months, though it was preferable to use some form of light protection for six months longer. He had treated one hundred and forty-eight cases by this method. Of the one hundred and twenty single hernias, fifty-eight, or forty-eight per cent., had had no recurrence after one year, and of forty cases traced after two years twenty-six per cent. were not wearing a truss. All of the sixty-two cases not resulting in cure had been more or less benefited. The greatest success had been achieved in the recent hernias.

DR. A. M. PHELPS, of New York, deprecated this attempt to revive a method which had been proved by a Boston commission to yield ninety-five per cent. of relapses. Dr. Phelps then described his operation, and the use of the network of fine silver wire to assist in closing the canal.

Officers Elected.—Officers were elected as follows: *President*, Dr. A. M. Phelps, of New York; *Vice-President*, Dr. George Seymour, of Utica; *Secretary*, Dr. F. C. Curtis, of Albany; *Treasurer*, Dr. O. D. Ball, of Albany.

THE NEW YORK MEDICAL UNION.

Meeting of December 26, 1899.

DR. LE ROY W. HUBBARD, PRESIDENT, IN THE CHAIR.

The Results of the So-Called Conservative Treatment of Appendicitis.—DR. SAMUEL LLOYD read a paper with this title (see page 226).

Discussion.—DR. ROBERT T. MORRIS: We all know what the real conservative treatment is to-day; it is not a matter for discussion. It seems to me, at the present time, we are to be guided by a knowledge of the pathology of the disease, rather than by any personal experience. The time for that is past. There are now few subjects better understood than appendicitis. We know the causation thoroughly, the pathological changes thoroughly, the symptomatology thoroughly, and there is hardly any part of the entire subject not within our knowledge. Therefore to-night

I shall confine my remarks to a few of the points brought out in the paper.

In the first place, I am glad Dr. Lloyd is one of the men who keep records of the cases not operated upon. Few physicians keep good records, and they speak from a standpoint of memory and of incomplete observation. It is a difficult matter to get a good collection of statistics such as Dr. Lloyd has. I have operated upon many patients who are still reported as cured by medical treatment. We know to-day that more than ten per cent. of all appendicitis patients have hard concretions in the appendix; we know to-day that more than eighty per cent. of the patients who have had one attack have mucous inclusions, more or less complete. This percentage does not include soft fecal masses which predispose to appendicitis. Nature makes efforts to throw off this fecal matter, and I am sure that a good many cases are caused by soft fecal masses in the appendix. There follows a spasm of the muscularis of the bowel which gives rise to a catarrhal inflammation with consecutive infection of the appendix. When the guarding epithelium of the mucosa is damaged infection follows. In the report of the cases treated without operation we note two points not usually brought out by writers. Almost all of the patients who come to me after having had one, two, or three attacks give a history of ill health dating from the time of their first attack; and yet they kept about their work, appeared to be quite well, were congratulated upon escaping operation, etc. Experience goes to show that many persons who report themselves in good health have had constipation, or gas formation, and do not feel vigorous or ambitious. They do not enjoy the enterprise they formerly did, and yet they say that they are pretty well. This condition of inferior health is due to several causes: First, it is often due to infection from a mucous inclusion; secondly, it is often due to adhesions of the bowel inhibiting peristalsis; thirdly, it is sometimes due to reflex disturbance of Auerbach's plexus and Meissner's plexus, fermentation taking the place of digestion.

There is not much difficulty in palpating the appendix; if one will give attention to it he will become expert. I have no doubt that most of the members present have no difficulty in palpating the ovaries and tubes; any man who can palpate the oviducts can palpate the appendix as well. I have frequently done it before the class. To do it one must train his finger ends. This matter of palpating the appendix should be acquired by any one who intends to express an opinion on the subject of appendicitis.

Patients refusing to have an operation performed is an experience I do not have, so I do not know how to discuss that point. It seems to me that patients are always ready for an appendix operation. I count upon that fact in consultations. Usually it is the cook, or the mother-in-law, who is opposed to the operation, not the patient. I have been called in to unravel this knot many times, and, instead of arguing for several hours at ten dollars per hour, I say, "Let us leave it to the patient." Patients say, "Operate." Of course I am referring only to acute cases, cases in which there is an acute progressive inflammation. In the interval cases I have frequently had occasion to ask for delay, in those cases in which the patients have had the management of large business affairs, and in which they ask for a delay of one, two, or three months; in these cases I often say: "Wait; we are ready to operate; but let me know at once when symptoms of acute recurrence make themselves known." But I cannot now recall a case in which there was acute suffering and the patient did not say, "Operate." It is a common thing for patients to postpone operation because of the idea that they might save time by it. One of my patients, who has been but nine days in bed since operation and goes home to-day, had previously been eight weeks in bed trying to save time. An idea that many patients have is that they lose time if operated upon. If operated upon, they usually spend but nine or ten days in bed, unless there is abscess complication at the time of operation.

Dr. Lloyd's point about recurrence after abscess had emptied into the bowel is a common experience. No one knows where the abscess is going to empty, whether into the bladder, or into the iliac vein, or elsewhere, and yet the patients may have recurrence of the attack. This we know from the pathology of the disease. I had one case in the sister of a physician who evacuated pus from the mouth after perforation of the lung, and from the vagina at the same time; nearly one gallon of pus was thus evacuated. She recovered and was congratulated perhaps upon escaping operation; yet she had a subsequent attack, was operated upon, and the appendix was removed, and it was a pretty good appendix. A mucous inclusion was present.

Patients suffer less under proper surgical treatment than under medical treatment. The replies of patients, ten in number, who had been operated upon, were published in the third edition of my book; they all made the statement that they suffered less under the surgical treatment. Several of these ten were abscess cases; several of them had had many attacks and had been subjected to different kinds of treatment, and all give testimony which I published.

After all, it seems to me that we are to be guided by our knowledge of the pathology of the disease rather than by personal observation.

Dr. Foot: I was called by a young surgeon of this city about one year ago to see an unusual case of appendicitis. A young lady, in pretty good health and well educated, asserted that she had passed hairs from the rectum, and the doctor had been shown some of the hairs, which were partly extruding. She was very indignant at the suggestion that she had introduced the hairs herself. The question of dermoid cyst was gone over, and a history of chronic appendicitis was elicited. We operated upon her and removed the appendix. She made an excellent recovery. A few days ago I met her and I inquired about the hairs. She told me she had passed hairs, had been operated upon, and had been cured of all symptoms, no more hairs appearing.

Dr. A. F. Currier: I cannot help thinking, as Dr. Morris discussed this question, that while he always discusses this question with great amiability, the question of conservative treatment of appendicitis, yet it is a great deal like the old bull and the piece of cloth. I feel much gratified with the series of cases which we had read to us to-night, because the older in experience I become in the treatment of this disease the more convinced I become that these statements which have been made are facts. That is to say, if a person has an attack of appendicitis he may get well of it; we cannot say he will not. We never can say that a person will never have another attack. That is the argument that I always make to people now, at the time I first see them. Most of the cases that I now see are in the acute period, and my experience has been limited to that form of the disease. I can bear out from recent experiences the statements of Dr. Morris regarding the relief which cases obtain after surgical work is done. I remember an operation done a few weeks ago on a man weighing three hundred and sixty pounds; in this case I defy any man, including Dr. Morris, to palpate the appendix. He was a carpenter and suffered for days and weeks, going around with pain in his side. He suffered acutely. I operated, and after he came out of the ether I asked him about the pain, and he said it was all gone. He has not complained of pain since. I also remember the case of a boy, operated upon a few weeks ago, and he gave the same story regarding the pain. That is an important point. In the course of quite a considerable number of cases operated upon I could recall but two cases in which I could feel any regret at adopting the surgical procedures. There is another class of cases in which the patients feel that they are going to die, and they decline operation. One of these cases I remember had the diagnosis made of appendicitis, and the case seemed clear enough; there were pain in the right side, induration, and other symptoms of this trouble. I saw her one night. The next morning I again saw her, and she stated that the pain was all gone, and she declined to have the operation done. The doctor in attendance said I had come to operate, and so the operation must be done. I found the appendix not very large, but it was diseased. There was some peritonitis, but I also found an enormously hypertrophied liver. The husband threatened to sue me, but the woman has been perfectly well since, and now rides a bicycle. Another case was that of a woman who had been ailing for some time, and the diagnosis of appendicitis was made; the abdomen was opened, but there was not found much inflammation of the appendix itself. Now, what impressed itself upon me was the fact that all were cases of peritonitis, and when peritonitis existed we could not always tell whether we were dealing with an appendicitis or not. I have often asked why it was that peritonitis chooses this portion of the abdomen; is it because the appendix lies there, and is subject to changes? It is certainly a fact that in a great many cases I have seen, in which there is no abscess and the appendix was buried in adhesions, the circulation was interfered with and was a constant menace to life. The more experience I get the more satisfied I am that true conservatism means the relief of the offending organ.

Dr. P. J. Lynch: In olden times we generally found the cases associated with peritonitis. I have seen, what all gentlemen who have practised medicine have seen, several cases which were treated conservatively; a few of them got well after two or three relapses, and some are now well after a period of five or six years and have no constitutional disturbances whatever. From my own experience with these cases, and from the fact that the general consensus of opinion is in favor of operative interference, I now turn them over to the surgeon. There is only one thing I regard as the probable reason why all patients do not select the surgeon in the treatment of this disease; it is because a certain percentage, surgically treated, have died cured. That little fact impresses the uneducated, and they are disinclined to have operation performed. I myself am disposed to turn my cases over to the surgeon, even though I think that many will get well without interference.

Dr. F. Huber: A long period of freedom took place in appendicitis in my own case. Seven years ago I had typhoid fever. During convalescence I developed appendicitis, from which I recovered under the use of ice and small doses of opium and rectal enemata. Seven years later I awoke one morning and I knew then what I had. Thirty-six hours later I was placed on the table, my belly was opened, and was found to be filled with serum. My appendix was distended and a large concretion existed. In the interval between the first and second attack I was absolutely free from any manifestations at all.

Dr. A. Trautman: Of the last four cases I have had, three were not operated upon and got well, and one was operated upon and died the following day.

Dr. Ralph Waldo: I belong in the same class as Dr. Huber, for seven years ago I was operated on for appendicitis. There were two perforations, and it was necessary to pack the wound. The operation relieved the pain as well as many of the other disagreeable symptoms.

There are several things you should properly impress upon your patients. One is that the operation for appendicitis, properly performed, does not kill. If performed at an improper time it may not cure your patients. That is of vital importance to your patients. You can tell them that it is just as proper to consider that the glass of water that a patient took during his attack of pneumonia caused the death of the patient.

I am sorry that I must disagree with Dr. Morris regarding the etiology of appendicitis. I recognize the fact that in certain cases concretions and foreign substances have a good deal to do with the wounding of the epithelial surfaces which is followed by infection. The disease is an inflammatory one, and one or another variety of inflammation affects the appendix and neighboring structures in different degrees. There are many cases of appendicitis associated with intestinal indigestion, in which the latter is markedly improved, but not completely cured, after operation. I am thoroughly convinced that quite a large percentage of cases of appendicitis are simply an extension of an inflammatory disease from the colon into the appendix; the same as catarrh of the nose extends into the Eustachian tube, producing disease there and in the ear. In the same way an endometritis may extend and produce inflammation of the Fallopian tubes. I am thoroughly convinced that that is a prominent point in the pathology of this disease. It has been referred to. Concretions in the appendix, even hard ones or seeds, may not cause disturbance for a long period of time. In the same way one may have a hernia without any disturbances; as soon as it becomes strangulated we then have a local inflammation. The blood supply to the appendix is bad, and sudden attacks of gangrene may come on from conditions that in other portions of the intestinal tract would amount to. little. Appendicitis will not kill every patient if let alone. Any one will get the statements from his patients that Dr. Morris did in writing to the ten he operated upon. All of them will say that the operation afforded the greatest relief from their suffering, even in many cases in which the patients had marked sepsis before operation. If these patients are taken at the proper time, they will probably all be cured. This operation does not kill patients.

Dr. Hammond: It is hardly right for a neurologist to discuss this subject. I was very much interested and instructed by the paper. Of course, even though we are neurologists, we occasionally see cases of appendicitis; all practitioners do. It always seemed to me advisable in all of these cases to operate. When I say operate, I mean operate at the proper time.. We know that when a person has had one attack of appendicitis he will probably have another attack. In considering the question of operation, we should look into the present condition of the patient and consider the history of the case. It is our duty to urge operation when we know that it can be done so safely and without any danger at all, and that it will spare the individual the chances of a future attack of appendicitis and death. Therefore I recommend that these cases should be operated upon. If they have a mild attack, conservative treatment may carry them through it; but as soon as recovery takes place let them be operated upon, and so have no chances of future trouble.

Dr. Hubbard: Dr. Morris spoke of the ill health of the people after recovery—or so-called recovery—following the conservative treatment; I should like to ask the doctor to tell us what, in his experience, is the subsequent condition of the operative cases as to their general condition; also, whether the patients operated upon had subsequent attacks; that is, of course, whether they have had attacks presenting symptoms similar to appendicitis. I should also like to ask him if, from his experience, he would favor operating after the first attack. I speak of this because, at a discussion of a medical society recently, a man reported some cases and made the statement in regard to the cases operated upon, that he would not advise operation after an apparently perfect recovery from a first attack.

Dr. Lloyd closed: In the title of my paper I used the words "conservative treatment" because that is the usual way of referring to the temporizing methods in vogue; I do not believe in it. A few years ago it was more difficult to obtain the patient's consent than it is to-day; I have no difficulty in persuading patients nowadays to be operated upon. A few years ago the mortality was greater, because the operation was undertaken at a less favorable time. There is a set of patients who wait nowadays; that is, they decline operation after we have tried to get them into the interval. They put off the operation on account of social or business engagements; they enjoy apparently good health, and they think they will select a more convenient time for operation. The cases I tried to get together in this paper are those that were treated medicinally and were then carefully followed up from the first attack to the final result. We find cases constantly reported as cured after medical treatment when we know they have had recurrences. Many of these cases have passed through many hands before they get to the operator. The idea I had in mind was to get the actual results or the present conditions.

Regarding the question of continued ill health, there is a good deal in that; many do not have ill health, but many do have it. They often complain of a colicky, flatulent condition in the abdomen. There is more or less colic, and constant distress from intestinal indigestion. These patients sometimes have diarrhœa, and sometimes constipation. Every once in a while they will tell you that they have pain upon pressure in the right iliac region. Those cases that continue to have more or less discomfort must be operated upon. Regarding one of the fatal cases in the series reported, the patient was treated in the country, in a town where they did not know appendicitis; they never had made the diagnosis of a case; he could not have been operated upon. Later, while in Montreal, he had another attack, and the third attack came on while he was at business one morning; they sent for me and I called an immediate consultation. Waiting was advised, to see if the case was one of appendicitis or rupture of adhesions following some severe exercise. That night the appendix perforated. At the operation a gangrenous condition of the bowel was found, including the appendix and even extending to the aponeurosis of the external oblique. He was acutely septic. These are the cases that operation will not save unless they are operated upon early.

Dr. Hubbard asked regarding the question of operating in the first attacks. I stated that I believed that a single attack of appendicitis inclined the patient to recurrent attacks, and to recurrences that were progressively more severe; that is shown by the histories of the cases. I cannot recall ever operating in a case the second time, because I began, early in my experience, to search for and remove the offending organ and not to be satisfied with simple incision and drainage. I cannot now recall a single patient who has had a second attack.

Regarding the question of how long to wait, I believe that the interval operation is the best. But the question really is, how to decide whether the patient will reach the interval or not. I believe that every case, when the symptoms are progressive after twenty-four hours, should be operated upon. If the symptoms are not progressive, if no signs of an acute infection are present in twelve hours, if the temperature goes down and the tenderness is not increased, and the pulse remains of good calibre, it is well to wait for the interval; even then you should be ready to operate the instant there are any indications of an increase in the inflammatory symptoms.

Medical Items.

The Recognition of Renal Typhoid. — According to Amat the renal form of typhoid fever manifests itself in a subsidence, sometimes an absence, of intestinal symptoms, supplanted by signs of an acute hemorrhagic nephritis. The temperature from the outset is hyperpyretic; the prognosis is very unfavorable, the prostration great, and delirium frequent. Dr. Rostoski (*Münchener med. Wochenschrift*, No. 7, 1899) during the past summer observed two cases of typhus renalis in Leube's clinic, which differed from the general description of these cases. In the first instance the acute hemorrhagic nephritis was plainly an exacerbation of an existing chronic nephritis. It lasted fifteen days, and was present before the roseola, enlarged spleen, Widal-Gruber diazo reaction, or the typhoid stool. The fever was not hyperpyretic, and the course of the typhoid was relatively mild. In the second case the symptoms were ushered in by a moderate rise of temperature without the characteristic curve, and presented the picture of a hemorrhagic diathesis with muscle pains and normal hemorrhages. Casts were as yet absent from the urine. They first appeared six days later, were abundant, and were preceded by a chill and a rise of temperature to 40.2° C. Other signs of nephritis were absent throughout the entire course of the disease. Two days later enlargement of the spleen was noticeable. A positive Widal-Gruber reaction was obtained a few days after this, and on the following day large numbers of typhoid bacilli were found in the urine. Notwithstanding this, the roseola was slight and evanescent, the fever was markedly intermittent in character, and the nephritic symptom persisted, although the quantity of blood in the urine gradually diminished. The kidney symptoms were aggravated by a complicating peritonitis, and it was twelve weeks before the urine was free from albumin. This case differs from Amat's type in that the general condition of the patient remained good, and there were no delirium, no hyperpyrexia, and no severe headaches.

Lord Curzon and the Plague.—The new viceroy of India is adding to the harvest of golden opinions he has already reaped by his courageous and energetic behavior in the presence of the plague. Just as soon as the dark and disquieting rumors of a steady smouldering of pestilence in Bombay and Poona were confirmed by a sudden increase in the number of cases, threatening another epidemic, he promptly left the cool security of Simla for a thorough inspection in person of the sanitary arrangements of the infected districts. Before leaving he took the wise precaution of having himself and his entire party inoculated with prophylactic serum, and is in consequence able to urge its use with telling effect. As he shrewdly puts it, "A measure which changes a death rate of from seventy to eighty per cent. into one of from fifteen to twenty, even in those who are attacked after submitting to it, to say nothing of the large proportion who are completely protected by it, is one which no sensible man can afford to neglect." Is it any wonder that his speeches are said to be making a deep impression upon the native population, and that inoculation is becoming positively popular? As a means of cure after the disease has actually made its appearance serum inoculations have not proved very successful, but while still on trial their preventive effects have been most encouraging, although the protection conferred does not last a very long period, so that frequent re-inoculations are advisable.—*English Outlook.*

The Effect of Colored Light on the Nervous System.—It has long been claimed that colored light has a special effect on men and the lower animals. It has been asserted by some that the lower animals grow more rapidly in violet than in white light. On the other hand, Flammarion has found that silkworms grow least rapidly in the violet rays. Experiments on the nervous system are in better accord. They show, according to Henri de Parville, writing in *La Nature*, Paris, that the red end of the spectrum is exciting to the nerves, while violet, blue, and green are calming. It is well known that turkeys and bulls are excited by red; on the other hand blue glasses are often used to quiet horses. In the photographic establishment of the Messrs. Lumiere, in Lyons, France, sensitive plates are prepared in a large room by green light. Formerly when red light was used the workmen always sang or gesticulated at their work. Now they are calm, never speak, and assert that they are much less tired in the evening than they were previously. Every sufferer from nerves knows that a gloomy day affects him unfavorably, while the first ray of sunshine makes him gay again. It has been suggested that the green of vegetation, the blue of the sky, and the blue-green of the ocean may thus have a powerful influence in calming the spirits. Parville, however, cautions his readers against too sweeping conclusions. All that we can say is that colors certainly appear to affect the organism, and that the subject will bear further investigation.— *Public Opinion.*

Do Animals Feel Pain Less than Men?—What we call an "ear for music" is almost an added sense in some people as compared with others. Even in animals of relatively high intelligence, such as dogs and monkeys, there seems to be reason to think that their perception of pain is much less acute than in humans. After serious operations under chloroform they are often frisking about a few minutes after recovering consciousness, and even jumping from the floor on to the operating-table in a way that forbids the notion that they are in suffering. In all animals the skin is possibly less sensitive than the human skin. It is covered with insensitive hair, and, though no doubt more sensitive than any other part of the body, it is presumably on quite a different plane of sensitiveness from the human skin. In human beings the sensitiveness of the internal organs is very small compared to that of the skin. Examples of this are familiar to every one. While in health no one knows anything of his "inside"; he has no sensations from it. Even disease of a very serious kind can and often does go on for years in the internal organs without causing any sensation. The nerves of the internal organs are much more concerned with regulating functions and controlling the size of the blood-vessels than with the conveyance of sensory impressions to the brain. Life would, in fact, be unbearable if the functions of animal life in a normal state caused sensation; and they would cause it if the organs were richly supplied with sensory nerves. Every surgeon knows, for example, that the human intestine is, when its muscular coat is at rest, almost as insensitive as the hair or nails. In the operation of opening the intestine often required in the presence of malignant disease, the cut in the skin and the business of fixing the gut to the skin would be very painful, and deep anæsthesia is required. Two days later, when the gut in its new position has to be opened, the patient is told to shut his eyes and he feels nothing; he does not even wince while a wound nearly two inches long is made in the intestinal wall with either knife or hot iron. This has been proved by hundreds of cases, and certainly it is not to be explained as due to stoicism on the part of the patient. Other important operations have been done without anæsthesia, except for the skin cut, and without giving rise to suffering at all of a severe kind. It is most improbable that even the highest of the lower animals would feel pain where man feels none. On the contrary, from their smaller brain development they probably are less sensitive than man.—*Edinburgh Review.*

Sir William MacCormac.—English *Tit-Bits* of November 25th has the following sketch of this distinguished surgeon: "It is safe to say that the public do not know nearly as much of Sir William MacCormac as they ought to do, for Sir William is in the front rank of the world's surgeons, has had some stirring experiences, and has obtained a unique reputation. This is as a surgeon of wars, a battlefield doctor, and one of the best men in the world to take charge of Tommy Atkins when a bullet has unhappily made him unfit to fight for queen and country. Yet when two or three weeks ago Sir William patriotically offered his services to the government for the war against the Boers, and now when he has at last reached that vast operating-theatre in South Africa, many people have little idea of what Sir William MacCormac has really done. Many reasons account for this state of things. For one thing, the man of science, be he ever so distinguished, unless his science is of that popular enticing sort, like Edison's and Marconi's, does not get talked about in every home. Then the wars in which Sir William has served happened long ago, and they were not wars in which the soldiers of Great Britain were engaged. Lastly, Sir William is a modest man, and less has been said and written of him than almost any other celebrity of the day. Sir William is proud of the land of his birth. He is an Irishman and comes of a good Irish stock, which has had not a little to do with medicine. As a matter of fact, his father, Dr. Henry MacCormac, of Belfast, was about the first well-known advocate of the open-air treatment of consumption. His mother also was a Belfast lady, in which city Sir William was born in 1836. He received his education at the Royal Institution and Queen's College, taking his degree in 1856. He also studied in Paris. At twenty-five years of age he married Miss Katherine Chartres, of Belfast, and three years afterward he was admitted to the fellowship of the Royal College of Surgeons of Ireland. He became F.R.C.S. England in 1871, and in that year removed from Belfast to London, having secured the appointment of senior assistant surgeon and lecturer on practical surgery at St. Thomas' Hospital. When Mr. Le Gros Clark retired in 1873 he became full surgeon and retained that office for twenty years, when he was appointed consulting surgeon and emeritus lecturer on clinical surgery. When the International Congress foregathered in London in 1881, he was elected to the responsible office of senior honorary secretary. The duties were exacting, and to a large extent the success of the congress depended upon the way in which they were carried out. MacCormac performed them admirably—so admirably, indeed, that he was made a knight in consequence. He was then elected to the council of the Royal College in 1883, and has served as examiner since 1887. In 1887 he rose to the vice-presidency, again in 1893, and now, as most people know, he has the honor of filling the presidential chair for the fourth time. In 1897 a baronetcy was substituted for his knighthood, and last year he was further honored by admission to the knight companionship of the Victoria Order. He has a remarkable record of field service. When the Franco-Prussian war broke out in 1870 he realized that in it there might be an opportunity of discovering what military surgery was like, a discovery which he was very anxious to make. So he hastily packed up his traps and was in Paris almost as soon as the declaration of war had been made. To a certain extent he was drawing a bow at a venture; for, to tell the truth, he hardly knew what he might be able to do or even whether the Frenchmen would let him do anything at all. As soon as he reached the French capital he went to the Palais de l'Industrie, where the French National Society for aid to the wounded had established itself. In reply to his questions and his offer he was told that no foreign surgeons would be permitted to serve; but a few days later the Emperor gave his special sanction and welcome to any English or American surgeons who might offer their help. There was a little more delay, and then MacCormac was given instructions to proceed to Metz and report himself to the surgeon in chief there. . . . The young Irish surgeon was anxious to get to work as soon as there was anything to do, and the surgeon in chief assured him of the welcome his assistance would receive. But the French in Metz suddenly conceived a most inordinate dread of spies. It so happened that Prussian spies had just scored heavily, and the word went round for the keenest watch to be kept in the future. Several arrests were made of palpably innocent persons, the proprietor of the hotel in which MacCormac was staying being among the number. One evening, seated at the dinner table, MacCormack happened to speak a casual word to an American who sat next to him. As it turned out afterward, suspicions were held about the American, and the immediate result of the trifling incident was that MacCormac himself was suspected. Next morning he received a summons to attend the office of the prevôt-maréchal. The surgeon's papers, assisted by the evidence of a Metz surgeon, completely cleared him, but the latter advised him to leave Metz without any delay. Various French officers supplemented the advice in such a way as to make it almost a command, numerous threats being held out against him. Consequently, sadly disappointed and very naturally indignant at the treatment, MacCormac journeyed back to Paris. Still he was destined to get the experience he desired, and in this campaign too. At the beginning of the war the Americans in Paris appointed a committee to organize an ambulance. Owing to a dispute between this committee and its surgeons the latter separated, and in company with a few English friends formed an Anglo-American ambulance. There were eight English and eight American surgeons, MacCormac being in command of the English section and ultimately of the whole ambulance. Their services were promptly accepted, enthusiastically so, for the French straightway gave them 15,000 francs, horses, wagons, tents, and everything else they asked for, and promised all the money and stores they might need for the future. The ambulance was despatched immediately to Sedan, and it arrived there on August 30th, taking possession the next day of the Caserne d'Asfeld, which had been converted into a hospital for its use. Almost immediately the cannon commenced to roar, and the great battle of Sedan began. At night the ambulance went over the battlefield and had many of the wounded transported to their hospital. MacCormac was performing operations one after the other as fast as he could, and the same the next day, when the wounded were being brought along in a continuous stream. The night was far spent before he was able to leave the operating-table and seek a little rest. All through the war the work of the Anglo-American ambulances was a brilliant success. At Asfeld during that bloody September and October of 1870, six hundred and ten cases of injuries were treated, of which the comparatively small proportion of one hundred and thirty-seven resulted in death, and one hundred and thirty-eight operations were performed, sixty-one of which had a fatal termination. The experience Sir William MacCormac gained in the Franco-Prussian war he backed up afterward by further aid to the wounded in the Turco-Servian war."

Prognosis of Tetanus.—Although the prospects of recovery are poor in acute cases, the epigrammatic French saying, "Tant de cas tant des morts," is not justified. The prospects are better in the subacute form and in cases of chronic and head tetanus. Any patient who lives over six days has a fair chance of recovery. Lambert claims that even with the older methods of treatment the mortality is for acute cases only eighty per cent., being an average mortality of sixty per cent. for all forms. While the antitoxin treatment has effected a reduction of only five per cent. in the mortality of acute tetanus, it has reduced that of the chronic variety to sixteen per cent., a very material improvement. This increase in the chances of recovery is unfortunately limited to cases in which the incubation period is seven days or over.—*Nancrede's Principles of Surgery.*

The Operative Treatment of Uterine Fibroids.—Lockhart (*American Gynæcological and Obstetrical Journal*, December 18, 1899, p. 526) expresses the opinion that a uterine fibroid should not be interfered with unless it gives rise to serious symptoms, mental or physical. Curetting is merely a palliative measure, as is also in many cases ligation of the uterine arteries. Removal of the appendages should be merely a *dernier ressort*, as it practically never cures, and does not always even relieve. The operation of election should be either total hysterectomy or myomectomy. The latter is to be chosen when the tumor is submucous and pedunculated, when it is subserous and has either a pedicle or a well-defined border, or when several small nodules lie immediately beneath the peritoneum. Total hysterectomy is indicated when the tumor is submucous and non-pedunculated and the cervix cannot be dilated sufficiently to allow of morcellement, or when the tumor is interstitial, large, and subserous, without a pedicle, soft, fibrocystic, or undergoing degeneration, or when the presence of the tumor is complicated by disease of the appendages.

Leprosy Cases in England.—The members of the London Medical College and Polyclinic have been fortunate in the matter of leprosy demonstrations. We are informed that during the past six months no fewer than seven opportunities have been afforded for the inspection of cases of this malady, which in England is very rare. One of these patients, an excellent example of the macular form with tendency to tubercular developments, is expected to attend again. All the cases have been in Europeans who have lived in leprosy districts, and in only one was the patient of mixed blood. One patient had lived in India in the army, another in Australia, a third in British Guiana, and a fourth in the West Indies. In no single case were there any facts suggestive of direct contagion from any known source. All the patients were still living with their relatives without precautions, and Mr. Hutchinson pointed out that no suspicion of contagion had occurred. In one the disease had been for some years completely arrested, while all the others showed the macular type.—*British Medical Journal.*

THE INOCULATION OF MALARIA BY THE MOSQUITO: A REVIEW OF THE LITERATURE.*

BY IRVING PHILLIPS LYON, M.D.,

BUFFALO, N. Y.,

CLINICAL PATHOLOGIST TO THE NEW YORK STATE PATHOLOGICAL LABORATORY, UNIVERSITY OF BUFFALO; INSTRUCTOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF BUFFALO.

THE idea that mosquitoes or other insects bear a causal relation to the spread of malaria appears to have been suggested in very early times, and has been expressed during the present century by various writers. In an excellent review of this theory, Nuttall [30, 35] narrates that it was mentioned nearly two thousand years ago by the Roman writers Varro, Vitruvius, and Columella, was referred to in 1848 by Nott, of New Orleans, as a fact already known, and was advocated in an elaborate article by King, of Washington, in 1883. Among more recent writers, the theory was suggested by Laveran in 1884 and 1891, by Flügge in 1891, Pfeiffer in 1892, and Manson in 1894. The belief that mosquitoes cause malaria is also found among the inhabitants of certain malarious regions in widely separated parts of the world.

The first experiments undertaken to test this theory appear to have been made by Bignami and Dionisi [3, 4] in Rome, in 1894, and resulted negatively.

The present scientific interest in the theory dates from Manson's[5, 7] famous support of it in 1894, and subsequently in his Goulstonian lectures, in 1896. Manson, noting the fact that flagellated forms of the malarial parasite were not observed in fresh blood, but appeared only after an interval of twenty minutes or more after withdrawal, concluded that the flagellated forms probably represented the first stage of an extra-corporeal † development of the malarial organism destined to preserve and continue its life cycle outside its human host. He believed that "the crescent body and the tertian and quartan spherical bodies which proceed to flagellation are the extra-corporeal sporulating homologues of the intra-corporeal sporulating bodies; that the flagellum is the extra-corporeal homologue of the intra-corporeal spore. Both types of sporulating plasmodium have corresponding functions, both arise from the same source; one is the germ of the plasmodium inside the human body, the other is the germ of the plasmodium outside the human body; both function in the propagation of the parasite." [7] He also pointed out certain resemblances between malaria and filariasis, and completed the analogy by advancing the theory that, as mosquitoes remove from the human body filaria nocturna and in turn act as host to this parasite, so also may mosquitoes remove and serve the purpose of host to the malarial parasite.‡ It is to be noted that Manson[5, 7, 10] did not think of the mosquito as an agent for inoculating malaria in man by its stick, but rather for removing the parasites from man, harboring them in its body during their development and reproduction, and then spreading them abroad in water and dust to reinfect man, and thus complete their double cycle of existence, just as in the case of filaria. He thought that, after the mosquito had fed on malarial blood, flagellated forms of the parasite developed in the mosquito's stomach; the flagella broke loose, penetrated the tissues of the mosquito, and there continued their extra-corporeal development and reproduction.

In 1895, Surgeon-Major Ross,[6, 7, 6] of the Indian medical service, became interested in Manson's theory, and, guided by personal directions given by Manson, began in India his epoch-making experiments with mosquitoes, which resulted in the first experimental evidence in support of the theory. At this time Ross allowed mosquitoes to feed on the blood of a patient containing the crescent form of the æstivo-autumnal malarial parasite. These mosquitoes were forthwith examined, and in their stomachs the parasites were found to have proceeded to develop into "spheres" and later flagellated forms. No less than forty or fifty per cent. of all the crescents developed into flagellates. Ross' investigations were then interrupted, and no further progress was made in the study at this time.

Manson[7] interpreted Ross' discovery in the following words: "We may conclude with confidence that Ross has thoroughly proved by direct observation my hypothetical conjecture that the stomach of the mosquito is a suitable medium for the flagellated phase of the plasmodium malariæ to develop in; and it seems to me that it is only a question of patience and technique to work out the remainder of the life-history of the parasite in this insect."

In 1896, Bignami[9] advanced the theory of the *direct inoculation of malaria in man by the stick of the mosquito*, comparing the process of infection to the one already known for the production of Texas-cattle fever by the "bite" of the tick, Pyrosoma bigeminum, and after a critical analysis and rejection of the claims of the air and water theories of malarial transmission, he reached the conclusion that, considering all known facts, "malaria behaves itself with regard to man as if the malarial germs were inoculated by mosquitoes."

In 1897, Ross[13] was given an opportunity to continue in India his investigations, and in August of that year succeeded in making a second and most important step toward the experimental demonstration of the mosquito-malaria theory.

Obtaining specimens of a species of mosquito that he had not previously observed, and which he described as a "brown species" and later as "dapple-winged" mosquitoes, he allowed them to feed on a patient whose blood contained crescents, and later in two of these mosquitoes he found peculiar large, round or oval pigmented cells, situated in the outer layer of the stomach-wall. The pigment granules resembled malarial pigment, and the pigmented bodies were found only in mosquitoes that had fed on malarial blood, and were not observed in hundreds of mosquitoes that had fed on healthy blood. Ross believed that he had at last discovered the malarial parasite in the tissues of the mosquito, a conclusion that has since, as we shall presently see, been amply demonstrated. In September, 1897, Ross[15] obtained a third case similar to the previous two, and also claimed to have found pigmented bodies in a "grey" mosquito that had fed on tertian blood, but he subsequently* decided that this case must be excluded, as due to a probable error.

---

* Read before the Buffalo Academy of Medicine, October 10, 1899.

† The words extra- and intra-corporeal are employed in this paper always in reference to the body of the warm-blooded vertebrate host, *i.e.*, man, birds, monkeys, bats, cattle, etc., and never to the body of the invertebrate host or insect.

‡ Laveran,[1] in 1884, first suggested the possibility that mosquitoes might "play a rôle in the pathogenesis of malaria similar to that in filariasis."

In the spring of 1898, Ross,[16] finding human malaria scarce, turned his attention to the investigation of the allied parasitic blood disease of birds, the so-called bird malaria, of which two forms existed, due respectively to proteosoma and halteridium. Working with birds infected with proteosoma, and feeding "grey" mosquitoes upon them, Ross subsequently found in the stomach-wall of these mosquitoes pigmented cells similar to those obtained previously by him in "dapple-winged" mosquitoes fed on human malarial blood. These pigmented bodies, which he called coccidia,† were first observed in mosquitoes on the second day after infection (feeding), and at this time were oval bodies, 6 to 7 or 8 μ in their long diameter, containing fine pigment granules exactly resembling those of proteosoma. In mosquitoes kept alive for three or four days after infection, the coccidia were found to have increased considerably in size and become spherical; their protoplasm showed granules, vacuoles, and irregularities, and the wall had become dense and showed a capsular appearance. They increased in size until they reached a diameter of 60 or 70 μ at the end of a week, and were then seen as wart-like excrescences protruding from the outer stomach-wall into the general body cavity. In some of these full-grown coccidia peculiar striated appearances were seen, and others contained several large sausage-like bodies. In a letter to Manson,[18] Ross summarized his conclusions as follows: "(1) Pigmented cells are found in the stomach wall of grey mosquitoes fed on crows, larks, and sparrows with proteosoma. (2) Pigmented cells are not found in control grey mosquitoes fed on healthy men, or men with crescent plasmodia, on healthy sparrows, on crows and larks or on crows and pigeons with halteridium. (3) These pigmented cells are found in the external coat of the stomach, and grow from a size of 6 μ in thirty hours to 60 μ at six days, and are probably coccidia. (4) Successive feeds by the same mosquito on the same bird are followed by fresh crops of young coccidia. (5) Similar pigmented cells have been found in mosquitoes fed on human gymnosporidia (Labbe)."

Continuing his investigations during the spring and summer of 1898, Ross[21, 31] found that the mature coccidia of proteosoma were of two kinds, one containing closely packed within its capsule a large number of delicate, thread-like bodies, often arranged radially about central points, and the other containing several large black spores. The mature coccidia on the eighth or ninth day ruptured and discharged their contents into the general body-cavity or cœlom, which contains the so-called blood or circulating juices, by which the thread-like bodies or "germinal spores" and the large black spores were distributed through the tissues of the body of the mosquito. The empty capsules of the coccidia remained *in situ* in the stomach wall. The thread-like bodies, when free, were found to measure from 12 to 16 μ in length, 1 μ in breadth, and were flattened in the third dimension. They contained chromatin granules, tapered at the extremities, and did not appear to possess independent movement: The black spores were 16 to 20 μ in length and 2 or 3 μ in thickness, were straight, curved, or twisted, with blunt ends, and were of dark brown or black color, with a sharp contour. The ultimate destiny of these black spores Ross did not succeed in determining. Pursuing the thread-like bodies through the tissues he found them collected in large numbers in the cells and ducts of a gland located in the anterior part of the thorax, whose main efferent duct passes forward and emerges at the tip of the proboscis. Ross, unaware of the previous description of this gland, which, in fact, had been fully described in 1888 by Professor Macloskie[2] of Princeton, supposed that he had discovered a new organ, and correctly interpreted it as a venemo-salivary gland, whose secretion was purposed to be injected into the wound made by the prick of the mosquito's proboscis in the flesh of its victim, and thereby occurred, he conjectured, the discharge into the circulation of birds of the numerous thread-like bodies or "germinal spores" found in the secretion of this gland, and doubtless destined to begin anew in birds the intra-corporeal life cycle of the proteosoma!

This assumption he proceeded to test, by allowing infected mosquitoes, after the time at which he had learned to expect the presence of the thread-like bodies in their venemo-salivary secretion, to feed on healthy birds, whose blood he had by repeated examinations assured himself was free from proteosoma. The result was as follows: "(1) Out of twenty-eight originally healthy sparrows subjected to the bites of grey mosquitoes previously fed on diseased sparrows, twenty-two, or seventy-nine per cent., became infected, all with a very large number of parasites, in from five to eight days. . . . (2) Out of two crows and four weaver birds, one of the crows and all the weaver birds showed a copious proteosoma infection within nine or ten days of being bitten by gray mosquitoes fed previously on sparrows with" . . . proteosoma. Control experiments with healthy mosquitoes and healthy birds resulted negatively, with one doubtful exception.

Ross had succeeded in these experiments in carrying proteosoma from birds to mosquitoes and from mosquitoes back again to birds. He had produced experimentally the complete demonstration of the truth of the mosquito-malaria theory as applied to proteosoma-malaria of birds, and he expressed his belief that what he had found true of proteosoma in birds would be found true of human malaria.

During the following winter (1898–99), Daniels,[33] working in Calcutta under Ross' guidance, confirmed in detail Ross' work on proteosoma, and expressed some interesting speculations concerning the destiny of the black spores.

In the mean time, also, Dionisi,[17]* of Rome, had been working on birds, and though he failed to infect them by mosquitoes, he nevertheless made the suggestive observation that in pigeons parasitic blood infections occur most frequently at the time of moulting, when, of course, mosquitoes have the best opportunity of attack.

In a paper presented to the British Medical Association, in July, 1898, Manson,[19] reviewing the mosquito-malaria theory in the light of the facts discovered up to that date, pointed out that his theory had assumed that the flagellum, developing in the mosquito's stomach after the mosquito had fed on infected blood, was the agent that penetrated the tissues of the mosquito to start the extra-corporeal cycle of the organism. This view was incompatible with the fact discovered by Ross that the coccidia found in the mosquito's stomach wall contained pigment granules, *because the flagellum was without such pigment.* This hitch in his theory might be overcome, he thought, by modifying the theory in accordance with certain observations which MacCallum, of Baltimore, had made in studying halteridium, a blood parasite of birds, closely related to the parasite of malaria and to proteosoma.

---

* See British Medical Journal, July 1, 1899, p. 4, footnote No. 11.

† Under date of December 31, 1898, Ross[31] wrote to the British Medical Journal that his opinion that these bodies were "coccidia" "is provisional. The true zoölogical significance of the mosquito stage of the parasites is a difficult subject, and will be discussed in the final report."

* Dionisi[22] also at this time discovered in the blood of bats parasites of two varieties, resembling morphologically the parasites respectively of quartan and æstivo-autumnal malaria. (I wish to express here my indebtedness to Dr. Francis E. Fronczak, of Buffalo, for his kind assistance rendered me in digesting the Italian literature.)

MacCallum,[12, 14] in the summer of 1897, had observed the following facts: The full-grown extra-corpuscular parasite of halteridium consisted of two forms, one flagellated, the other non-flagellated. The flagella, breaking loose from the flagellated form, approached the non-flagellated form and one of them penetrated its substance and entered it, resulting in a subsequent commotion of its pigment granules and a gradual change of its shape into an elongated, motile, pigmented body, which he termed, after Danilewsky,[3] a vermiculus. This vermiculus moved about the field of blood, penetrating and actually destroying the corpuscles that opposed its progress. MacCallum later also observed the entrance of a flagellum into an extra-corpuscular spherical body of the æstivo-autumnal malarial parasite, although in this case no resulting vermiculus was observed. He interpreted his observations as showing a process of fertilization of the female parasite by the male spermatozoon, or flagellum, with the production of the vermiculus as the result of this sexual conjugation.

Ross[16] later also observed vermiculi in the stomach of a grey mosquito killed within an hour of feeding on a crow infected with halteridium.

Lately, Koch[28, 39]* also claims to have fully confirmed in many cases MacCallum's clever observations in halteridium, and also to have found the vermicule stage of proteosoma in the stomach of infected mosquitoes, though he failed to observe the act of fertilization in proteosoma.

Marchoux † also, in Africa, working with pigeon's blood infected with halteridium, has recently reported his full confirmation of MacCallum's original observations.

Manson,‡ accepting these observations by MacCallum in halteridium, applied them to proteosoma and human malaria, to explain the pigment granules of the coccidia in the mosquito's stomach-wall. Instead of the non-pigmented flagella penetrating the stomach-wall of the mosquito to develop into pigmented coccidia, what was more natural to suppose than that the pigmented, actively motile vermiculus was the penetrating agent? The development of vermiculi from human malarial parasites has never been observed, but their development may be provisionally assumed, and this hypothesis accepted as the best theory of explaining the origin of the pigment granules of the coccidia. §

The brilliant results which Ross had obtained had meanwhile aroused the interest of the Italian investigators and stimulated them to a series of researches, and in the latter part of 1898 and during the present year several important contributions from them have appeared in the journals, each adding new evidence in confirmation of the theory of the inoculation of malaria by mosquitoes, until it is now possible to say that every essential step in the experimental proof of this theory has been obtained, and the theory has been removed from the realm of speculation to that of established fact.

Bignami,[24] of Rome, in August, 1898, began inoculation experiments on healthy men with mosquitoes obtained from malarious localities, but in two such trials failed to infect his human subjects. A possible explanation of his failure he found in the assumption that his mosquitoes were perhaps not a species suitable to act as host to the malarial organism, as Ross had found that only the "grey" mosquito had played the part of host and inoculating agent of proteosoma for birds. His suspicions were further confirmed, he says, by the appearance, while he was still pursuing his investigations, of an important article by Grassi,[20, 33] showing that in Italy and Sicily, where he had investigated the subject, though mosquitoes were abundant in places free from malaria, certain species of mosquitoes were absent from such places and were found only in places where malaria was rife. He found three species of mosquito thus exclusively associated, he thought, with malarious localities, viz., Anopheles claviger Fabr., Culex penicillaris Rondani, and Culex malariæ Grassi, and he assumed that these were the malaria-bearing species of mosquito. Profiting by this advice,* Bignami started anew an experiment on a healthy man with mosquitoes obtained from Maccarese, an intensely malarious place. The subject of the experiment was a man who had been for six years an inmate of the Santo Spiriti Hospital suffering with a chronic nervous affection, and who had never had malaria. The experiment was conducted in a room in this hospital, "where none of the physicians have ever known an autochthonous case of malarial fever to occur, nor has malaria ever been known to originate in any of the neighboring houses." The man slept in a room in which the mosquitoes found at Maccarese were at frequent intervals liberated, and was subjected to their bites from September 26th until the end of the experiment. On November 1st the patient developed a chill and fever, and the temperature continued elevated until after the administration of quinine on November 3d. The blood examination on November 2d was negative, but on November 3d showed numerous hyaline, pigmented, intra-corpuscular, æstivo-autumnal parasites. Specimens of the mosquitoes used in this experiment were identified by Grassi and were found to belong to the three species Anopheles claviger, Culex penicillaris, and Culex malariæ,† species which Grassi had already found, he thought, to be exclusively associated with malarious localities. Thus Bignami had for the first time succeeded in producing malaria experimentally in man by the bites of mosquitoes.

This important success stimulated the Italian investigators to a more vigorous prosecution of this study, and led to a series of investigations and reports, which collectively have placed the inoculation theory on a sound basis of scientific demonstration.

---

* Koch[39] claims to have made these observations prior to the publication of MacCallum's first report, though he fails to state the exact time at which they were made. He acknowledges, however, MacCallum's priority in publication. MacCallum first announced his discovery in a paper read before the British Association for the Advancement of Science, in Toronto, on August 24, 1897; subsequently, also, before the Johns Hopkins Hospital Medical Society, on October 18, 1897.

† "Processus de Reproduction sexuel chez les Hématozoaires du Genre Laverania Grassi et Feletti" (Halteridium Labbé). Comptes rendus hebdomadaires des séances de la Société de Biologie, tome vi., No. 9, March 17, 1899.

‡ Ross[16] first suggested this idea in the following words: "The entry of an entire vermicule of proteosoma into the external coat of the stomach of a gray mosquito and its development there into a pigmented coccidium afford indeed an explanation fascinating in its simplicity."

§ Since the preparation of this paper, Grassi[42], and later also Bastianelli and Bignami[44], have announced the discovery of the vermicule stage of human malarial organisms within the stomach of infected Anopheles.

* Grassi[38] has recently claimed that this third and successful experiment by Bignami was undertaken upon his (Grassi's) express advice as to the species of mosquito to be used, and that it resulted successfully only after he (Grassi) had on October 20, 1898, brought into the experimenting-room some Anopheles claviger. (He claims further that it was he alone who discovered that a fourth species of mosquito, Anopheles superpictus, propagates malaria, and that it was he who concluded that all Italian Anopheles could propagate malaria.)

† From subsequent studies no convincing evidence has been produced to show that these Culex species play any part in the development of malaria.

On December 4, 1898, Bastianelli, Bignami, and Grassi[25] published an article reporting a second successful inoculation experiment, in which they caused a case of double tertian infection in a man previously free from malaria, by the bites of Anopheles claviger. The stomach-wall of these Anopheles claviger on subsequent examination showed the developmental stages (coccidia) of tertian parasites. They also narrate another experiment in which mosquitoes were collected from a room occupied by four people all suffering apparently with æstivo-autumnal malaria. These mosquitoes were found to consist of six Culex pipiens, one Anopheles nigripes, and four Anopheles claviger. Of these eleven mosquitoes, in only two, Anopheles claviger, were they able to find in the stomach-wall developmental forms corresponding to the coccidia described by Ross.

An interesting paper by Grassi and Dionisi[26] appeared in the same journal (December 4th), treating of the biological classification of the various human and animal hæmosporidia, to which it may be well to devote a few lines here, as the biological terms used are being generally employed in articles on malarial parasites.

Considering the question, which of the two hosts of the parasite, the warm-blooded, vertebrate animal, or the invertebrate insect, should be regarded as determinate and which as intermediary host, they concluded that the vertebrate should be considered as the intermediary host and the invertebrate insect as the determinate host. In the intermediary warm-blooded host the parasites develop to maturity, some proceeding to sporulation to continue the life-cycle of the parasite within this host, and others, the extra-cellular, mature forms, being incapable of such sporulation, but being destined to continue the life-cycle of the parasite in the determinate host or insect. These non-sporulating forms are called *gameti*, and exist in two forms, the female macrogameti, which do not become flagellated, and the male microgametocytes, which do develop flagella, when they find the conditions suitable to their development in the stomach of the determinate host or insect. Here the flagella of the microgametocytes become free, and they are called microgameti. They are the male elements, analogous to spermatozoa. They penetrate the female macrogameti in a true sexual process, and as a result the fertilized female macrogameti change their shape, become elongated and motile vermiculi, which penetrate the stomach wall of the insect, there to become encysted, the so-called coccidia. In these encysted parasites sporoblasts develop, and become the sporozoits or germinal threads, which, upon the rupture of the coccidia, are carried to the salivary gland and thence by the bite of the insect back to the intermediary host, to begin again the double cycle of the development of the parasite.

Continuing their work, Grassi, Bignami, and Bastianelli[27]* reported, January 8, 1899, that seventy-five per cent. of Anopheles claviger, caught in rooms that were occupied by people infected with malaria, were found to contain the malarial parasite, while control mosquitoes were negative. They found that an external temperature of 30° C. was best suited to the development of malarial parasites in mosquitoes, while lower temperatures retarded or prevented their development. In Anopheles claviger fed on blood containing ripe crescents, they found the same developmental stages that Ross had described for proteosoma, including the sporozoits in the body-cavity and in the salivary gland and ducts. They also infected Anopheles claviger with tertian blood, and followed the developmental stages of the parasite in the stomach-wall until the fifth day.

On February 5, 1899, these same observers[29] announced that for the first time they had succeeded in infecting Anopheles claviger with quartan blood, from a woman suffering from a severe quartan infection of long standing. Developmental stages of the parasite, corresponding in size to those of the third day after infection with æstivo-autumnal parasites, were found in the stomach-wall.* They reported also a second successful inoculation experiment with tertian organisms. In still another case they allowed three Anopheles claviger, ten days after these mosquitoes had fed on a patient whose blood contained crescents, to bite a healthy person, in whom, after an incubation period of twelve to thirteen days, a severe æstivo-autumnal infection developed. After the mosquitoes had been used for this experiment, they were examined and sporozoits were found in their salivary glands. They also stated that Anopheles pictus was capable of being infected with æstivo-autumnal parasites.

Bastianelli and Bignami[33] reported, in April, 1899, further studies. They made out structural differences between the female macrogameti and the male microgametocytes. In the former the nucleus is large and peripherally placed and contains relatively little chromatin; in the latter the nucleus is placed at the centre of the cell and contains a larger amount of chromatin. In the development of flagella or microgameti from microgametocytes, the rods of chromatin are seen to wander out and to enter into the formation of the flagella. In tertian parasites the number of flagella is usually six or seven, in æstivo-autumnal parasites only four, as a rule. Fertilization of the parasites was never observed by them.

They described also the differences observed in the encysted forms of tertian and æstivo-autumnal parasites in the stomach-wall, differences which were characteristic of the two species, and by attention to which they claimed to be able readily to differentiate the tertian from the æstivo-autumnal encysted or coccidial form. They did not find the dark spores, first described by Ross in proteosoma, in the Anopheles.*

They recorded also three successful inoculation experiments, the first a double tertian infection caused by Anopheles claviger, the second a case of tertian produced by Anopheles claviger (both these cases had been previously recorded briefly), and the third, a very interesting case, as follows: Fifty Anopheles claviger, from Maccarese, were let loose in the sleeping-room of a man already infected with æstivo-autumnal malaria, and whose blood contained crescents. After about eighteen days this man developed a fresh tertian infection, and the æstivo-autumnal parasites disappeared from his blood. Most of the mosquitoes were subsequently found to be infected with crescents. Three of these mosquitoes were later allowed to feed on another man, who after an interval of nine to twelve days developed an æstivo-autumnal infection.

The latest available published reports from Grassi, Bignami, and Bastianelli[34] appeared May 7, 1899. They reported the development of both æstivo-autumnal and tertian parasites in Anopheles bifurcatus, just as in Anopheles claviger, and suggested that the Anopheles bifurcatus is perhaps only a variety of Anopheles nigripes. They thought it would probably be shown that all the Italian species of Anopheles may act as host to the malarial parasites. This rôle in Anopheles pseudo-pictus remained still to be proved. They failed to find sporozoits in the salivary glands of young Anopheles claviger raised from the eggs of adult Anopheles caught in malaria-infected houses, and the bites of these young Anopheles on men proved harmless. (The so-called brown spores obtained from Anopheles were swallowed in considerable number by one of the experimenters with negative results.)

---

* They also described in the cells of the salivary gland certain peculiar bodies which they interpreted as degenerated sporozoits, but in a subsequent paper[34] they withdrew this idea, and stated that these forms were also found in the salivary glands of young uninfected Anopheles claviger, and therefore must be either artifacts or else the normal secretion of the gland cells.

* Since writing this paper, announcement has been made of the observation of all stages of development of the quartan encysted parasite in the stomach-wall of Anopheles.[42, 43, 44]

† They have since[42, 44] observed the "black spores" or "black bodies" in the mature, encysted forms in the stomach wall of Anopheles, and interpret them as "representing probably a product of degeneration of the contents of the sporozoon."

Several papers have appeared during the past year from Koch,[28, 37, 39] confirming, in general, the observations of Ross and the Italian investigators, though in his latest article[37] Koch expresses the belief (for reasons which appear indecisive) that Culex pipiens, in addition to the Anopheles, acts as host to the malarial parasite. Koch has also discovered an intra-corpuscular parasite in the blood of monkeys,[39, 40] which appears very similar to the tertian organism of human malaria.

At the present time, from week to week, reports are appearing in *The Lancet*[41] and the *British Medical Journal*[41] from the malarial expedition, headed by Ross, which was sent to Sierra Leone by the Liverpool School of Tropical Medicine. From these reports it appears that a new species of Anopheles has been found which acts as host to the malarial parasite, and that the quartan parasite was again, as it had been previously by the Italian investigators,[42, 44] found to develop in Anopheles.

From the foregoing summary it is seen that the theory of the inoculation of malaria by mosquitoes (at least certain species of the genus Anopheles) has been thoroughly established and can no longer admit of question. Practically every step of the process has been followed with the tertian and æstivo-autumnal parasites, as well as with proteosoma of birds. The quartan parasite has been followed up to its coccidial stage in mosquitoes, though it has not yet been made to return to its human host by the bite of mosquitoes. The demonstration of this last link in the chain of evidence we may confidently expect.

The question remains whether malarial infection is produced only by the bite of mosquitoes. This cannot be affirmed positively at the present time, but the cumulative evidence tends strongly to support this belief. All experiments hitherto made, and there have been many, to produce malaria experimentally, except by direct subcutaneous or intravenous inoculation and by the bite of the infected mosquito, have resulted negatively. The many attempts to cause malaria by infection through the ground-air and water of malarious regions have been unsuccessful. Even subcutaneous injection of water and dew from the malarious Roman Campagna has proved harmless. The possibility that a resistant spore form of the malarial parasite may be cast abroad by the mosquito, and may subsequently infect man through the air or water, cannot be denied, but the evidence thus far obtained weighs against this hypothesis. Nor is there any evidence that the mosquito may infect its eggs or its young directly or indirectly. Considerable investigation of this possibility has yielded only negative results. The facts thus far determined show only that the malarial parasite is removed from the blood of man by the bite of the female mosquito (the male is not known to bite), develops and reproduces in this same individual mosquito, and by its bite later may be returned to man in the form of spores.

The mosquito theory of malarial inoculation seems to correlate and explain all the various facts that have been observed in relation to the appearance and spread of malaria. The numerous conditions described as favoring or opposing the spread of malaria are found equally to favor or oppose the development, activity, and spread of mosquitoes. I have been able to find only one exception to this generalization, namely, in the asserted fact that, in exploring uninhabited lands, men among whom malaria did not previously exist may develop malaria. If this statement is unreservedly true, and no satisfactory explanation of it is forthcoming, it will require some modification of our present belief, as it seems to show that man is not a necessary host to the malarial parasite. But we must require absolute proof of this claim before we can admit it. There is, of course, a possibility that future investigations may show that the human malarial parasites may develop in other hosts than man and the mosquito.

The discovery of the method by which malaria is carried directs us to the rational means of combating the spread of the disease. The mosquito must be the object of attack. We need not attack all mosquitoes indiscriminately, but only such kinds as are known to act as host to the parasite, or, so far as yet shown, mosquitoes belonging to the genus Anopheles. The commonest house mosquito belongs to the genus Culex, and seems to be harmless. Various other genera of mosquitoes are recognized, but they are uncommon and are not known to be carriers of malaria.

Ross[36] is of the opinion that for practical purposes of attack, we need only to learn to distinguish between Anopheles and Culex, which have certain differential characteristics. A wholesale crusade to exterminate from a given locality the adult mosquito would prove ineffectual, but such an attempt against the eggs and larvæ, he thinks, promises practical results.

The harmless Culex lays its eggs on the surface of any artificial collection of water, such as pots, tubs, cisterns, wells, drains, and ditches, as well as in stagnant pools and ponds in the vicinity usually of houses. The Anopheles, on the contrary, seem to prefer, as a rule, natural collections of water on the outskirts of towns and in rural districts, as a place of deposit for its eggs. It would not be necessary, therefore, in attacking Anopheles to look to every bit of collected water, but rather to the occasional ponds and stagnant pools outside of towns.

According to Ross, the larvæ of Culex are readily distinguished from those of Anopheles by the fact that the former are seen floating head downward on the surface of water, due to the fact that they are provided with a breathing-tube which is inserted in the rear end of the body, whereas the larvæ of Anopheles, which are not so provided, float flat on the surface of the water, like sticks. This difference "enables us to distinguish the grubs at a glance, and therefore the pools in which they breed." The practical importance of this, however, seems to be partly negatived by the fact that this rear-end breathing tube of the larval stage of Culex disappears in the next stage, the pupal stage,[11] and in this stage the Culex floats flat on the surface of the water, a fact of which Ross makes no mention.

It is a surprising fact that comparatively little is known by entomologists in regard to the distribution and habits of the different kinds of mosquitoes, and it is therefore necessary for us largely to develop our knowledge of mosquitoes in this direction.

There are three principal methods of waging a war of extermination against mosquitoes: first, by drainage of the breeding-pools; second, by the introduction of fish into them; and third, by scattering petroleum or other chemicals over them. The first method is well known for its effectiveness; the introduction of fish in the breeding-waters is of value, if they permit the growth of fish, for fish devour and destroy the grubs of mosquitoes; the use of petroleum or other chemical substances on the water has been found to destroy effectually the larvæ and pupæ of mosquitoes. Howard's[4] experiments show that one ounce of petroleum to fifteen square feet of water surface will destroy mosquito grubs and prevent their subsequent development for a considerable period, probably from two to four weeks.

In conclusion I wish to emphasize the fact that every case of malarial disease may be a menace to the public health, provided the Anopheles be also found in the same locality, by acting as a focus of infection for the spread of malaria in the immediate vicinity, and it is probable that the periodical appearance of malaria in regions usually free from it is explained in this way. It follows that cases of active malaria should be isolated by mosquito netting or otherwise, as a preventive of the dissemination of the disease.

OBSERVATIONS ON THE SURGERY OF THE BRAIN, BASED ON CLINICAL AND EXPERIMENTAL EVIDENCE.

By GEORGE W. CRILE, M.D.,

CLEVELAND, OHIO,

PROFESSOR OF CLINICAL SURGERY AND APPLIED ANATOMY, CLEVELAND COLLEGE OF PHYSICIANS AND SURGEONS; SURGEON TO ST. ALEXIS AND CLEVELAND GENERAL HOSPITALS.

Elasticity of the Brain.—Grashey has proved that the cerebral tissue is incompressible. The coefficient of compressibility is even less than that of water. In a series of experiments upon the elasticity of the brain by Horsley and Levy, they concluded that the recoil of the brain, after a given compression, was not at all proportionate to the height of the blood pressure at the time, but to the elasticity of the brain tissue itself. When the brain was subjected to a sudden pressure the recoil occurred within ten to thirty seconds after it, soon recovering its normal level. The recoil, however, was considerably dependent upon the height of the blood pressure.

On the Effect of Increased Intracranial Pressure.—The immediate effect of increased intracranial pressure is not marked until the brain is compressed from five to seven per cent. of its volume. The effect upon respiration is earlier noted and more pronounced than that upon the blood pressure. There is first a slowing of the respiratory rhythm, then arrest. Active expiration is affected, then active inspiration. The amount of pressure necessary to arrest respiration is somewhat dependent upon the height of the blood pressure. The higher the blood pressure the higher the intracranial pressure necessary to produce respiratory arrest. Even after arrest has taken place, if the blood pressure has increased, respiration may be resumed, and in fact the time when respirations will be resumed can often be foretold by noting the rise of the blood pressure. After respiratory arrest had taken place, if the vagi had been previously severed, thus causing a rise in blood pressure, respirations were sometimes renewed. In the presence of arrested respiration, if artificial respirations were produced, a rise in blood pressure usually followed, and the natural respiratory efforts appeared in the midst of the artificial.

The effect of increased intracranial pressure upon the heart was, first, a slowing of its rhythm, with sometimes intermission, then later a complete arrest. If the pressure was continued for a sufficient length of time, the cardio-inhibitory mechanism became exhausted and a very rapid heart action followed.

Pari passu with the increase of intracranial pressure, the blood pressure fell. In some instances there was a mechanical stimulation of the pressor action of the vasomotors, producing a temporary rise in blood pressure. As a rule, when the vagi were severed, allowing a very rapid heart action together with the normal rise of blood pressure attending such section, the application of pressure upon the brain produced an additional rise in the blood pressure which was still more increased by means of artificial respiration.

On the Relation of the Depth of Anæsthesia to the Foregoing Phenomena.—The deeper the anæsthesia the earlier and the more abruptly the respirations failed. Conversely, when the brain was under a considerable pressure, a less amount of anæsthesia was necessary to reduce the animal to the state of so-called surgical anæsthesia, while the effect of the increased pressure of the brain upon the heart and upon the blood pressure was also dependent upon the depth of the anæsthesia. It was not so marked in the case of the respiration.

Clinical.—Since having performed the experiments leading to the foregoing observations, I have had ample clinical opportunities for verifying them. Whenever, as the result of a hemorrhage, an abscess, a depressed fracture, or other cause of increased intracranial pressure, the respiration, or the circulation, or both, are modified by such pressure, it is fair to assume that the brain has been subjected to a compression amounting to about five per cent. of its volume. The exceptions to this deduction would appear in cases in which the pressure is exerted more directly upon the part of the brain representing the functions modified. The elastic recoil of the brain is observed in cases of depression due to hemorrhage on the removal of the clots, on elevating depressed fractures, and on evacuating abscesses. I have seen clinical proofs of the effect of increased intracranial pressure upon the circulation as striking as the experimental. There is scarcely any mistaking the slow, full "pressure" pulse, nor the active inspiratory phase, and finally the whole respiratory action under pressure. The great significance of a rapid pulse alternating with a very slow pulse at comparatively short intervals is obvious. This signifies the dissolution or breakdown of the cardiac centre. When this stage has been reached, there is scarcely a doubt as to the fatal termination. Operative procedures, undertaken under such conditions, are nearly always fatal, as in addition to the foregoing the vasomotor centre is almost invariably exhausted. If the circulation of the skin is studied, it will be found that the vasomotor action is lost, or nearly so, and under no circumstances should an operation then be undertaken. Experimental and clinical evidences are in accord as to the statement that the respiratory centre is far more sensitive than the cardiac centre, and gives an earlier indication of increased intracranial pressure. The expiratory phase of the respiratory act is first affected. In performing an operation upon the brain under the circumstances of an increased intracranial pressure, I usually detail an assistant who is to administer artificial respiration in case of sudden respiratory failure so likely to occur in the administration of an anæsthetic, before the stage of surgical anæsthesia is reached. I also have hot water and pieces of ice at hand, so that the assistant may, in the process of restoring respiration, apply cold alternating with heat upon the abdomen and chest. Ice is a powerful inspiratory stimulant and heat a powerful expiratory stimulant. Thus the alternating of the two extreme temperatures stimulates both sides of the centre. If respirations fail as above indicated, the operation should not be abandoned, but the skull should be opened with as much dispatch as is consistent with safety, the intracranial pressure being relieved by cutting away a sufficient amount of skull, when normal respirations will almost certainly be resumed.

On the Blood Supply of the Brain.—Sherrington and others have been able to demonstrate the presence of vasomotor nerves in the vessels of the brain. It is probable that the cerebral circulation is wholly dependent upon the general blood pressure, and, inasmuch as the general blood pressure is very markedly regulated by the capacious splanchnic area, it is obvious that the cerebral circulation may be better controlled by modifying the blood supply of the splanchnic area than by any attempts at the modification of the cerebral circulation itself. It is true that, as a result of certain drugs, the amount of blood flowing from the veins of the brain is increased, but this increase is due to an increase in the rapidity of the flow through the cerebral arteries and capillaries.

On the Immediate Effect of Traumatisms.—I have been able to demonstrate experimentally that the first effect of a blow upon the skull, of compound fractures, of rapidly increased intraventricular pressure, of gunshot injuries, etc., is respiratory failure. Gunshot wounds in a large proportion of the cases produce sudden respiratory failure. Introducing a needle connected with a pressure bottle raised to a considerable height and containing decinormal salt solution, and allowing the fluid rapidly to fill up the lateral ventricles, caused an almost immediate arrest of respiration. In one gunshot experiment, the animal was killed by a pure respiratory failure, and the ball did not even touch any portion of the brain but passed close to the medulla. This structure was not even touched by the bullet; the circulation was but little affected. The concussion imparted was sufficient to arrest respiration permanently. One of the earlier casualties in the Spanish-American war, in the navy, was that of a gunshot injury of the head. In the report of this case, the surgeon observed that respirations were arrested, but the heart continued to beat for some minutes afterward, and I wish to direct attention to the probable indication for administering artificial respirations as a first aid in brain injuries. It has been demonstrated experimentally and clinically that the respiratory centre is extremely sensitive, and that if artificial respirations are supplied for a time, natural respirations may be resumed. It is well to bear in mind that when respiratory failure does occur, natural respirations will be resumed earlier if blood pressure is increased, so that even though the circulation has not reached a dangerous depression, it should be restored to its normal or even increased on account of the favorable effect upon the respiratory action.

On the Cortical Respiratory Centres.—It is true that electrical or mechanical stimulation of any sensitive nerve may produce a change in the respiratory action, increasing the respiratory tonus, sometimes the respiratory clonus, and nearly always the respiratory rhythm. This occurs under surgical anæsthesia. There is in the dog an area of the cortex corresponding with the upper end of the supra-orbital sulcus, a stimulation of which produces a very marked increase in the respiratory rhythm. The animal, in fact, literally pants. An over-inspiratory clonus is produced by a stimulation of the cortex at the olfactory bulb and tract. A well-defined area for producing arrest of respiration is found on the outer side of the olfactory tract just in front of the junction of the tract with the uncinate. There is in this portion of the cortex a well-defined "arrest" area which, when subjected to electrical stimulation, causes a complete arrest of respiration. The arrest takes place usually in the inspiratory phase of the respiratory act. Now, this area is in relation with the base of the skull, and it rests upon a portion of the skull which is not well protected by the so-called water bed of the brain; therefore, in an injury of the brain in which the brain is thrown forcibly against the base of the skull, this portion is likely to be injured and may produce thereby a respiratory arrest due to a mechanical stimulation and injury of this centre. In a case under my observation, in which a patient in falling struck violently upon the bottom of the hold of a vessel, producing respiratory arrest, causing death in a short time, the autopsy showed that there was marked laceration of the portion of the brain corresponding with the cortical arrest area just described. I am, of course, not certain as to whether the local or the general injury caused the respiratory arrest.

On the Cerebellum.—It has been only within recent years that the physiology of the cerebellum has been fairly well worked out. One of the most striking facts, both clinically and experimentally, regarding the cerebellum, is the remarkable compensation which may take place after injuries and in disease. Luciani and Russell have shown that an animal may live after the ablation of the entire cerebellum. Owing to the remarkable range of compensation, clinically, the absence of characteristic cerebellar symptoms must always be borne in mind. Extensive disease of the cerebellum may exist with but little clinical evidence. The effects of the removal of the lateral lobe of the cerebellum are the following:

(*a*) There is a strabismus, such that the opposite eye is directed downward and outward, while the eye on the same side as the lesion is little, if at all, deviated.

(*b*) The consequent nystagmus is such that the lateral jerks of both globes are directed toward the side of the lesion.

(*c*) The motor phenomena consist of a paresis affecting chiefly the limbs of the same side as the lesion. There is also increased muscular rigidity on the same side as the lesion.

(*d*) There is inco-ordination, so that there are rotation and reeling toward the side opposite the lesion.

(*e*) The sensory phenomena include blunting of sensibility, chiefly of the limbs on the same side as the lesion.

(*f*) The reflexes are markedly increased, chiefly on the same side as the lesion.

There has been much confusion and many differences have arisen among experimenters and clinicians with regard to symptoms. Much of the confusion, in regard to the reeling, may be due to the fact that observers do not adopt the same rule in describing a reeling to the right or to the left, whether it applies to the observer or the observed. Both experimenters and clinicians are agreed as to the marvellous rapidity with which compensation takes place after disturbance of the functions of the cerebellum. This accounts for the destruction of large portions of this organ by the slow development of tumors without producing symptoms, for, inasmuch as the growth is slow, compensation takes place *pari passu* with the development of the tumor, but in cases of hemorrhage or of rapidly developing abscesses the cerebellar symptoms are more pronounced, and the earlier the observations the more clearly will the symptoms present themselves. I have been able to verify on the human subject, in three different instances, while performing operations on the cerebellum, the effect upon the eye of irritation of the cerebellum. In each of these cases I had occasion to explore the lateral lobe of the cerebellum, and in each instance I asked a colleague to watch the effect upon the eyes while exploring the structure of the cerebellum. In each of the cases the opposite eye was immediately deviated outward and resumed its normal position as soon as the irritation ended. In none of the cases was there any effect noted upon the eye after the actual irritation caused by the exploration had ended. From both experimental and clinical experience I regard the cerebellum as being a safe field for exploration, and would not hesitate to extend the operation to any portion of this organ. The cerebellum was formerly supposed to exert an important trophic influence, but this is now known to be untrue. The cerebellum was formerly believed to act as a whole, but it is now known that its division mesially does not interfere with the functions of either half of this organ. While the cerebellum has a crossed action on the brain, it has a direct action on the spinal cord.

On the Technique of Opening the Skull.—I have tried the trephine and the chisel each in a considerable number of cases, and have finally given almost unqualified preference to the chisel. Neither the circulation nor the respiration was appreciably affected while the skull was opened with a chisel and mallet. The observations were made by recording the results on smoked drums. With the use of the mallet and chisel there is a very great range of adaptibility which is not possible with the trephine. I use a very sharp chisel which cuts the bone with the lightest taps of the mallet, cuts it sharply and accurately, enabling the operator to enter the skull in much less time than by the trephine, and enabling him to control the size and shape of the opening. The opening of the skull may be without injury to the brain, either from jarring or from the chisel itself.

After the opening has been made, I prefer the use of a sharp bone forceps to any instrument of special design that I have yet used for the further removal of the skull. The prismatic-shaped, pointed forceps, devised by Mr. Horsley, answers the purpose admirably. The hemorrhage coming from the diploë, while never dangerous on account of its quantity, obscures so much the field of operation that it is important to obviate it. This is easily and readily done by the use of a ten-per-cent. solution of olive oil and beeswax, making a wax of sufficient consistency to press into the cut edges of the bone, instantly stopping local hemorrhage. This wax is harmless and may be allowed to remain.

I wish in conclusion to report a rather remarkable case of the destruction of the so-called "name centre" by a bullet wound. I will allude to it only briefly here, as it will be reported later in detail. The case is one in which a 22-calibre bullet took effect just above Reid's base line on a vertical plane with the anterior border of the ear. The force of the bullet was so far spent in traversing the bone that it was arrested at a depth of seven-eighths of an inch in the substance of the brain in the third inferior temporo-sphenoidal convolution, cutting a circular hole a little less than three-quarters of an inch in diameter and seven-eighths of an inch in depth, the lower margin resting on the base of the skull, the posterior border of the circular wound being in a vertical line with the anterior border of the external auditory meatus. The bone was cut away some distance around the point of entrance and lodgment of the bullet. The bullet was readily removed. No other portion of the brain was injured, neither was there any hemorrhage of consequence. The operation was performed on the eighth day after the injury. The only symptoms manifested were the patient's inability to name common objects. His conception and perception were perfect. Articulation was perfect, and no other function was either modified or destroyed, excepting the ability to speak common names. This case has been thoroughly worked up from every standpoint, and is very definite in pointing out the location of the centre.

The clinical observations upon which this paper is based consist of forty-seven operations on the brain and of a large series of experiments on animals, a part of which has been published, and the greater part is to be published in a later paper, the purpose of this paper being to call attention to the value of placing the experimental and clinical evidence side by side, each reinforcing the other.

SPLENIC EXTRACT AND THE SPLENIC FUNCTION.[1]

By CHARLES RAYMOND CARPENTER, M.D.,
LEAVENWORTH, KANSAS.

GLANDULAR extracts have during the last few years attracted considerable attention in the domain of therapeutics; and it is the opinion of the writer that they are destined to play a rôle in the near future, the importance of which is but slightly appreciated at the present time. The thyroid extract is the best known, and until recently was almost the only one of this class that yielded any definite practical results. There is always danger of any new remedy being pushed into new fields by experimenters, and being lauded by them for effects which further investigation shows were merely incidental. It is certainly to be hoped that the new effects ascribed to thyroid extract in the field of gynæcology will not prove illusory. Its effects in cancer of the uterus have been reported to be astonishing and felicitous, and to hold out the hope at least that this dread condition may at last be met by the physician with a therapeutic weapon which he may wield with some assurance that his efforts will not be wholly in vain.

Still more recently we find the extracts of the parotid and mammary glands being used with similarly astonishing results in the intractable conditions of the ovary and other pelvic organs, which, up to the present time, have been relieved permanently only by total extirpation of those organs.

But the object of this paper is to speak of another extract with which the world is little acquainted, and incidentally to discuss the splenic function in its relation to infectious disease. The extract of the spleen has been made and used experimentally in various ways for a long time, but there is not at the present time any accessible record of its being used with success as a therapeutic agent. It is therefore with unusual pleasure that I make the statement to this society, and to the medical world, that my experience with the splenic extract has demonstrated that along certain lines it has a very decided and important therapeutic action, so important, in fact, that if the future bears out in any degree the promise of my experiments and observations, the use of the splenic extract will become as classical as the use of thyroid extract in myxœdema, or the antitoxin of diphtheria in that disease.

Some two years ago, I was led into a somewhat critical study of the conditions which prevail in typhoid fever, and, like every other physician who has ever given the matter any thought, was impressed with the utter helplessness of the vaunted science of medicine in its presence, so far as curing or aborting the disease was concerned.

"They also serve who only stand and wait," says the poet; and, unsatisfactory as it is, that is about the sum of the physician's services in typhoid fever. We ameliorate the conditions in various well-known ways, and sometimes imagine we have shortened its course, but no candid physician will claim that, with any treatment in general use at the present time, he can cure the disease. I do not say this to the disparagement of any one, but the fact remains that there is no specific treatment known to the profession for this disease. The use of the splenic extract in typhoid fever, however, produces such marked and rapid effects when given as hereafter stated, that when the philosophy of the treatment is considered, it seems to be as near a specific treatment as anything could be, provided time and experience show that these effects are uniform and always to be relied upon. So far, they have been unvarying when the conditions were complied with. Heretofore, when the disease has once declared itself, the patient has been practically turned over to the nurse. Systematic cold bathing, the milk diet, and slightly astringent intestinal antisepsis when the enteric symptoms are marked, have been most relied upon. On the whole, these measures give the best results, mitigate the severity of the symptoms, make the patient more comfortable, and reduce the mortality of the disease more than any other treatment heretofore recognized. I do not say this to the disparagement of Dr. Woodbridge or any one else, but beg to adhere to my opinion. The Brand treatment, when properly administered and accompanied by the milk diet, has been more and more recognized as the best treatment for typhoid fever.

Very well, why do the cold bath and the milk diet do so much for the typhoid-fever patient?

Intestinal antisepsis is well understood; it is unnecessary to dwell upon it here, except to say that, as a fundamental treatment, it has fallen far short of what the medical profession has expected from it, and at present it is not relied upon except as an adjuvant to the Brand treatment. The reason for this is to be found in the steadily increasing list of cases in which the intestinal lesions have been either absent or of trifling extent; and Osler's now famous observation that the intensity of the disease bears no relation to the intensity or extent of the intestinal lesions, is rapidly becoming the opinion of the profession.

But when the question is asked of almost any body of physicians, "Why does the cold bath produce its well-known beneficial effects in typhoid fever?" almost every one will respond unhesitatingly, "Because it reduces the temperature."

I beg to answer, "Not at all." To be sure it does reduce the temperature, but so do many other remedies which accomplish no good whatever, and do not mitigate the condition of the patient a particle. Quinine reduces the temperature unerringly and without a break until it reaches the normal, or even a point much below the normal; but what good does it do? None whatever. Acetanilid, phenacetin, and the whole list of the coal-tar series will do the same; but we all know that while some slight mitigation of the symptoms occurs, provided the heart is properly supported, it is much less marked than that which follows the Brand treatment.

---

[1] Read before the Leavenworth City and County Medical Society.

Manifestly, then, the cold bath does something, produces in the physical economy some change in addition to the reduction of temperature which these other remedies do not and cannot produce. What is that change?

The only satisfactory answer to this question is to be found in a study of the conditions of the blood in typhoid fever as compared with the blood in the normal condition. Normally the blood contains from five to five and a half million red corpuscles, and about seventy-five hundred white corpuscles to the cubic millimetre. These numbers vary widely, however, in both health and disease. In certain physiological conditions, such as pregnancy and normal digestion, the relative number of white corpuscles or leucocytes is markedly and constantly increased. We find also that in nearly all inflammatory and infectious diseases there is a constant tendency to a similar increase of the leucocytes, or leucocytosis as it is called. Careful observation also shows that with the exception of a temporary decrease at the very beginning of the disease there is a constant ratio between the degree of leucocytosis and the severity of the disease. A mild disease with vigorous vital resistance will be accompanied by a marked leucocytosis; a more severe disease with good resistance, by a more marked leucocytosis; and a still more severe disease with still good resistance, by a still more marked leucocytosis. But, in a very severe disease, with lethal tendencies, we find leucocytosis absent (Cabot).

Now, what does all this mean?

The principle of phagocytosis enunciated by Metchnikoff is still under the searchlight of scientific investigation; different observers differ more or less as to whether the bactericidal action of the blood is due more to the vital action of the leucocytes themselves, or to a direct chemical action taking place in the blood serum. But investigation brings to light only more evidence that the blood does possess a bactericidal action, and whether or not this action is entirely due to the vital action of the leucocytes, the degree of leucocytosis is a fairly accurate index of the bactericidal power of the blood, and hence is an index also of the body's vital resistance to disease. This is an argument directly in favor of Metchnikoff's position, and since he and other observers have watched the actual process under the microscope, there can be no doubt that the leucocytes exercise a directly germicidal effect upon the invading germs.

We have here, then, an explanation of the leucocytosis found in so many diseases, increasing with the severity of the disease. The proliferating glandular system throws into the circulation, as it were, an opposing army to the invading host of the enemy. The more numerous the invading army of germs, and the more vicious their assault, the more numerous the defensive army necessary to meet them and hold them in check. But if the attack is so severe or is made in such a manner that the body's reserve forces cannot be called forth, the defence is a failure; leucocytosis does not take place and the disease at once assumes a grave if not a lethal aspect.

This seems to be true of most diseases; but there is a certain class of grave diseases that seem to be notable exceptions to this rule—that is, they are exceptional in that at no time is there any tendency to leucocytosis, except in the initial stage, or in case of some complication of an inflammatory character, or other condition such as hemorrhage when there is always a tendency to leucocytosis. But such a leucocytosis is incidental to the complication, and seems to have no good effect on the primary disease.

One of these diseases is typhoid fever. In the initial stage we find a very transient leucocytosis, and then begins a steady gradual diminution of the leucocytes from the normal number down to one or two thousand in some cases.

Again we ask, Why is this? Why, in a disease in which the body so much needs the help of its defensive army, does it fail even to put in an appearance? Unless we may construe the initial increase of leucocytes, transient as it is, to be a loyal effort on their part to do their duty; an effort which is quickly throttled by the disease. Is it not because the very citadel of the body where this defensive army is garrisoned, as it were, is besieged?

Whence comes this army of leucocytes?

We have intimated in a general way that the glandular system throws them into the circulation. Physiologists have not entirely determined the extent to which the different portions of the glandular system take part in the production of the leucocytes, but it is admitted by all that they are probably elaborated most largely in that great vascular gland, the spleen. An enormous amount of blood passes through this organ, and it has been shown that blood taken from the splenic vein is very rich in leucocytes, while that taken from the artery is not more so than blood taken from any other artery. This shows that leucocytes are produced in the spleen, and this flood of leucocytes passes from the splenic directly into the great portal vein, through the liver and into the general circulation.

In 1895 F. Bezançon delivered a thesis in Paris, in which he gave an exhaustive study of the spleen, and arrived at the conclusion that it exercised the function of elaborating the leucocytes and also acted as a defensive organ against disease.

We admit, then, that the spleen is the great laboratory in which the leucocytes are produced, although it must be admitted that they are produced also by the lymphatic glands; and we admit that it is from the spleen principally that they are ejected into the circulation when leucocytosis is produced. One of the constant features of the typhoid-fever autopsy is a softened, friable, and frequently enlarged spleen. In severe cases it is sometimes found after death in a totally disorganized condition. In other words, the citadel which should furnish to the body its defensive army has been captured and destroyed by the enemy. Or, to speak anatomically, the organ upon which the body must depend for its defence against disease is a more or less disorganized wreck, incapable of performing its vital function of producing leucocytosis. Now, correlate these facts and let us see what we have:

1. The white blood corpuscles or leucocytes constitute the body's defensive army against disease.
2. The spleen is the great laboratory in which the leucocytes are produced, and from which they are thrown into the blood through the portal circulation.
3. In typhoid fever there is an absence of leucocytosis during life, and a more or less diseased or disorganized spleen found after death.

Do not these facts point directly to the conclusion that the spleen is the vital point of attack in typhoid fever? Is it not reasonable to argue that the method of attack is to inhibit first and finally to destroy the vital function of the spleen of producing leucocytosis? And is not this destruction of function accomplished by a direct action of the germs or their toxin upon the organic structure of the spleen, producing progressive softening and ultimate breaking down of its substance?

As has been seen, while the intestinal symptoms have been so characteristic of typhoid fever as to mislead the whole medical world as to the etiology of the disease, and to give it the name "enteric fever," they are by no means constant; and many fatal cases have been recorded in which no intestinal ulceration was found. Many observers claim that the Eberth bacillus does not produce pus, and that suppuration, when it does take place, in Peyer's patches, the kidney, the liver, or anywhere else, is due to secondary infection from the staphylococcus pyogenes aureus or the streptococcus. Notwithstanding the presence of the bacillus in large numbers in the spleen, the formation of pus in that organ, so far as I know, is unknown; and all of the organs or glands where pus is known to form, and where ulceration or sloughing does take place, are more or less accessible to the pus forming cocci. Particularly is this true of the intestinal glands. The spleen on the other hand is a ductless gland, accessible only through the circulation, hence we have no suppuration there; but the suppression of the splenic function seems to work some change in, and render vulnerable all organs and glands that are accessible through their ducts to the pus-forming cocci. The intestinal glands being most accessible, and for some reason in this condition most sensitive, suffer most. With this elucidation of the pathological anatomy of the disease which has so long been overlooked or misconstrued, we are prepared to answer the question asked above, "Why do the cold bath and the milk diet do so much for a typhoid-fever patient?"

The experiments of Winternitz and Thayer in 1893 showed that the cold bath in health and disease produced, in the peripheral circulation at least, leucocytosis. The former detailed his observations to the Imperial Royal Medical Society of Vienna in February of that year, and Dr. Thayer in April of the same year reported in the *Johns Hopkins Medical Bulletin* twenty cases of typhoid fever in which an average of 7,724 leucocytes were counted before a cold bath, and 13,170 after the bath; an increase of nearly one hundred per cent. Cabot says, in his excellent work on the blood, in summing up the evidence on this subject, "Violent exercise, massage, and short cold baths have been shown to cause a temporary increase in the number of leucocytes in the peripheral blood, all varieties of the cell being represented." Prolonged cold baths, on the other hand, have been shown to produce the opposite effect. But Cabot follows his remark with the observation that "the explanation usually given is that the blood is concentrated by vasomotor contraction and rise of blood pressure"; intimating that the increase in the number of leucocytes is not real but only apparent. To this opinion I beg to offer the objection that it is illogical. By way of argument, take an example: Suppose you have a hollow rubber ball with a small hole in it, filled with blood, which we will suppose you have the power to preserve at the body temperature, in a normal fluid condition. Suppose you make a microscopical count of the leucocytes in this blood per cubic millimetre, and then squeeze out half or two thirds of the contents of the ball and make another count. Does any one suppose for a moment that the second count would differ from the first? Certainly not; and there is absolutely no more reason for supposing that any amount of vasomotor contraction could in itself change the count of the leucocytes in the blood. If there is an increase in the number of leucocytes in the blood after a cold bath, it must in the nature of things be a true leucocytosis, and this we submit is exactly the reason that the uniformly beneficial effects ensue which are always observed when the bath is properly given. It would be idle to expect beneficial effects from a leucocytosis that was only apparent, and in which there was no actual proliferation of the white cells; but it is reasonable to expect benefit when the leucocytosis is real and marked.

If this be true, have we not arrived at the point when we can justly say that any remedy which will produce a true leucocytosis in typhoid fever will be likely to produce at the same time an amelioration of the symptoms and a tendency to recovery? It seems to me we have.

A large number of experiments have been carried on with a view to showing what substances when taken into the body produce leucocytosis and what do not. Pohl showed, in 1889, that most of the so-called tonics and stomachics produce slight leucocytosis; and that iron, quinine, caffeine, and alcohol do not. Von Limbeck and Binz procured the same condition—that is, leucocytosis—by the administration of oil of peppermint, oil of anise seed, and camphor. Löwit experimented with a number of important organic compounds such as blood serum, peptone, pepsin, nucleinic acid, and nuclein, giving them subcutaneously or intravenously, and all of those mentioned produced leucocytosis.

In the light of our previous study of the blood, what do we learn from these experiments?

Quinine, iron, and alcohol do not produce leucocytosis; and they have all been dropped from the list of remedies likely to be of benefit in typhoid fever. Oil of peppermint and camphor produce leucocytosis, and the latter especially has been lauded as a remedy in typhoid fever, while the former has long been known as a powerful germicide, and I have myself used it with benefit in typhoid in the shape of its camphor, menthol.

Nuclein, again, is found in greater or less abundance in milk; and the milk diet is a part of the classical treatment for typhoid fever. The nuclein promotes leucocytosis, according to Löwit and others, and the watery portion of the milk supplies directly the vast amount of the watery portion of the blood eliminated and lost by high temperature and diarrhœa. When we remember that not a little of the restlessness, delirium, and general distress that exist during high temperature and diarrhœa is due directly to a condensation of the blood, and that in such patients the sensation of thirst is obtunded so that they do not call for a corresponding amount of water, we can understand how the regular supply of fluid obtained through the medium of a milk diet properly administered would mitigate this condition.

A vast number of substances have been experimented with, and almost without exception those substances which have been used with benefit in typhoid fever have been shown to produce leucocytosis; and those which do not produce leucocytosis have failed to be of benefit in that disease.

So we find that in 1893 Goldschneider and Jacob experimented with the various organic extracts, and found that extracts of the spleen, marrow, and thymus gland produced decided leucocytosis; while extracts of the pancreas, thyroid gland, kidney, and liver had no such effect.

Here we have a most pregnant fact.

The extract of the spleen produces leucocytosis. In typhoid fever the organic structure of the spleen is attacked; the vital function is impaired; and leucocytosis is absent. Without any other argument, what we have seen from the above experiments ought to lead us directly to the conclusion that the splenic extract would be of benefit in typhoid fever; but there is still another reason. Observation has shown that when the functions of the thyroid gland, the ovary, the testicle, or the spinal cord are impaired, the therapeutic administration of the extracts of those organs supplies the deficiency. Why not expect the same in the case of the spleen?

In 1898 two Frenchmen, Drs. Lépine and Lyonnet, detailed in the *Revue de Médecine* some experiments upon dogs, in which they injected intravenously a solution of the typhoid toxin. Among other things they noted that in such dogs if the spleen was heated, which increased its vitality, the dog revived from a dose that was otherwise fatal. Does not this show that the spleen, when artificially stimulated to exercise its function, resists the typhoid toxin? Why, then, should we not expect therapeutic action from the administration of the extract of the spleen?

In the early part of my studies, relating to the action of glandular extracts and the production of leucocytosis, I attributed this action to the nuclein contained in those extracts. But if the experiments of Goldschneider and Jacob are to be relied upon, the thyroid extract does not produce leucocytosis, although it contains relatively a large amount of nuclein. Other observers claim that it does produce leucocytosis; so the truth probably is that it produces some leucocytosis, but not a marked degree. But the splenic extract does produce marked leucocytosis, and when administered in typhoid fever in doses of gr. v. three times a day, rapidly and steadily reduces the temperature, without undue diaphoresis, ameliorates all the symptoms, and steadily and quickly restores the patient to the normal condition.

Such effects cannot be explained simply by the fact that the splenic extract contains a certain amount of nuclein; for it contains not any more, and some observers say much less than thyroid extract, which produces little or no leucocytosis. Not only this, but in one case in which I administered thyroid extract in typhoid fever, the effect was only a very slight reduction of temperature, and little or no effect was produced on the general condition. As I was out of the splenic extract at the time, I tried then to fill up the gap with parotid extract, but its effects were equally inconclusive, and I was obliged to come back to the splenic extract as soon as it was available in order to produce decided effects. We must therefore conclude that the splenic extract has a specific action entirely apart from the nuclein it contains; and its action in typhoid fever is so marked and so beneficial in its character that, although it has been used in less than half a dozen cases, it is impossible not to recognize it as a powerful and important means of controlling the disease. Indeed it is absolutely the only remedy known to the medical profession at the present time for which we can, with any reason, make the claim that it cures the disease. A recent article advocating the use of nuclein and protonuclein in typhoid fever distinctly admits that it does not shorten the disease or save any time for the patient. I wish as distinctly to assert that in my hands the splenic extract has shortened the disease in a most obvious manner, and reduced the period of convalescence to almost nothing. I wish also to make the statement that it is my belief that any uncomplicated case of typhoid fever may be aborted by the use of the splenic extract as I shall indicate. I do not know that any ordinary complication would furnish any obstacle to the treatment; indeed I know that malarial fever, which is the most frequent complication we meet with in this climate, furnishes no obstacle at all, as I have myself proved several times. Malarial fever indeed is one of the class of diseases in which leucocytosis is absent; and in which, therefore, the splenic extract is indicated, even if we did not know that an enlarged and evidently disordered spleen has from time immemorial been recognized as characteristic of malarial fever.

There is, however, one thing to be observed in the administration of this remedy, and that is, that its best effects are not produced if the percentage of hæmoglobin or the number of the red cells is much reduced. No matter how much the leucocytes are multiplied in number, unless the red cells and the hæmoglobin are kept up, the leucocytes lack defensive power. Indeed if we keep on multiplying the leucocytes under these conditions, we simply produce a condition of leukæmia, which is no improvement on the previous condition. This is easily understood when we remember that the leucocytes are produced in the spleen at the expense of the red cells. Whether the red cells which have arrived at an appropriate age and condition are entirely destroyed in the spleen, and the white cells are builded anew from the elements that previously entered into the composition of the red cells; or whether the Malpighian corpuscles have the power of selecting certain of the red cells of appropriate age and condition and elaborating them in some way to endow them with the vital characteristics of the leucocyte, while the rest of the red cells pass through unchanged, is a matter that further and closer study must determine. But, at any rate, the therapeutic action of the splenic extract under circumstances such as have been cited leaves no room to doubt, if there was doubt before, that the leucocytes are created at the expense of the red cells; and practically we may not disregard the therapeutic hint thus given. Hence, whenever I have had a case of this character, in which the splenic extract did not seem to act promptly, and the percentage of hæmoglobin was evidently deficient, it has been my custom to administer alternately with the extract one of the many excellent hæmatinic preparations on the market, and have always had the pleasure of seeing the characteristic effects of the extract begin to show themselves at once, and the patient quickly on the road to recovery. Theoretically it has seemed to me that a preparation or extract of the red bone marrow would fulfil the conditions here better than any other preparation, but as no stable preparation of this substance has yet come into my hands, I have not been able to carry out the theory.

As previously remarked, I have no long list of cases to report in connection with this paper; but the treatment is so simple and harmless in its character that there is absolutely no excuse for not trying it if you have an appropriate case. If the treatment cannot stand upon its own merits, it should not stand at all, and no report of cases will make it stand.

To recapitulate the treatment more precisely, when I make the diagnosis of typhoid fever, if the enteric symptoms are at all marked, I order the milk diet; and if the temperature is 104° to 105° F., and has persistently stayed at those figures, I order splenic extract gr. v. every three hours for the first twenty-four hours. By the end of the first twenty-four hours the temperature has dropped steadily to 102° or 103°. Then the extract is given in doses of gr. v. three times a day. If the hæmoglobin is deficient by actual test, or if the patient is anæmic in appearance, or whether he is or not, if the extract does not act promptly, I give a hæmatinic three times a day in addition. The temperature will oscillate up and down for a few days, but each oscillation bringing it lower, until in from four to seven days it will be normal and remain at that point. The period of convalescence will depend entirely upon the extent of the lesions produced by the disease before the splenic treatment was begun. If the diagnosis was made early, it will be *nil;* if made after extensive intestinal lesions have been produced, necessarily those lesions must heal after the disease has been checked, and the time necessary for the healing will be in proportion to the reconstructive power of the individual. But the time will be reduced to the minimum by continuing the hæmatinic treatment. After the functional activity of the spleen has been once restored by the destruction of the bacilli and their toxin it is no longer necessary to give the extract, but as long as the supply of hæmoglobin is kept up the spleen will effectively do its own work of reconstructing the leucocytes, which, in the period of convalescence, have ceased to be warriors and become peaceful laborers busily engaged in building up the physical economy weakened by the vanquished enemy.

Before I close I desire to say that the therapeutic principles here enunciated, in my opinion, will be found applicable to other diseases besides typhoid fever. I have myself found them very useful in malarial fever, and it is a question with me whether they do not apply in a greater or less degree to all that important class of grave diseases in which leucocytosis is either absent or ineffective. This class includes at present, as enumerated by Cabot, typhoid fever, malarial fever, influenza (most cases), measles, rötheln, and tuberculosis in all its forms. If only the first two and the last are found amenable to this treatment, the good accomplished by it would be simply incalculable. In tuberculosis I have had no opportunity to try the treatment, but it seems likely to me that, inasmuch as the lymphatic glands are so largely affected in this disease, it will be necessary to combine with the splenic extract an extract of the lymphatic glands. If, in conjunction with these, an extract of the red bone marrow is given or some easily assimilated hæmatinic, I firmly believe that the dread disease consumption, which has for ages been, and is to-day, the great scourge of the human race, would be robbed of its terrors. Unfortunately, for some reason I have seldom had a case of this disease in my practice, and so have had no opportunity to test the treatment of it.

There are two other grave diseases in which I should like to see the splenic treatment tried, although scientific investigation has not yet decided whether or not leucocytosis is absent. Some observers say one thing and some another, but most of them say nothing. I refer to cerebro-spinal meningitis and yellow fever. I have myself used the splenic extract in one case of cerebro-spinal meningitis, and the patient recovered with wonderful rapidity from a condition which at first seemed hopeless; but I used at the same time guaiacol, painted on the back of the neck and head, and I was unable to determine whether the good effect was due to one or the other or to both combined.

Observers differ also as to whether yellow fever belongs to this class. Jones, of New Orleans, found in a study of yellow-fever blood some diminution of the red cells, and profound changes in their appearance and character, but says nothing about the white cells. But when the red cells are so profoundly affected, it is impossible that leucocytosis, even if present, should be effective in resisting the disease. Hence it is my belief that the splenic extract with some good hæmatinic would prove effective in this dread disease. During the outbreak of yellow fever at the Soldiers' Home at Fortress Monroe this last summer, I suggested to Surgeon-General Sternberg the use of splenic extract, and was informed that my communication had been received, but I have no reason to believe that any further attention was given to the matter. If there is anything in this study of the blood and the splenic function, and I have reason to believe there is, it is only reasonable to expect that the use of the splenic extract in yellow fever, with some remedy to build up the hæmoglobin and red cells, would be found directly curative.

In fact, when one looks down the vista of possibilities which lie beyond the veil which we are just lifting in this study of the vital conditions of the blood and the splenic function, it seems as though we were approaching a wonderland in medicine and therapeutics where we may expect to meet with marvels of the very existence of which we had not dreamed.

Physiology of the Pharynx.—In an elaborate article C. Chauveau passes in review the deglutitory, phonatory, secretory, and protective functions of the pharynx. The article is chiefly historical and especially valuable from its extensive bibliography.—*Ann. des Mal. de l'Oreille, du Larynx, etc.*, Dec., 1899.

A Rare and Interesting Bullet Wound; the Bullet Splitting in Halves, as Shown by the Skiagraph.—Angus McLean reports this case, in which the bullet must have been nearing the end of its flight when it struck the humerus, probably at a downward angle, and divided itself over its margin.—*The Medical Age*, January 25, 1900.

Early Intubation in Laryngeal Diphtheria.—William E. Lower reviews his experience, and finds that in no small percentage death is due to obstruction. The advantages of early intubation are that the child is then stronger, the time for wearing the tube is shortened, and hence the amount of nourishment required is less, and less opportunity is given for the introduction of foreign matter into the trachea, diminishing the chances of septic pneumonia. Intubation should be done when the breathing becomes labored, not waiting for the cyanotic stage.—*The Cleveland Medical Gazette*, January, 1900.

Arterial Tension in Childhood.—H. L. K. Shaw calls attention to the lack of knowledge upon this subject, and describes a new and simple apparatus which easily affords the desired information. It is found that in anæmia the blood pressure is slightly raised above normal. In acute endocarditis it is somewhat depressed. In acute nephritis the increased tension so constant in adults does not appear so marked in children. In diphtheria with cyanosis and dyspnœa, with or without intubation, pressure is increased. Tension is not influenced in diphtheria cases without laryngeal complications.—*Albany Medical Annals*, February, 1900.

A New Method of Treatment of Carcinoma Œsophagi.—W. Zweig describes the plan suggested by Rosenheim, which is as follows: The œsophagus is first washed down to the point of stricture with not more than 150 gm. of water. Then 50 gm. of olive oil is poured in and the tube is taken out during the act of pouring, so as to coat over the mucosa with the oil. Eucaine (four per cent.) may be used instead of oil. After a few minutes the patient can eat solid food without much trouble, and the manœuvre can be repeated several times daily. The advantage is the moral effect on the patient: he believes he can eat. Increased ingesta delay the onset of cachexia, and the time is prolonged before the inevitable gastrotomia.—*Albany Medical Annals*, February, 1900.

Croupous Pneumonia in Children.—J. Park West says about one-third of the pneumonia in childhood is of the croupous variety. It is, as a rule, a primary disease, often beginning by vomiting, more rarely by convulsions, and still less frequently by chill. Frequently the signs cannot be made out until the second or third day, and may be absent altogether. One of the important signs is a perverted pulse-respiration ratio. In health there are about ten respirations to thirty-five pulse beats, while here there may be ten respirations to twenty beats. The left lower lobe is most frequently affected next the right apex. The crepitant râle is oftener absent than present. He considers the gastric, cerebral, and migratory types, and differentiates from bronchitis, pleurisy, and broncho-pneumonia. Under treatment, he says, poultices have here no place. There is no routine treatment, and often no drugs are called for—a small quantity of whiskey and weakened milk are the preferable foods. In depression following the crisis, nitroglycerin frequently repeated is very valuable. For the fever nothing meets the indications as well as the bath of 95° to 100° F., with gentle rubbing for ten minutes, repeated as needed. Rarely one or two cooler or cold baths will be required.—*The Cleveland Medical Gazette*, January, 1900.

OVER-PRESSURE THE BANE OF MODERN EDUCATION.

THE harm done to children by the present methods of education is too real to be ignored. The conditions of civilized life have so completely changed within the past half-century that it becomes daily more and more evident that measures must be taken to meet the new situation and to endeavor to propagate and raise a race better fitted to withstand the strain of modern existence. When children were brought up in the country, spending the greater part of their time in the fresh, open air, considerations as to physical development did not enter into the question. The environment being healthy, and food plentiful and nutritious, the natural sequence was that the human product grew up hardy and robust, well equipped for the battle of life. The ever-increasing tendency to desert the country for the town has placed a fresh problem before our scientific men and sanitarians. Children are born and pass their youth amid unhealthy surroundings, in many instances improperly and irregularly fed. In addition to these serious disadvantages they are still further handicapped by the undue stress of school life. The sole aim of modern education would seem to consist in the attempt to develop the mind at the expense of the body. The necessity of exercise and fresh air as a part of a child's training is strangely overlooked. Mental and physical education should go hand-in-hand. Wherever possible playgrounds of ample scope should be attached to schools, and, above all, young children should never be expected to work longer than two hours at a stretch.

Dr. J. S. Lankford, of San Antonio, Tex., read at the annual meeting of the Western Texas Medical Society, held in October, 1899, a paper dealing with the evils of present methods of education. Among other home truths to which he gave expression were: "What shall we say of the death-dealing mental burdens placed upon our children? We impart to the child by heredity and example an ambition to know everything, or if he doesn't happen to have that ambition, we proceed to hammer everything into him. We reach out eagerly to grasp and incorporate all the affairs of the universe in our course of instruction. Regardless of aptitude or natural tendency of mind we group the pupils in enormous classes and give them all just the same. . . . The burden is too heavy, and just as sure as effect follows cause in natural law, our generation of children is being weakened and unbalanced, and a still weaker generation will follow. Our great public-school system, designed to bless the nation, will become a national curse. This is not a false alarm or an idle prophecy. Visit the schools and see the careworn teachers, always working beyond nature's reasonable limits, and you can better understand why she or he seeks your aid before the middle of the term in order to be able to continue work. And here in this broken-down condition of the teacher we see an index to the heavy course and wrong classification."

The health of the young is a matter of vital importance to a nation. As with individuals, so it is with races in the struggle for predominance, the weakest will go to the wall. To insure the physical and mental well-being of the rising generation considerable modifications in our existing system of education will be necessary. Physical culture is not inconsistent with mental culture, and when this significant fact is thoroughly grasped by our boards of education, the present faulty methods of training the young will be changed to those more in harmony with the laws of nature.

COMPENSATORY PROCESSES IN DISEASE.

WERE not the animal organism endowed with structure and function in excess of its ordinary needs, disease would obviously be wellnigh universal. Nature has, however, been almost prodigal in this respect, so that destruction of tissue in one situation or loss of function in one organ may be compensated for, in whole or in part, by a readjustment to the new conditions. This result may be brought about in one or more of three ways, as is pointed out by Leube (*Deutsches Archiv für klinische Medicin*, 66 B., p. 80): (1) Portions of a diseased organ may remain healthy, and this residuum may assume the increased function; or one of azygous organs, as for instance the kidneys, may take up the work of the other, if this be diseased or otherwise incapacitated. This form of compensation is illustrated by the hypertrophy of the heart that takes place when the circulation is in any way obstructed, by the hypertrophy of the muscular coat of the stomach when obstruction to the movement of its contents exists, and by the transformation of yellow into red bone-marrow in the presence of anæmic states.

(2) One set of organs or tissues may perform the functions of another set of organs or tissues having a like action. Such reciprocity of function exists, for instance, between the skin and the kidneys, the stomach and the intestine, the spleen and the lymphatic glands. A distinctly reciprocal relation exists between the action of the kidneys and that of the skin, as pertains to both water and solids, and this fact is often availed of in the treatment of nephritis. Only in the presence of marked cutaneous œdema does Leube consider sweating as contraindicated, as the excrementitious matters left behind by the escape of

the fluid may be absorbed and thus give rise to toxic symptoms. Instead, he recommends multiple capillary puncture of the skin. The salivary glands and the bronchial mucous membrane are also capable in some degree of assuming the functions of the kidneys, and the gastro-intestinal tract also, but only in very small degree. There is abundant evidence that the intestines are fully capable of replacing the activity of the stomach if this be diminished or abolished from any cause. A mutually reciprocal relation exists between the blood-forming organs: the bone-marrow, the lymphatic glands, and the spleen. In cases of profound anæmia and in the sequence of profuse hemorrhage, evidence of increased hæmogenesis in the bone-marrow becomes appreciable from the change in color from yellow to red, and in the presence of nucleated red corpuscles. The spleen at times undergoes hyperplasia under such conditions, and is often found enlarged. Leube has observed such enlargement in a considerable proportion of cases of chlorosis, and these cases have pursued a more favorable course than those unattended with splenic enlargement. With regard to the white blood-cells, the spleen and the lymphatic glands appear to be concerned especially in the production of lymphocytes, and the bone-marrow principally in that of the granular and amœboid leucocytes. Following splenectomy the lymphatic glands become enlarged, and the number of lymphocytes in the blood becomes increased.

(3) Organs and tissues may assume the functions of other organs and tissues having a different action. Of this fact application is made therapeutically, diuresis, diaphoresis, and catharsis often being induced with the objeet of causing absorption of exudates. Having observed rapid disappearance of an accumulation of fluid in the abdominal cavity in the sequence of salivation occurring spontaneously, Leube suggests that at times ptyalism might be induced artificially with the same object in view, and he reports four of five cases of pleurisy with effusion and one of two cases of ascites in which rapid absorption of the fluid took place in connection with profuse salivation excited by the chewing of gum.

MARINE-HOSPITAL SERVICE REPORT.

The surgeon-general of the Marine-Hospital service has recently issued his report for the year ending June 30, 1899, which contains matter of general and special interest. The service now owns and operates twenty-two marine hospitals, and there are besides one hundred and seven stations where patients receive hospital or dispensary treatment. The statement is made that during the fiscal year 1899 the total number of patients was 55,489, of which number 12,610 were treated in hospital. A sanatorium has been established for the use of consumptive patients of the Marine-Hospital service at Fort Stanton, New Mexico, the abandoned military reservation at that place having been handed over by the government for that purpose. The surgeon-general again dwells upon the need of a marine hospital for the port of New York, pointing out that the present arrangement for the care of sick and disabled seamen is unsatisfactory and unworthy of the principal port of the United States. Many useful scientific investigations have been carried out in the hygienic laboratory during the past year, notably those in connection with the pollution of the Potomac River water, and car sanitation. The experiments with regard to the immunization of a horse against typhoid are said to have been progressing satisfactorily, and the value of the serum obtained from the animal is now being tested.

Of course the national quarantine service is the most important department of the Marine-Hospital service, and from the report it will be gathered that on the whole this branch is in good working order. At the various stations 3,838 vessels were inspected and 370 disinfected during the fiscal year. The regulations enforced for the suppression of yellow fever had the desired effect, and it was chiefly due to the arduous labors of the Marine-Hospital service that the disease was kept so well under control. In January, 1899, the maritime quarantine of Cuba and Puerto Rico was transferred to the Marine-Hospital service, which naturally has largely increased the duties of the department. At the present time there are some thirty officers of the service in Cuba and seven in Puerto Rico. Valuable investigations with regard to the cause of yellow fever have been made by a commission of medical officers of the Marine-Hospital service, who have delivered a report on the subject. They verify the findings of Sanarelli in his discovery of the bacillus icteroides, and further demonstrate that this disease is received into the human system through the respiratory tract, holding out hopes that a protective and curative serum may shortly be discovered. At the same time attention is drawn to the fact that sanitation plays an essential rôle in checking the prevalence of the malady. Every effort is being put forth to safeguard America against an incursion of the plague, but the surgeon-general regrets that the bills introduced into the Senate and House of Representatives with the object of strengthening the national quarantine failed to pass.

The Marine-Hospital service has now been in existence for one hundred and one years, but the lapse of time has only served to exhibit in a more and more decided manner the value of its work.

SANATORIA FOR SAILORS.

At a meeting of St. John's, New Brunswick, Medical Society, held at that place in June, 1898, Dr. J. E. March, a Canadian quarantine officer, read a paper entitled "Tuberculosis and the Forecastle," in which he expressed his opinions regarding the measures to be taken with cases of tuberculosis occurring among sailors on shipboard. There has been for some time much discussion on the subject, so that views of experts are especially welcome.

The author of the paper in question, after alluding to the circumstance that tuberculosis is a disease to which seamen in a general way are particularly liable, points out that their mode of life is peculiarly calculated to spread the malady, and quotes numerous instances in which the unavoidable proximity of the crew would appear to have been by far the most potent if not the sole factor in disseminating the germs of infection. Attention is drawn to the undoubted truth that the older the ship the greater the chance of her having become infected. But the subsequent suggestion possesses the merit of novelty, namely, that owing to the presence of a quantity of wet cloth in the forecastle, and taking into consideration the fact that the bacillus not only lives but multiplies and flourishes on the surface of wet cloth, many forecastles are therefore necessarily infected with the bacillus tuberculosis. This theory sounds plausible, and is decidedly worthy of notice. The situation to be faced is consequently this, that consumption is a prevalent disease with sailors, chiefly owing to their manner of life, which is highly conducive to the fostering and spread of the disease. What, then, is the remedy? Dr. March's panacea for, or rather palliative of, the evil is that tuberculosis should be scheduled as a quarantinable disease.

The MEDICAL RECORD, always allowing that it has been demonstrated beyond a doubt that tuberculosis is under certain conditions communicable, at the same time has taken somewhat conservative views as to the degree and scope of its infectivity. We know now that the spread of tuberculosis is to be largely attributed to the inhalation of dried sputum distributed in the atmosphere of houses and rooms in which sufferers from phthisis live and in which sufficient ventilation is lacking; but the argument that consumption is a virulently infectious malady after the same manner or to the same extent as the exanthemata will assuredly not be put forward by any physician in the world. In an editorial which appeared in a recent number of the MEDICAL RECORD the scheduling of tuberculosis was adversely commented on as being a too radical measure, and one that did not altogether appear as likely to have the magical preventive effects claimed for it by its advocates. Notwithstanding these statements, to which, although at all times open to conviction, we still adhere, Dr. March is undoubtedly right when he asserts that the more expeditiously consumptive sailors are removed from the ship the better will it be for the health of the remainder of the crew, and if the fact can be conclusively proven that this event can be brought about only by the scheduling of tuberculosis as a quarantinable disease, then by all means let this be done.

There is, moreover, another phase of the case which is, perhaps, quite as important to the health of the consumptive and to that of his fellow-men as the prompt removal of the sufferer from the ship. Where shall he be taken when removed? If he is transported to the general wards of a hospital, the change will be, as the old saying has it, but "jumping out of the frying-pan into the fire." The hospitals themselves are foci of infection, and the consumptive man is as great a source of danger there as he would be on board ship. The proposition advanced by many physicians of experience, that sanatoria should be established for phthisical seamen, has much to be said in its favor. Passed Assistant Surgeon J. O. Cobb, writing in the annual report of the Marine-Hospital service for 1898, is a strong advocate of this proposal, and says: "Granting the most liberal allowance for faulty conclusions from the data at hand, it is quite probable that the government can build sanatoria for these men, transport them to these places, and take care of them to a termination of the illness, for the amount that would be expended on their care at hospitals. The sanatorium is the ideal method of administration for these cases. At the sanatorium these cases can be closely studied, and all kinds of treatment tried. Taking that, then, to be a fact, the eventual outcome would, from a medical standpoint, be an ideal one." Many difficulties will surely have to be surmounted ere sanatoria for sailors are erected, but, when the hardships of the seafaring class are considered, no trouble or expense should be spared to better the lot of the ailing seaman.

WILL THERE BE CONSCRIPTION IN GREAT BRITAIN?

WHATEVER may be the ultimate result of the Transvaal war, whether the issue will be that a Dutch republic is formed on the ashes of the British colony, or that Great Britain establishes "*vi et armis*" her paramountcy in South Africa, one fact stands out with striking prominence, namely, that the British military system must undergo radical reforms. With the justice or otherwise of the British claims we have no concern, but the comparative breakdown of the methods controlling the management of the British army, and the consequent suggestions thrown out on all sides that some form of conscription should be adopted in the United Kingdom, is a matter of great interest to America. Treating the subject from the standpoint of health and disregarding its influence on the commercial status of Great Britain, there is much to be said in favor of partial conscription. The system in the first instance inculcates habits of discipline and method, and further is calculated to improve the physical well-being of those who practise it. The great argument against conscription in Great Britain itself has always been that it would seriously injure the trade of the country, and is besides directly opposed to that love of freedom inherent in all those of the Anglo-Saxon race. But, as is well pointed out in an editorial in the London *Lancet* of December 23d, the trade of Germany does not appear to have been disastrously handicapped by her military system, and in so far as the physique and general health of her population are concerned has greatly benefited by conscription. The greater part of the inhabitants of Great Britain live in cities and towns, and the melancholy truth that the population as a whole has deteriorated physically owing to this cause is too obvious to be lightly ignored. Two or three years of healthy army life, followed at just that age when a man especially needs to live under favorable sanitary conditions, would do much toward improving the British town-dweller mentally and physically. That the question of conscription is thought worthy of consideration even in Great Britain is a sign of the trend of public opinion, and the Boer war, be the result what it may, will have the effect of making the British "place their house in order."

News of the Week.

What's in a Name?—A Berlin physician recently published an article in the *Therapeutische Monatshefte* extolling the virtues of the "Backhaus-Milch" for infants.

The Death Rate of Dublin has reached such an excessive figure (49 per 1,000) that the lord-lieutenant of Ireland has ordered an official inquiry into its causes.

Professor Schenk, who was recently requested to leave the University of Vienna, has announced his intention to go to some other country, possibly America, and establish himself as a specialist in sex regulation.

"Monatsschrift für Geburtshülfe und Gynäkologie."—The January number of this journal is a "Festschrift" dedicated to Dr. Friedrich Schauta, professor of obstetrical gynæcology at the University of Vienna, in honor of his twenty-five years of medical life.

Measles on David's Island.—A small epidemic has broken out among the soldiers at Fort Slocum, David's Island. There were ten cases the first week. All the patients have been placed in quarantine. There are fifteen hundred men and about one hundred officers on the island waiting for transportation to the Philippines.

Thermometer Fever.—Dr. Benjamin K. Hays, of Oxford, N. C., writes that the physician to a certain female college in South Carolina recently found that the temperature of thirteen young ladies was two degrees above normal, did not vary through the day, and was uninfluenced by quinine. The young ladies felt no inconvenience from this rise of temperature, but the physician forbade their attending school duties, and kept them in the infirmary for two weeks. At the end of this time it was discovered that the thermometer registered two degrees high, whereupon the young ladies were permitted to return to their duties.

The National Pure Food and Drug Congress.—The third annual meeting of this association will be held in Washington on March 7th and following days. The executive committee of the congress in issuing this call directs especial attention to the fact that the National Pure Food and Drug Congress through its authorized committees and officers has since the last meeting of the congress used every effort to secure the passage of the "national pure food bill," indorsed by the congress and introduced in the House of Representatives by Hon. Marriott Brosius, of Pennsylvania. The same bill has also been introduced in the Senate by both Senator Hansbrough and Senator Allen. It is believed that with a united effort the bill can be passed and a national pure food law be enacted during the present session of Congress. It is therefore greatly to be desired that any interest entitled to representation in the congress should be represented at the third annual session.

The Game of the German Emperor.—A cable despatch from Berlin conveys the important information that since 1872 Emperor William has killed 40,822 pieces of game. The list includes 34,813 small game and 6,009 big game, besides 121 chamois, 7 elks, 3 reindeer, 3 bears, and 1 whale. If there happens to be an antivivisection society in Germany, we would commend the German Emperor to the particular attention of its members whenever they may enjoy an interval of rest from baiting scientists.

The Eighteenth German Congress for Internal Medicine will be held at Wiesbaden on April 18–21, 1900, under the presidency of Dr. v. Jaksch, of Prague. The subjects announced for set discussion are "Endocarditis and its Relation to Other Diseases," to be introduced by Litter, of Berlin, and "The Treatment of Pneumonia," to be introduced by Korányi, of Budapest, and Pel, of Amsterdam.

Fysician is the way the agricultural editor of the *East Aurora Journal* is now pleased to designate the practitioner of the noble art of healing. Though advancing in years, he continues to have his monthly periodicals of protest, and doubtless things to protest against grow fewer every year in East Aurora. He is himself, however, such a "Filistine" that he continues to spell the name of his journal with a Ph.

Leprosy in Crete.—Drs. Ehlers, of Copenhagen, and Cahnheim, of Dresden, who made a careful study of leprosy in Iceland in 1894–95, have been requested by Prince George of Greece, the governor-general of Crete, to visit that island the coming spring to study leprosy conditions there. They will go in March and remain about three months, studying especially the origin and spread of the disease in the interior of the island, and making suggestions as to the best means of keeping it in check.

A Discussion of Tuberculosis.—It is announced that a congress for the discussion of tuberculosis will be held in this city on February 21 and 22, 1900, under the auspices of the Medico-Legal Society. The first session will be held at the Hotel St. Andrews, Seventy-second Street and Broadway, at 9 P.M. It will be preceded by a dinner at the same place at 7 P.M., at which it is hoped most of the members will assist.

College of Physicians of Philadelphia.—At a stated meeting held February 7th, Dr. Thomas G. Morton read a memoir of the late Dr. Albert Frické. Dr. J. Dutton Steele read a paper entitled "A Contribution to the Pathology and Diagnosis of Retroperitoneal Sarcoma." He reported the case of a child, in which in the sequence of a fall upon a fence an abdominal tumor developed. The neoplasm was thought to be a sarcoma of the kidney. An operation was performed, and the growth found to be an endothelioma of the retroperitoneal glands. Dr. Arthur V. Meigs made a verbal communication upon the subject of the placarding of houses for contagious diseases. He contended that the present practice of placarding houses in which are cases of contagious disease conduced to concealment and deception in order to avoid the inconveniences attendant upon the quarantine restrictions enforced.

New York State Medical Examinations.—In the examinations for medical license, held in this State in September, 1899, one hundred and sixty-two candidates presented themselves, of which one hundred and twenty-seven, or 78.4 per cent., were successful. Eight men passed with honors. The highest general average was 93.3.

Fecundity.—Dr. W. S. Hulbert, of Winsted, Conn., writes that on February 3d he delivered a woman of her tenth child. The ten children, all delivered singly and at full term, were born within a period of exactly ten years, ten months, and ten days. In this last confinement the patient nearly lost her life from post-partum hemorrhage.

Influenza is evidently pandemic in Europe. It has been reported as seriously prevalent in England, Spain, and Italy, and now it has invaded Central Europe. In Berlin the hospitals are crowded, and there is scarcely a house in which there are not several victims. In Munich the sufferers are numbered by thousands.

Pathological Society of Philadelphia.—At a stated meeting held February 8th, Dr. F. A. Packard presented a specimen of hemorrhagic pancreatitis from an elderly man, who had suffered from abdominal pain, and in whom death had occurred suddenly. Dr. J. Hendrie Lloyd presented sections from a case of hæmatomyelia, the condition having resulted in consequence of a fall down-stairs. There was no fracture or luxation of the vertebræ, although there was paralysis of all four extremities and of the respiratory muscles, except the diaphragm. Drs. M. P. Ravenel and C. Y. White presented specimens exhibiting experimental tuberculosis in a goat. Infection had been induced by intrapulmonary injection of tubercle bacilli, pneumonia developing, and tubercle bacilli being easily found in all of the parenchymatous organs. Typical tuberculosis lesions were wanting. Dr. M. P. Ravenel reported the results of experimental inoculation of calves with syphilitic virus. Two animals treated with the products of active syphilitic lesions failed to develop the slightest indication of syphilis. Drs. H. D. Jump and J. D. Steele exhibited specimens of thrombosis of a coronary artery, contracted kidneys, and malformation of the liver. There had been no symptoms of angina pectoris, and death had resulted from uræmia. A portion of the left lobe of the liver was reflected upon itself.

Red Cross Work in the Philippines.—The special committee appointed by Auxiliary No. 3 of the Red Cross Society to continue in the Philippine Islands the work of selecting and maintaining trained nurses met recently at the residence of Mrs. Whitelaw Reid, in this city. The auxiliary, which was organized for work in Cuba, and was dissolved a year ago, was resuscitated when it was found that there would be work for it in the Philippines. Under the authorization of the Secretary of War, four Red Cross nurses were sent on each of the transports *Grant*, *Sherman*, and *Sheridan*. They cared for five hundred and fifty-two patients during the voyage, and, upon reaching the Philippines, found their services so much in demand that the committee sent a second detachment selected in San Francisco, and later a third detachment selected in New York. At one time over one thousand sick and wounded men were under the sole charge of these nurses. The auxiliary is now sending out libraries to the hospitals in Manila.

Opposition to Reciprocity in Pharmacy Licenses.—The Ontario College of Pharmacy has been notified by the board of pharmacy of Greater New York that in future foreign diplomas in pharmacy will not be recognized in this city, and that candidates for registration here must pass an examination. The reciprocal privileges heretofore extended to New York graduates in Ontario are to be withdrawn.

Rough Voyage of a Hospital Ship.—The hospital ship *Missouri*, which sailed from Manila on January 11th for San Francisco, with two hundred and seventy-two sick and wounded soldiers, had a very unpleasant weather experience after leaving Japan. During the greater part of the trip from Nagasaki to Honolulu no meals could be served at the cabin tables, and the passengers and crew were obliged to receive their food at the galley and eat it standing. Sixteen of the sick men died during the voyage.

New Quarantine Regulations.—A bill has been introduced into the legislature of this State making more stringent the quarantine rules for the port of New York, and giving the health officer and the commissioners of quarantine additional powers to protect the public health in cases of emergency. The health officer is required to live at quarantine. The time during which suspected persons may be detained is extended from ten to twenty days. A vessel found to be in a condition dangerous to public health may be held, and treated as the health officer deems necessary. At present the mayor may order a vessel to quarantine, but the new bill gives the health officer sole power in that respect, and he is to have the aid of the health and police departments in enforcing orders.

Smallpox has appeared in a number of counties in New Brunswick, having been brought there from Quebec, and the authorities are enforcing the health regulations in the hope of preventing the further spread of the epidemic. The disease, which exists chiefly among the employees of the Intercolonial Railroad, is in very mild form, and few deaths have occurred. About sixty cases are under treatment.—In the island of Luzon there has been some increase in the number of cases of smallpox, as is usual at this time of year. Two officers of the Thirty-sixth Volunteer Infantry have died of the disease, and one other is ill. During February and March the disease always becomes more virulent in the Philippines, but there is nothing alarming in the situation. Orders have been issued for the vaccination of the troops, and also of the natives wherever possible.

Competition among Undertakers.—The department of charities of New York City has instituted an investigation of the alleged practice by the employees of the department, of selling information to undertakers concerning the deaths of patients in city institutions. The investigation was begun on the complaint of an undertaker, who was losing trade because, as he said, his rivals were willing to pay high prices for early information.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending February 10, 1900. February 3d.—Passed Assistant Surgeon M. S. Elliott commissioned passed assistant surgeon from October 6, 1899. February 8th.—Medical Director J. A. Hawke commissioned medical director from September 24, 1899. Medical Director R. A. Marmion commissioned medical director from October 23, 1899. Medical Director D. Dickinson commissioned medical director from November 11, 1899. Medical Director M. C. Drennan commissioned medical director from February 5, 1900. Medical Inspector T. H. Streets commissioned medical inspector from April 16, 1899. Medical Inspector G. E. H. Harmon commissioned medical inspector from November 11, 1899. Medical Inspector J. W. Waggener commissioned medical inspector from February 8, 1899. Surgeon T. A. Berryhill commissioned surgeon from April 9, 1899. Surgeon E. P. Stone commissioned surgeon from April 16, 1899. Passed Assistant Surgeon R. K. Smith commissioned passed assistant surgeon from April 3, 1899. Passed Assistant Surgeon R. S. Blakeman commissioned passed assistant surgeon from May 27, 1899. Passed Assistant Surgeon J. C. Rosenbleuth commissioned passed assistant surgeon from October 14, 1899. Passed Assistant Surgeon G. W. Costigan commissioned passed assistant surgeon from February 8, 1900. Passed Assistant Surgeon G. H. Barber detached from the Naval Academy, February 10th, and ordered home and to be ready for orders to sea duty.

The Plague is believed to have been arrested in Honolulu by the extensive fire in the Oriental quarter, no new cases having appeared during the eight days preceding February 2d, the date of the last advices. In all there were forty-six deaths. Ten other blocks outside of Chinatown were burned by order of the board of health, and about fifty isolated buildings were also destroyed. Following the destruction of Chinatown and other similar places the number of deaths from all causes fell off remarkably. The work of inspection was most thorough. The sanitary committee divided Honolulu into forty inspection districts, with a volunteer inspector in charge of each. Each district was divided into sections or apanas, each containing from seventy-five to one hundred and fifty inhabitants, and a volunteer sub-inspector was placed over each. Each sub-inspector went over his apana twice a day, and personally saw each inhabitant, reporting every case of illness, however trivial, to the board of health, which sent a physician at once, and if any plague symptoms were discovered the patient was isolated, and all who had come in contact with the premises were quarantined.—In Manila the disease is reported to be gaining headway. It is said that this is the first visitation of plague the city has ever had. It was undoubtedly brought from Hong Kong, where during 1899 there were 1,486 cases with 1,428 deaths.—In Bombay the conditions are growing worse owing to the influx of famine sufferers, who present a fertile soil for disease of every kind. The number of deaths in that city in one day last week was 408, not all from the plague, however.

The Late Dr. Samuel Ketch.—At a stated meeting of the medical board of the Montefiore Home for Chronic Invalids, held January 16th, the following resolution was passed regarding the death of Dr. Samuel Ketch:

"The medical board of the Montefiore Home expresses profound sorrow at the death of Dr. Samuel Ketch, consulting orthopædic surgeon. As a surgeon Dr. Ketch was skilful, clear-headed, conscientious, and able; as a man, genial, courteous, frank, and loyal. The board records in its minutes with profound grief the death of a valued counsellor, an expert surgeon, an honest man.

"V. P. GIBNEY, JOSEPH FRAENKEL, GEORGE R. ELLIOTT."

Obituary Notes.—DR. T. DANA FITZSIMMONS died at his home in Brooklyn on February 4th, at the age of twenty-six years. He was a graduate of the Long Island College Hospital Medical School in 1897, and later served on the house staff of St. Mary's Hospital.

DR. CHARLES CARROLL SMITH, formerly a surgeon in the navy of the United States, died at his home in Philadelphia on February 5th, aged sixty years. Death was due to locomotor ataxia. He was at one time in charge of the government medical stores at League Island. He was a graduate of the medical department of the University of Pennsylvania.

DR. FRANK STANDISH BRADFORD died on February 8th, at his home in Morristown, N. J., at the age of seventy years. He was a graduate of the Jefferson Medical College in 1858. He practised first in Providence, R. I., then in Charleston, S. C., and served as surgeon of a Rhode Island battery during the civil war. Then he removed to this city, where he remained until 1887, when he went to Morristown. For seventeen years he was professor of the practice of medicine in the Homœopathic Medical College, and for ten years secretary of the faculty.

DR. ABBIE HAMLIN MACIVOR, a homœopathic practitioner of this city, died on February 8th. She was born in 1842, and obtained her medical degree in 1886.

Progress of Medical Science.

Journal of the American Medical Ass'n, Feb. 10, 1900.

A Preliminary Investigation of the Theory of the Inoculation of Malarial Fever through the Agency of Mosquitos.—Albert Woldert gives some results from his study of different species of mosquitos collected in eastern and central Texas, eastern Pennsylvania, and the eastern coast of New Jersey. The writer has made some two thousand sections and examined them microscopically. In determining the relations of mosquitos to malarial infection he considers the study of entomology very important, and says that there is much room for improvement in the classification of mosquitos.

Family Diseases.—F. Savary Pearce divides his subject broadly into: (1) Hereditary maladies; (2) family tendency to a certain disease in special generations without hereditary taint; and (3) special family types of nervous disease, as Friedreich's disease and Huntingdon's chorea. The writer presents notes of over fifty cases, and says that this study leads us to surer ground as to modifications of family disease in making statements about expectation of life in certain classes of them. It also teaches in a negative way the importance of the so-called individual element being given a high place in sociological considerations in health and disease.

The Value of Cycloplegia in Optometric Examination.—C. M. Culver from a review of the records of examination of one thousand eyes deduces the following conclusions: (1) A solution of 2.5 per cent. of homatropine hydrobromate, instilled six times at intervals of five minutes, provides trustworthy cycloplegia in the average healthy human eye in from one to three hours from the first installation; (2) as a rule the protracted use of a one-per-cent. solution of atropine sulphate is no more effective than is the 1 : 40 solution of the alkaloid above mentioned; (3) in ten per cent. of patients it is desirable to produce artificial cycloplegia.

Uncommon Pyogenic Infection of the Middle Ear.—Robert Sattler reports a case illustrating the dangers attending the cauterization of posterior and middle nasal hypertrophies. This danger is especially great in the destruction of posterior hypertrophy, which often results in a fierce resentment on the part of the cauterized region out of all proportion to the slight local injury inflicted.

Clinical and Pathological Notes on Sympathetic Ophthalmia.—H. Gifford reports three cases, each of which indicates three important points, viz.: (1) The absence of premonitory symptoms; (2) the importance of daily tests of vision, and (3) the value of large doses of salicylate of sodium.

Improve the Species.—In this address H. C. Crowell argues from the results obtained through the scientific breeding of domestic animals. He would have certain restrictions and limitations enforced to this end, and concludes by saying: "Degeneracy is the result of fostering or permitting the perpetuation of weakness, moral, mental, or physical."

Foreign Body in the Urethra.—L. M. Greene reports the case of a man who, while using a lead pencil for purposes of masturbation, allowed it to escape into the urethra. After operation and drainage the patient recovered.

Centrifugal Analysis of Urine.—Charles W. Purdy presents tables and describes the necessary equipment and process for this mode of analysis. He claims rapidity, precision, and facility for his method.

Contribution to the Treatment of Spinal Caries, with Special Reference to the Woven Wire Corset.—By George R. Elliott. See MEDICAL RECORD, vol. lv., p. 834.

Contributions of the Medical Profession to General Literature and Collateral Sciences.—By George R. Highsmith. An historical sketch.

Strangulated Hernia; Some Practical Remarks Concerning its Diagnosis and its Proper Management.—By Parker Syms. See MEDICAL RECORD, vol. lvii., p. 299.

Radical Cure of Strangulated Inguinal and Femoral Herniæ.—By Irving S. Haynes. See MEDICAL RECORD, vol. lvii., p. 300.

Treatment of Strangulated Hernia.—By John F. Erdmann. See MEDICAL RECORD, vol. lvii., p. 300.

Diagnosis of Strangulated Hernia.—By Henry Roth. See MEDICAL RECORD, vol. lvii., p. 299.

New York Medical Journal, February 10, 1900.

A Few Clinical Studies of Cardiac Diseases in Infancy and Childhood.—J. Zahorsky narrates a series of clinical histories illustrative of the points brought out in the paper. Endocarditis is often, he believes, diagnosticated as malaria. Pain in the præcordial region is not uncommon in childhood, and tonsillitis may be a frequent cause of pains in the chest. Rarely the agonizing pain resembling angina is found. Visible pulsation he regards as indicative of hypertrophy unless extreme emaciation is present. An accentuated second sound is unreliable in infants but becomes significant in older children. The author advocates the practice of calculating the area of dulness in square centimetres.

Malarial Hæmaturia.—B. Smith closes a continued article upon this subject. He does not believe in cinchonizing the patient as is the general custom, but prefers to rely on mercury and on diaphoresis to eliminate the poison. He believes that the administration of quinine is a source of possible danger, and it has become the custom of the physicians of his section (Texas) carefully to avoid the remedy in malarial hæmaturia. During convalescence it is well to give tincture of cinchona in the cold infusion of wild-cherry bark, to which may be added later small doses of nitro-muriatic acid. The blood state calls for the phosphates of sodium, calcium, and potassium.

The Benefits of Medical School Inspection.—H. G. McAdam describes the system as carried out in New York City. From the quarterly report of the board of health, it is seen that out of 139,965 pupils examined, 7,606 were found to be suffering from communicable diseases.

A Case of Mixed Typhoid and Malarial Fevers.—The patient, whose history is given by J. L. Bevans, was a soldier in the army which had been in Cuba. The blood responded to the Widal test. The malarial organisms were of the æstivo-autumnal type.

A Suggestion for Tablet-Triturate Manufacturers.—C. J. Proben thinks that all triturates containing the more narcotic drugs should be colored red in order to prevent mistakes in dispensing.

Athletics in the Public Schools.—J. Gardner Smith gives an account of the establishment of this department of instruction in the schools of New York City. He believes that half an hour out of every school day should be given to pure bodily improvement.

Fracture of the Patella.—J. B. Bissell reports a case of a man aged forty-eight years in whom complete union was obtained by open operation seven months after the injury.

Recovered Consumptives Who Remain Well.—Paul Paquin tells of twenty-eight persons who have been treated for phthisis during the last few years and are still alive and seemingly well.

Medical News, February 10, 1900.

Atresia Vaginæ; Solid Uterus; Hæmatoma of Left Ovary.—H. J. Garrigues reports the case of a girl twenty years of age who had never menstruated. Every four weeks the patient suffered severe pain. Epileptic convulsions also occurred. Laparotomy disclosed a solid uterus of normal size and shape, with the right ovary slightly enlarged, having a fresh corpus luteum filled with blood. The left ovary was changed into a hæmatoma, containing ten ounces of dark inspissated blood.

The Justo-Major Pelvis as a Factor in the Causation of Perineal Injuries.—Joseph Brown Cooke believes that the frequency of lacerated perinei in patients with justo-major pelves is most rationally explained by the fact that the head does not "mould." It has all the characteristics of a head in a breech delivery.

The Policy of the State Relative to the Spread of Tuberculosis.—By Enoch V. Stoddard. See MEDICAL RECORD, vol. lvii., p. 210.

Report of Bacteriological Investigations upon Yellow Fever.—By Aristides Agramonte. A continued article.

Boston Medical and Surgical Journal, Feb. 8, 1900.

Bradycardia.—Richard F. Chase reports a case with the following conclusions: A pulse rate under 60, synchronous with the heart's systole, constitutes a bradycardia according to Grob. The condition is of common occurrence, especially in men. There are three types: (1) Physiological. (2) Idiopathic, embracing those cases of persistent slow pulse, usually seen in advanced life, and more commonly in male subjects. It is rarely attended by any discoverable cause. The termination is usually fatal, though the patient may live several years. (3) Symptomatic bradycardia accompanies some usually apparent condition, ordinarily of temporary duration. It may, however, complicate cases terminating fatally from injuries, sunstroke, and other serious conditions.

Grave Abdominal Lesions which Often Defy Diagnosis.—Thomas H. Manley believes that immediate section for violent contusions of the abdomen should be discouraged, unless we are sure that a large rent or rupture of a hollow organ is involved. It is a desperate resource of very questionable expediency under any circumstances before reaction is established.

The Massachusetts State Hospital for Consumptives at Rutland.—Vincent Y. Bowditch gives a description of this institution. The work accomplished during the first year has been very satisfactory.

Multiple Cerebral Hemorrhages from Chronic Lead Poisoning.—J. W. Courtney reports a case of this nature and gives in detail the autopsical findings.

Philadelphia Medical Journal, February 10, 1900.

Albuminuria, its Significance and Detection.—Thomas P. Prout discusses first the five proteids found at times in the urine, viz., serum albumin, serum globulin, nucleo-albumin or mucin, peptone, and albumose or propeptone, and then describes six tests which he is accustomed to employ.

Locomotor Ataxia, Recovery in a Case Repeatedly so Diagnosed.—David S. Booth reports a case in a man thirty-seven years old who presented many of the symptoms of tabes. He was under treatment, the nature of which is not stated, for a year, and his symptoms disappeared.

Some Casual Remarks on Prostitution and Venereal Diseases in their Relation to the Public.—Isadore Dyer discusses the means of reducing prostitution and venereal disease—two evils which must be combated together or at least simultaneously.

Celluloid Yarn.—J. Pagenstecher describes a new material for sutures and ligatures. It is linen thread impregnated with a solution of celluloid.

Syphilitic Fever.—A. C. Morgan reports a case of evening pyrexia (100.5°–103° F.) which disappeared after the exhibition of potassium iodide.

Position Symptoms in Joint Disease.—By Harry M. Sherman. See MEDICAL RECORD, vol. lvi., p. 494.

British Medical Journal, February 3, 1900.

Dilatation of the Stomach from the Surgical Aspect.—William H. Bennett says that dilatation of the stomach is now generally admitted for all practical purposes to be a surgical complaint. He believes that the cause of persistent dilatation will be found to lie in permanent pyloric obstruction, in adhesions, or in some other condition outside the stomach interfering with its power of contraction. The writer calls special attention to a class of cases in which exploratory abdominal section having been performed no evidence of obstruction can be made out by manipulating the organ from its external surface, yet in many of these cases pyloric obstruction, sometimes to an extreme degree, exists and is remediable. In all cases, therefore, after abdominal section, the viscus should be opened so that the condition of the pyloric sphincter may be examined.

A Case of Gastrostomy Treated by Franck's Method.—Colon Macvicar thinks that this method is practicable only when little or no cicatricial contraction of the stomach exists. In the case he reports there was no contraction at the time of operation, but probably considerable secondary contraction from the invasion of the cardiac end of the stomach, so much pain resulting from the traction that the operation was a questional gain. The patient lived four months after operation, two or three months longer than the average expectation in malignant cases.

Renal Papillectomy.—E. Hurry Fenwick gives some results of ten years' study of cases of unilateral, painless renal hemorrhages in the young adult. The author is convinced that ignorance of the cause of the hemorrhage is due to faulty operative technique. He says that an examination with the finger is futile; that the pelvis must be opened and every part examined by a strong light.

Removal of a Submucous Fibroid by Section of the Uterus (Myomectomy).—James Braithwaite reports this case. He says that although there are only two other cases of the kind on record, he thinks time and experience will show that it is the proper mode of removing tumors which cannot be removed per vaginam, or which are so large as to require the uterus, or part of it, to be removed with the tumor.

On Removal of the Cancerous Uterus by the Abdominal Route.—T. Henderson Pounds predicts that the operation of the future for the cancerous uterus will be the abdominal one. He says that although this operation has a slightly higher immediate mortality than that by the vaginal route, this is greatly counterbalanced by a much longer respite to the patient in successful cases.

On Suture of Fractured Patella by an Improved Method.—R. Glasgow Patteson thinks that the causes of failure of the various methods of suturing fractured patella may be classed under two heads: (1) The adoption of a subcutaneous method, and (2) the use of unsuitable materials, and a faulty method of open treatment. The author says that in young, healthy subjects the ideal operation is primary suture.

The Disposition of the Utero-Vesical Pouch of Peritoneum in Cases of Distention of the Vagina and Uterus.—Arguing from cases observed W. McAdam Eccles says that when the vagina is distended with fluid, the bladder is drawn up out of the pelvis, the uterus also rising on the summit of the vagina, and thus the natural relationship of the utero-vesical reflection of peritoneum is preserved.

Hemorrhage through the Lacrymal Duct after Plugging the Nares.—D. Richmond reports this case in which the patient suffered from a severe attack of typhoid fever. A sudden fall in temperature from 104° to 98° F. was accompanied by severe hemorrhage from both nostrils. When the nostrils were plugged the hemorrhage took place through the lacrymal duct.

Two Cases of Colectomy.—F. T. Paul describes a mode of operation involving the establishment of a temporary or permanent artificial anus, which he prefers to any of the various methods in vogue for immediately restoring the continuity of the bowel. He reports two cases in which the method has been entirely successful.

A Case of Abdominal Nephrectomy for Renal Sarcoma in a Young Child.—Charles A. Morton reports this case, in which the patient, a child aged eighteen months, was operated on successfully and discharged in good health. There was no local recurrence, but two months after the child succumbed to tuberculosis.

A Case of Sodium-Salicylate Poisoning.—In this case, reported by H. Ainslie Scott, the patient purposely doubled the dose ordered, taking about gr. lxxx. in fourteen hours. She was treated with warm drinks, potassium bromide, and aromatic spirits of ammonia. Until the drug was eliminated there was considerable hallucination.

Complete Atresia Vaginæ.—A case reported by W. E. Fothergill in which careful examination failed to reveal the presence of uterine body, of tubes, or of ovaries. The writer says an artificial vagina will be made should the patient care to undertake the trouble of keeping it open during cicatrization.

Note on a Splint for Use after Amputation.—A. Marmaduke Sheild describes a splint he has devised which, in most cases, may be left on through the whole healing-process, thus obviating the pain and trouble which result from the removal of the usual splint for each dressing.

Kernig's Symptom in Meningitis.—W. J. Buchanan reports a case in which this symptom occurred, and remarks on its great diagnostic value in cases of meningitis.

Cases of Operation for Intestinal Obstruction.—James Taylor reports seven cases of operation for intestinal obstruction. Of these cases three resulted in recovery.

The Lancet, February 3, 1900.

The Value of Eye Symptoms in the Diagnosis of General Diseases.—A series of cases is described by H. F. Juler showing the intimate connection between various eye symptoms and lesions in other parts of the body. A purulent conjunctivitis may prove on examination of the pus to be gonorrhœal. Diphtheria frequently affects the eye muscles and sometimes the globe coverings. Syphilis may show itself as chancre of the lids, inflammation of the iris, and keratitis. Renal affections are frequently inaugurated by an albuminuric retinitis, and the eye symptoms may be the most prominent feature of many maladies of the nervous system.

Some Complications following Injuries about the Elbow-Joint and their Treatment.—In a clinical lecture by H. Littlewood he describes a peculiar deformity following elbow injuries which he has never seen mentioned in the books. The deformity is this: when the wrist is extended, then the interphalangeal joints of the fingers and thumb are strongly flexed so that the tips of the fingers touch the lower part of the palm and no reasonable amount of force appears capable of straightening them, but as soon as the wrist joint is flexed at a right angle then the interphalangeal joints can be easily extended.

Septic Lymphangitis Along the Ureters Affecting the Kidneys, Treated with Anti-Streptococcic Serum: Recovery.—J. W. Stenhouse gives the history of a woman aged twenty-eight years. The disease followed a urethritis of several years' standing and a later cystitis. The use of the serum gave prompt results, and it is recommended to combine with it the administration of full doses of quinine.

The Treatment of Imperforate Rectum.—W. P. Montgomery analyzes ten cases, in nine of which colotomy was performed. Seven of the patients died within seven days after operation. The others were living at last accounts. The relative advantages and disadvantages of the perineal and iliac operations are fully discussed.

Some Reflections upon Appendicitis.—J. O'Connor takes the usual surgical position in regard to operative intervention. He finds in an adherent appendix, and in an abnormally short meso-appendix, explanations of many of the symptoms of the relapsing cases not operated on at the time of first attack.

Some Experiments on the Sterilizing Properties of Unconfined Superheated Steam.—L. Cobbett and J. H. C. Dalton show by a series of experiments that this agent may be used to disinfect bedding, that it leaves it dryer than before, and that the time required for the process is not inconveniently long.

Day-Terrors.—G. F. Still describes a condition analogous to night-terrors which is due to a rheumatic inheritance, fright, and mucous colitis. In such children all forcing must be avoided and a careful search made for the exciting cause.

Further Observations on Pernicious Anæmia as a Chronic Infective Disease.—By W. Hunter. A continued article.

Berliner klinische Wochenschrift, January 22, 1900.

On the Poisonous Effects of Normal Urine.—C. Posner and M. Vertun call attention to the experiments of Bouchard, who found that the introduction into the veins of animals of urine at blood heat caused myosis, dyspnœa, lowering of temperature, and somnolence, the animal dying without convulsions. The introduction of the fluid mass itself regardless of its nature may be fatal from thrombus in the right heart or from lung embolus. Their own experiments lead to the same general conclusions, but account must also be taken of the degree of toxicity of the urine as well as of its bulk. Furthermore, results vary according to the saline percentages in any given urine.

Pneumatic Therapy from 1875 to 1900.—J. Lazarus describes the measures employed along this line in one of the Berlin hospitals, and finds from the experience of the last quarter-century that pneumatic therapy gives definite results in pleurisy, lung retraction, and chronic infiltration, chronic bronchial catarrh, consecutive circulatory disturbances without organic cardiac disease, and in certain anomalies of nutrition, as chlorosis and anæmia. The limitations and contraindications of the method are clearly pointed out. Cases of hæmoptysis especially are not to be subjected to this plan of treatment.

The Bacterial Contents of Milk Products and Other Nutritive Media.—Dr. Bloch has investigated this question with reference to preparations called plasmon, nutrose, eulactol, hygiama, tropon, etc., also including in his researches meal and oatmeal. In no instance did he fail to find large numbers of bacteria, but says that the utility and safety of a food product are to be based not on the number but the kind of bacteria found therein. Condemnation is rightfully made with reference to those substances which contain micro-organisms which are definitely known to be injurious to the human body.

The Development of Ophthalmology in the Nineteenth Century.—J. Hirschberg closes a historical article with the statement that a large and grateful field of activity awaits the physician who devotes his energies to ophthalmological practice, and expresses the hope that the coming century will see the members of the profession better acquainted with its principles.

Simultaneous Gunshot Wounds of the Thoracic and Abdominal Cavities.—By F. Koenig. A continued article.

Deutsche medicinische Wochenschrift, January 18, 1900.

Further Investigations of Arrow Poison.—Brieger, having previously studied the arrow poison of the Vakamba in East Africa, now reports on that used by the Vagogo in the same part of the world. He thinks these two poisons, as well as that of the Somali, are practically the same. He had not sufficient material to enable him to identify the poison with certainty, but it is probably composed in great part of the juice of a species of euphorbia.

Traumatic Tetanus Cured by Means of Orrhotherapy.—Crone reports a case of tetanus in an eight-year-old boy who, in a fall, received a scalp wound. The first symptoms appeared ten days later. It was four days after the disease declared itself before the tetanus antitoxin was procured. Four injections in as many days were made before any improvement was noted, but then the boy began to grow better, and finally recovered entirely.

A New Method for the Quantitative Estimation of Mercury in the Urine.—Friedrich Eschbaum obtains a union of the mercury in the urine with copper in the usual way, breaks up this union by heat, and then removes the mercury from the sides of the test-tube by means of a little plate of metallic silver. The difference in weight of this piece of silver before and after the amalgamation gives the amount of mercury.

Further Contributions to the Study of the Osmotic Pressure of Animal Fluids.—M. Senator studies the density of the urine and of the blood in health and disease by means of observation of the varying freezing-point of these fluids.

Clinical and Experimental Studies of Dural Infusion.—By Paul Jacobi. A continued article.

Münchener medicinische Wochenschrift, Jan. 23, 1900.

Pathology of Miliary Tuberculosis.—Georg Mayer cites the case of a man twenty-one years old, who when first seen had a slight cough with expectoration and shortness of breath on exertion. There were fine bubbling râles over the left upper lung. The pulse was soft and weak. On the right wrist was a small, bright-red area exuding a yellowish-white secretion. No tubercle bacilli were found in the sputum. In less than three weeks there were a severe cough, vomiting, and rise of temperature. There was swelling of the skin of both thighs. Both liver and spleen were palpable. The blood count showed white to red corpuscles as 1 : 720. Later, there were abundant râles over both lungs. The heart became weak and irregular. On the day of death the heart sounds were almost obscured by a loud friction murmur. The patient had no subjective discomfort till shortly before death, which occurred about a month after he was first seen. Section disclosed miliary tubercles throughout the lungs. In the pericardium were 200 c.c. of serous fluid. Both endocardium and myocardium were affected. In the heart cavity were thrombi. Mayer appends photographs showing a tuberculous hair follicle, a tubercle of the cephalic vein, and an organizing thrombus of the right ventricle.

Treatment of Chronic Constipation in Childhood.—Heinrich Doerfler has for the last six years met with flattering success in the treatment of chronic constipation in children by the administration of butter. It should be fresh and of the best quality. It should be given in the natural state and not by means of any vehicle. For the first month clysmata may be given; in the second and third month from a half to a whole coffee-spoonful of butter daily, morning and evening, till the stools are normal; then only every two days. The dose is further increased according to the age.

Local Disposition, Cold, and Hardening.—Carl Kisskalt, in reviewing the results of experiments on animals, says that arterial hyperæmia increases the tendency to illness. Such increased disposition through arterial hyperæmia of the internal organs, including the mucous membrane of the respiratory tract, occurs through the contraction of the skin vessels by cold. Hardening against the influence of cold brings about a condition in which the skin vessels do not contract so quickly, and thus disposition to disease is not so great.

The Separation of Carbonic Acid by Repeated Cold Baths.—A. Lode and A. Durig report as the result of their experiments an extraordinary increase of the production of carbonic acid during and after cold baths. The amount increased when the temperature of the water was lowered, and *vice versa*.

The Œsophagoscopic Diagnosis of Diverticula of the Œsophagus.—Gustav Killiar, in using the œsophagoscope, always has the patient in a sitting position. He then inserts the tube into the sac, then down into the œsophagus, then again into the sac, thus obtaining a clear idea of all the anatomical relations.

A Case of Potassium-Iodide Parotitis.—G. Trautmann states that symptoms of poisoning by the iodine preparations can be caused by their local application as well as by their internal administration. He then cites two cases of parotitis caused by potassium iodide. One of these he takes from the literature; one came under his own treatment.

Father Bernhard, a Predecessor of Kneipp. A Chapter from the History of the Water Cure.—Julian Marcuse relates that Father Bernhard believed in the use of fresh water mixed with ice or snow in three ways: (1) External application of cloths saturated in the liquid, or as a kind of massage by rubbing with pieces of ice; (2) as a drink; (3) as clysmata.

Tuberculosis of the Lymph Glands.—Von Noorden shows by statistics how common this affection is, and declares that the association of tuberculosis of the lymph glands and pulmonary tuberculosis is extremely common.

The Measure of Blood Pressure by Gärtner's Tonometer.—Hugo Weiss believes Gärtner's tonometer to be of great clinical use, and he calls attention to its simplicity.

Wiener klinische Wochenschrift, January 25, 1900.

The Radical Operation for Varicocele.—Albert Narath describes this operation and gives some of its advantages. The incision is made above Poupart's ligament, and thus is in a region more easily sterilized and less liable to infection than the scrotum. The circulation in the internal spermatic vein is entirely interrupted and the high blood pressure is suspended at the origin of the veins. The injury of the internal spermatic artery can be more easily avoided than in other methods. The external spermatic veins are much expanded, so they can be easily resected. At the same time inguinal herniæ and lipomata can be operated. The inguinal canal can be securely closed. The spermatic cord can be raised and embedded in a narrow canal. The operation is very neat; the venous plexus remains intact, the loss of blood is small.

Multiple Stenoses of the Small Intestine of Tuberculous Origin.—Sigmund Erdheim has observed in a short time five cases of this nature and has operated on some of them. In four of the cases the position of the stricture was entirely in the small intestine, in the fifth it was combined with a tuberculous stricture of the ascending colon. Combination with tuberculous stenoses of the large intestine, especially of the cæcum, is often observed. All five of Erdheim's cases were secondary infections.

The Technique of Gastrostomy.—Robert Lucke describes this method thus: First a purse-string suture is made in the stomach wall. A trocar is inserted, and after its withdrawal a rubber tube is substituted and the suture drawn up and tied.

Wiener klinische Rundschau, January 21, 1900.

Indication for Employment Therapy in Functional Nervous Diseases.—Oskar Vogt declares that work as a therapeutic measure can be considered only when it is effectual in distracting the patient's attention from himself and when he is happy in its performance. Work is indicated in nervous prostration when it tends to relieve this condition. It is not of much benefit in akinesia algera according to Vogt's experience. But for neurasthenics with hypochondriacal tendencies and for such affections as are allied to neurasthenia it is admirably adapted.

Epiploitis following Operation.—Julius Schnitzler tabulates twenty-eight cases, the patients ranging in age from seven years to sixty-nine years. Both sexes are represented. Some of these terminated by spontaneous healing, some were subjected to further operative interference.

Two Cases of Tuberculosis of the Serous Membranes in Man, with the Macroscopical as well as the Microscopical Picture of Bovine Tuberculosis.—By Josef Pelnár. A continued article.

French Journals.

Hemiplegia and Aphasia in Intestinal Helminthiasis.—E. Maragliano makes an exhaustive study of a patient found unconscious on the street with no history obtainable. Melæna passed was examined and found to contain the larvæ and eggs of the ankylostoma. There was right hemiplegia with aphasia. The literature of anæmia from ankylostomiasis is passed in review. The worm in the intestines exercises its perturbing action on the circulation in absorbing the blood directly through the mucous membrane; in setting up hemorrhages and in secreting toxins. The various possibilities in the case in point are analyzed, and the conclusion is reached that morphological changes in the red globules were produced, which in turn determined a cerebral hemorrhage. The treatment consisted in a tannin injection in one-per-cent solution, followed the next day by a 2-gm. cachet of thymol every three hours for four doses, and two injections daily of 1 gm. of ergotin.—*La Médecine Moderne*, January 28, 1900.

Surgical Treatment of Club-Foot by Astragalectomy.—P. Mauclaire relates an instance of varus equinus of paralytic origin coming on at the age of eleven months. Infantile paralysis implicated both legs and compelled rest in bed for seven months, at the end of which time there was considerable turning in of the right foot. At the age of three years tenotomy of the tendo Achillis was done without benefit. The condition was in reality due to paralysis, the club-foot becoming fixed because of tendinous retractions and of subluxation of the astragalus forward and inward. Radiography made a positive diagnosis possible, and this procedure, the writer thinks, should be the guide to treatment in all cases. In the present instance, after the impeding bone was removed, the foot was put into good position and a plaster bandage applied for twenty-five days. The results were good.—*La Presse Médicale*, January 31, 1900.

Acute Pott's Paralysis Without Changes in the Spinal Cord.—H. Verger and Ant. Laubie give the observation of a man, aged fifty-six years, without deformity of the vertebral column, who suffered from retention and weakness of the limbs followed by complete paraplegia and death about a month later. At the autopsy large tuberculous lesions of the bodies of the seventh, eighth, and ninth dorsal vertebræ were found. The cord was not compressed, and there was no change to be seen by the naked eye nor by the microscope.—*Le Progrès Médical*, January 27, 1900.

Mental Pathology at the End of the Nineteenth Century.—Roubinovitch studies the pathogeny of mental alienation, its pathological anatomy, methods, types, curability, and medico-legal aspects. Purely medical methods of study founded on general pathology are advocated, while the newer psychological methods are useful as contributing aids. Insanity is a material disease of the brain or of the entire organism; it is not a disease of the spirit or of the soul, which being immaterial cannot be diseased.—*Le Bulletin Médical*, January 25, 1900.

The Plague in Ancient and Modern Times and its Future in Europe.—Ph. Hauser makes a historical study of plague, which appeared in continental Europe in 543, and traces its march down to recent outbreaks. In its early pandemic form it was fatal in ninety per cent. of those attacked. From 1720 on the plague disappeared from Europe without known cause, but remained endemic and epidemic in Asia Minor, Syria, and Egypt until 1845. The Hong Kong epidemic of 1894 and the Bombay outbreak receive especial attention.—*La Médecine Moderne*, January 31, 1900.

Appendicitis and Gastrorrhagia.—E. Kirmisson refers to a similar instance reported last month by Piéchaud, and relates the history of a girl of seven years upon whom he had operated. A few hours afterward there was vomiting of blood and eight hours later death occurred. There was no hæmophilia to account for this outcome, and the most probable hypothesis was thought to be that of septicæmia.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, January 31, 1900.

The Cure of Drunkenness by Anti-Alcoholic Serum.—Legrain reviews the various quack and other methods which have been in vogue in alcoholomania, and concludes that they all depend largely if not wholly upon the patients' own efforts for their success. The best prescription is "an infusion of a little will power and earnest desire in an abundance of water."—*La Presse Médicale*, January 28, 1900.

Annals of Gynecology and Pediatry, January, 1900.

Cervical Flexions—their Importance and Means of Curing them.—T. J. Bell believes that cervical flexions do not command the attention which their importance demands. Dysmenorrhœa in unmarried and married women, with sterility in those who are married, should raise a suspicion of flexion at the internal os. Correction of flexions at the earliest possible moment should be advised, and the method employed should be thorough.

Beef-Gall Enemata in the Treatment of Post-Operative Obstinate Constipation and Intestinal Obstruction.—F. C. Ameiss declares that, after the failure of simple means, enemata of eight ounces of beef-gall and eight ounces of water have in several of his cases obviated the necessity of reopening the abdomen.

New Applications of the Undulating Current in Gynecology.—G. Apostoli affirms, after an experience of three years with this current, that while being harmless and well borne, it deserves to take rank in the therapeutics of conservative gynecology because of its two chief actions, on the one side analgesic, on the other tending to resolution and the relief of congestion.

Two Cases of Vesico-Vaginal Fistula.—John O. Polak very carefully describes the closure of these two fistulæ. The first consisted of several plastic operations at different sittings. The second patient was kept in bed in the right latero-prone position. The edges of the fistula were stimulated with fused silver nitrate. Both results were satisfactory.

The Different Phases of Electric Treatment.—J. McFadden Gaston speaks of the various sources of electricity and mentions the favorable results of its use in extra-uterine pregnancy, its application in the case of tumors and of goitre, varicocele, and hydrocele. He speaks of the *x*-ray in the treatment of diseased organs.

Tubal Pregnancy with Report of Cases.—J. M. Black writes that the etiology of this condition is still shrouded in mystery. It may occur at any age, and in a woman who has borne several children, or it may happen in the first pregnancy a few months after marriage.
